THE BOOK OF USEFUL KNOWLEDGE

A CYCLOPÆDIA

OF SIX THOUSAND

PRACTICAL RECEIPTS,

AND

COLLATERAL INFORMATION

IN THE

ARTS, MANUFACTURES, AND TRADES,

INCLUDING

Medicine, Pharmacy, and Domestic Economy.

DESIGNED AS A COMPENDIOUS

BOOK OF REFERENCE

FOR THE MANUFACTURER, TRADESMAN, AMATEUR, AND HEADS OF FAMILIES.

BY ARNOLD JAMES COOLEY,

PRACTICAL CHEMIST.

ILLUSTRATED WITH NUMEROUS ENGRAVINGS.

NEW YORK:

D. APPLETON & COMPANY, 200 BROADWAY.

1854.

PUBLISHERS' PREFACE.

The "Cyclopædia of Practical Receipts" being now completed, it is proper to offer to the reader a few preliminary remarks, concerning the nature and contents of the work to which his attention is directed. From the Author's Preface to the second edition of his Cyclopædia, recently issued in London,—from which this volume has been reprinted,—we extract the ensuing paragraphs, comprising nearly the whole of his original Preface.

"The design of this work is to present an accurate and compendious collection of formulæ and processes, with a variety of information suitable to the general reader, and practical purposes.

"In the performance of the laborious task of compilation, the principal aim has been, to render this work as extensively useful as possible, as well as a correct, comprehensive, and conveniently arranged manual of reference on the subjects on which it treats. It will be found to contain directions for the preparation of several thousand articles of interest and utility, together with their properties, uses, and doses, and the means of ascertaining their purity, and detecting their presence in other compounds. In most cases, the derivations of the names, and a short historical notice of the more important substances have been appended; and the various scientific and technical terms that occur have been generally defined, for the purpose of rendering the work as self-explanatory as possible. As the names of substances, especially those employed in chemistry, pharmacy, and medicine, have undergone repeated alterations, and even at the present day frequently vary as applied by different individuals, the old and new names, and the usual synonymes, English, Latin and Continental, have been introduced, for the purpose of preventing mistakes, and facilitating reference to more elaborate works. A general, rather than a scientific arrangement has been adopted, because the object of the work is popular and universal; and though useful to men of science, it is more especially addressed to practical persons and the public at large. Theoretical reasonings have been avoided, except in some instances, where a slight knowledge of scientific principles seemed necessary to the proper application of practical detail. The whole book will form a compendious Dictionary of Reference for the manufacturer, tradesman, and amateur, as well as the heads of families; and there are few persons who will not find, on looking over its pages, some article that will interest them.

"The sources from which the materials of the present work have been derived, render it deserving of the utmost confidence. The best and latest authorities have been invariably resorted to, and innumerable volumes, both British and Continental, have been consulted and compared. A large portion of the work has been derived from the personal experience of the Editor, and the processes of various laboratories

and manufactories, many of which he can highly recommend, from having inspected their application on an extensive scale. The indiscriminate adoption of matter WITHOUT EXAMINATION, has been uniformly avoided; and in no instance has any process been admitted, unless it rested upon some well-known fact of science, or came recommended on good authority. In the majority of cases, the sources of information have been indicated, for the purpose of enabling the reader to form a proper estimation of their value. Wherever this is not the case, in reference to borrowed formulæ or facts, the omission has arisen from the impossibility of accurately determining to whom the merit is due. The individual names that appear in the work, are those of the persons to whom the immediately attached information or formulæ are usually attributed, or on whose recommendation or authority they have been taken.

"It has been endeavored to avoid confusion of the medicinal weights and measures, with those commonly used in trade and commerce. For this purpose, it was deemed advisable to employ the usual signs or characters to indicate those denominations of either, that do not correspond in value. The quantities would have been gladly brought to one uniform standard, had such an attempt been practicable. The method adopted in this particular, will be found both simple and accurate.

"The nature of a condensed alphabetical arrangement not permitting numerous individual articles to come under distinct heads, the casual reader may often be led to suppose this work most deficient, where in reality it is most copious. Thus, on searching for Hydrocyanic Acid under H, or Picric Acid under P, such an article will not be found; but on reference to the heads Prussic Acid, and Carbazotic Acid, other names for those articles, much valuable matter on those subjects will be met with. In like manner, a vast number of pharmaceutical preparations, as Pills, Lotions, Ointments, &c., will be found mentioned in the remarks that follow the notice of their principal ingredients. Many extensive subjects are also necessarily dispersed under several distinct heads. Thus, information on the manufacture of LIQUEURS will be found under the heads, Cordials, Crêmes, Balms, Oils, Anisette de Bordeaux, Sighs of Love, Parfait Amour, Noyeau, Ratafia, &c.; on PERFUMERY, under the heads, Eaux, Esprits, Essences, Extracts, Pommades, Poudres, &c.; on DYEING, under the heads, Calico-printing, Dyeing, Archil, Annotto; Blue, Brown, Black, and other Dyes; Alumina, Tin, Mordants, Chloride of Tin, Brazil-wood, and Indigo. By a little attention, such divisions may be referred to, and readily compared. Sufficient directions are appended to the various processes, to enable even those who are unacquainted with chemical manipulations, to apply them with success."

The work has been reprinted exactly from the last London edition, with one exception, which must be stated. After the volume was begun, it was discovered that there was a large number of references to articles which are not comprised in the miscellany. It appears that the compilation was entered upon without any distinct survey of the multifarious materials appertaining to such a Cyclopædia; and therefore, constant directions were superadded to the same or analogous substances or preparations, which it was designed should be embodied in subsequent portions of the alphabetic classification. Early, however, in the progress of the volume, it must have been ascertained that, by following out that unrestricted introduction of subjects, the Cyclopædia would have been a book, "de omnibus rebus, et quibusdam

aliis;" and whether it could have been completed to the word FINIS, during the life-time of the Author, is very problematical. Those supernumerary explanations, consequently, were omitted. Hence it became necessary to subject the book to a close examination, that all those fictitious references might be excluded, and the reader thus be saved the trouble of turning over the volume for expected information, which the work does not contain in the form specified, but which is really included in the primary articles. Among the continual variety of those irrelevant references, it is possible that a few of them may have been unwittingly overlooked; otherwise, they have been erased; and thus the reader has been saved indefinite perplexity, in not obtaining, as might be supposed, the requisite intelligence upon the subject which he was investigating.

The Publishers, therefore, now present to the mistresses and managers of domestic economy, and to the various classes of experimental artisans, and men of business, both operatives and traders, a volume which is universally admitted to be very superior to every preceding collection of receipts, for general utility. The whole series is the result of actual scientific tests, and presented in a very lucid manner; combining the utmost economy and utility, with elegance and easiness of attaining the object desired.

Moreover, while it constitutes the best manual that exists, for family use, for the culinary and the other departments of household life, the "Cyclopædia of Practical Receipts" will be of peculiar advantage to the dairyman and the farmer; and for all the manufacturers and mechanics to whom Ure's Dictionary of the Arts and Sciences is a hand-book, Cooley's "Practical Receipts" is an essential accompaniment, as developing the minute, familiar processes inculcated in that large and profound development of modern discovery and science.

gall. Do.
qt. An imperial quart.
O. An imperial pint.
pt. Do.
cwt. A hundred-weight of 112 lbs. avoirdupois.
qr. A quarter of a hundred-weight, of 28 lbs. avoirdupois.
lb. When preceded by Arabic figures, a pound, *Avoirdupois*, of 7000 grains.
lb. When followed by Roman numerals, a pound, *Troy*, of 5600 grains.
℥ A Troy ounce, of 480 grains.
f℥ A fluid ounce, or 1-20th of an imperial pint.
oz. An avoirdupois ounce, of 437½ grains.
dr. A drachm, or the 1-8th of an ounce.
ʒ A Troy drachm.
dwt. A pennyweight, or 24 grs.
fʒ A fluid drachm, or the 1-8th of a fluid ounce.
℈ A scruple, or 20 grains.
♏ A minim, or drop, of 60 to the fluid drachm.
Drop Wherever this word occurs, a minim is intended.
gr. grs. A grain, or grains Troy.

CYCLOPÆDIA

OF

PRACTICAL RECEIPTS.

ABERNETHY MEDICINES. These originally consisted of a three-grain mercurial pill, administered over-night, followed by an aromatized black draught in the morning. Finding, however, that when frequently taken they produced salivation, which proved injurious to their sale, the proprietor lessened the quantity of blue pill, and added a proportionate weight of compound extract of colocynth. Two grains of the former, and three grains of the latter, are the quantities generally adopted for an adult, followed by about an ounce of the draught, as above mentioned. When this is not agreeable, a dose of castor oil, or any mild purgative medicine that the patient may fancy, will prove equally efficacious.

ABIETIC ACID. M. Baup has given this name to an acid principle which he found in the resin of the pinus abies. Caillot has applied the same name to a resinous acid which he discovered in Strasburg turpentine and common frankincense. Berzelius regards it as a mixture of the resins alpha and beta of the above turpentine.

Prep. Digest the resin of the pinus abies, first in weak and afterwards in strong alcohol, mix the two liquors, filter and evaporate; dissolve the residuum in strong alcohol, filter and again evaporate. It may be further purified by resolution, forming a salt of copper by adding a solution of verdigris, and afterwards decomposing it, by the addition of hydrochloric acid.

Remarks. In its purest state it crystallizes in square plates, dissolves in alcohol, and forms salts with the alkalis. It is probably a mixture of the pinic and sylvic acids.

ABIETINA. *Syn.* ABIETIN, ABIETINE. A crystallizable resin found in Strasburg turpentine. (Caillot.) Berzelius says it is the resin gamma of the same turpentine. (Jour. de Pharm. xvi. 436.)

ABORTION. The expulsion of the human fœtus, after the sixth week, and before the sixth month of pregnancy. In its most extended sense, the term has been applied synonymously with miscarriage. The latter term, however, has been generally restricted to the first six weeks after conception. The expulsion of the fœtus after the sixth but before the ninth month, is termed premature labor.

Causes. Nervous irritability, plethora, advanced age, scurvy, syphilitic, scrofulous, or mercurial taints, malformation of spine or pelvis, luxurious and indolent habits of living, excessive indulgence of the passions, extreme terror, anger, joy, &c.; falls, blows, violent exercise, vomiting, coughing, and rough purgatives; hot baths, stimulating liquors, and other excitants generally.

Treat. I. *Prevention.* Avoid all the above-mentioned exciting causes, and immediately on the appearance of any suspicious symptoms seek a recumbent posture, and repose in every shape practicable. A dose of castor oil, confection of senna, or other mild aperient should be taken, and should there be much hæmorrhage, injections of cold water, or cold infusion of black tea, must be had recourse to. A cold hipbath, or sponging the lower part of the body with water and vinegar, often proves successful. Should the symptoms continue unabated, medical assistance should be sought.

II. *Recovery.* Should the preceding measures prove ineffectual, and no violent symptoms supervene, the remaining treatment may consist in continuing the recumbent posture, keeping the bowels regular, taking a light nutritious diet, and avoiding exposure to draughts of cold air. This treatment may be gradually abandoned by the patient for her usual course of life, in proportion as she feels herself able to do so. In many cases, however, the only treatment required throughout, is simply the adoption for a few days of the recumbent posture, gentle laxatives, and a light nutritious diet. Various formulæ for medicines suitable to the above will be found in the body of this work.

ABRACADABRA. A word supposed by the Cabalists, and by other weak-minded and superstitious persons, to possess great virtue in preventing and curing fevers, especially intermittents, (ague,) of which the kind called semi-tertian was

believed to be most easily removed by its incantation. The formula has been preserved by Serenus Samonicus, and its application as an amulet may be seen described in Defoe's 'History of the Plague in London.' A paper with the Abracadabra written on it, and worn round the neck, was thought to propitiate a Syrian deity of that name. The words Abrabax, Abrasax, Abraxas, and abracadabra, are doubtless closely connected together in their origin and import, but tracing them back into the confusion and superstition of the past, would occupy more space than can be devoted to the subject here, and be of too theoretical and speculative a character for a practical work.

Formula from Serenus Samonicus.

A

ABRASION. A superficial injury of the skin, resulting from the partial removal of the cuticle by friction.

Treat. When the injured surface is small, and unexposed, no application is generally required, but when the reverse is the case, it is proper to protect the unsound part from dirt and further injury, by applying a piece of lint or soft linen rag, covered with spermaceti or some other simple unguent; a piece of strapping, or bandage of any sort, may then be placed over it, to keep it on. In most cases, however, a simple piece of strapping, or sticking-plaster, will be found quite sufficient.

ABSCESS. A tumor or swelling in the membranous or fleshy parts of the body, resulting from inflammatory action, and the consequent formation of purulent matter.

Symp. I. *Acute Abscess.* Active inflammation rapidly terminating in the production of pus or matter and the increase of the tumor. The latter may be felt fluctuating within the part, if near the surface; an uneasy sensation of weight follows, the swelling assumes a conical shape, and what is popularly known as a head or point; the skin reddens, and gradually becomes thinne , until at last it breaks, and the imprisoned matter escapes. In favorable cases, healthy action follows, the injury is repaired, and the wound heals. In some cases instead of the tumor bursting, the whole of the matter is absorbed into the blood, and the swelling disappears, whence sometimes disagreeable consequences have resulted, but as frequently without any perceptible derangement of the general health.

II. *Chronic Abscess.* This generally occurs in scrofulous constitutions, and is usually confined to the lymphatic glands and cellular tissue. The symptoms up to the period of the discharge of the matter are of a similar kind to those just described, but with a much less degree of inflammation. At this point, however, the latter increases, fever is excited, and the discharge continues, producing debility and sometimes fatal results. In favorable cases, the healing and reparative processes are similar to those of the *acute* variety, but much more tedious, the *curative* action often *barely keeping pace* with the *injurious effects* of the ulcer, even in its improving condition.

Treat. Cooling applications, friction, and continued gentle pressure may be tried in the early stages, and, if ineffectual, suppuration should then be promoted by warm poultices and fomentations, accompanied by a liberal diet until the rupture of the tumor; when this takes place, the ulcer must be regularly dressed twice a day with simple ointment, and kept perfectly clean; a light nutritious diet should now be adopted, and the bowels kept gently open with mild aperients. When the abscess is situate in the head, chest, joints, near the eye, or other part where its presence may be productive of serious injury from pressure or diffusion, it should be opened with a lancet as soon as mature, but this operation had better be performed by a surgeon. Chronic abscesses require to be opened earlier than acute ones, but in other respects their treatment is similar.

ABSINTHIC ACID. A peculiar acid found by Braconnot in the artemisia absinthium, or common wormwood, where it exists in combination with potash.

Prep. Add a solution of acetate of lead to a watery infusion of common wormwood, wash the precipitate in cold distilled water, then suspend it in water contained in a tall vessel of glass, and pass sulphureted hydrogen gas through the liquor, until all the lead is precipitated; lastly, decant the clear liquid and evaporate.

Prop. Sour, uncrystallizable, deliquescent, solid, forming salts with the bases, called absinthates. These may be procured by double decomposition from a mixture of absinthate of ammonia, and a solution of the metallic oxides. Some of these salts are crystallizable.

Remarks. It has lately been asserted that this acid is similar to the succinic, if it be not actually the same.

ABSINTHINE. *Syn.* ABSINTHIN, ABSINTHINA, ABSINTHIA. The proximate bitter principle of the artemisia absinthium, or common wormwood, discovered by Caventou in the watery infusion of the tops and flowers, and called by him the "pure bitter principle."

Prep. Precipitate an infusion of wormwood with another of acetate of lead, pass sulphureted hydrogen gas through the filtered liquor, until the excess of lead is thrown down, then filter and evaporate to dryness; digest the residuum in a mixture of alcohol and ether, and abandon the solution to spontaneous evaporation. Collect the ramified brown product, redissolve it in alcohol, treat it with charcoal, filter and again evaporate, and repeat this operation until the absinthine is rendered quite white.

Prop., Uses, &c. When quite pure, white, semi-crystalline, and very soluble in alcohol. Its physiological effects, as far as known, are similar to the extract of wormwood. It flavors the milk and flesh of animals in the same way as the plant from which it is procured. It has been proposed

as a remedy for dyspepsia, and as a substitute for quinine in intermittents. *Dose.* Unascertained.

ABSORBENT, ALKALINE. *Prep.* Mix 4 oz. of lime water with 1 oz. each of liquor of potassa and sirup of orange peel. *Dose.* One tablespoonful in a cup of water or broth, in dyspepsia and heartburn.

ABSORBENT, AROMATIC VOLATILE. *Prep.* I. Carbonate of ammonia 2 dr., pure water 5 oz., sirup of orange peel 1 oz., mix, for a six-ounce mixture.

II. Sal volatile 1 oz., water 4 oz., orange sirup 1 oz., mix, and keep it in a well-corked bottle. *Dose.* As last.

Remarks. This preparation is much esteemed as a mild antacid by persons laboring under dyspepsia, heartburn, or acidity of the stomach, arising from excessive indulgence in spirituous or fermented liquors. It also possesses considerable stimulating properties, and will *partially* remove the fit of drunkenness.

ABSORBENTS (IN CHEMISTRY.) Substances that possess the property of withdrawing moisture from the atmosphere that surrounds them. Absorbents are distinguished from deliquescent salts. The latter attract moisture and dissolve therein, while the former merely absorb or suck it up into their pores, in the same way as a sponge does water.

Process of ascertaining the absorbent power of different substances. Thoroughly dry the article by the suitable application of heat, and transfer it, while still hot, into a clean dry vial furnished with a perfectly tight ground-glass stopper. When quite cold, place the substance in a prepared large wide-mouthed glass bottle, which must then be closed, and kept so for some time. A delicate hygrometer being then introduced, will indicate on its scale the degree of dryness of the enclosed air. The atmosphere in the large bottle should be rendered as damp as possible, by suspending moistened rag or filtering paper within it, previously to the introduction of the substance to be examined.

Remarks. Experiments of this nature are only relatively correct, and must be performed under *exactly* similar circumstances, to furnish even correct comparative results. In the examination of soils, for instance, not only must the heat employed be the same, but the duration of the drying, as well as the method of saturating the air in the large bottle, must also be the same; in fact, the whole process in each case must be as similar as careful manipulation can possibly make them.

ABSORBENTS (IN PHARMACY.) Substances that remove acidity in the stomach and bowels.

List. Magnesia and carbonate of magnesia, prepared chalk, and the carbonates and bicarbonates of soda, potassa, and ammonia, are the principal medicines of this class. The first three are called earthy, and the others alkaline absorbents.

Prop., &c. They neutralize acidity, and frequently possess the power of stopping diarrhœa, (especially chalk,) and relieving heartburn and dyspepsia, particularly when the latter depends on the presence of acidity in the primæ viæ. *Dose.* One teaspoonful of either of the powders (except the last) in a cup of water, forms an excellent antacid draught. The dose of ammonia is 10 to 15 grains.

Remarks. Prepared chalk is most suitable to diarrhœa; potash, soda, or magnesia, to heartburn and dyspepsia; and ammonia, when nervous or hysterical affections are present. The latter, besides being absorbent, is stimulant and diaphoretic, and, in large doses, emetic.

ABSORPTION (IN AGRICULTURE.) The power possessed by soils of absorbing moisture.

Remarks. The more a soil is divided by labor and vegetation, the greater is its absorbent power. and consequently its fertility. The latter chiefly depends on its capacity for imbibing moisture, and may be illustrated by reference to recent and disintegrated lava. (Leslie.) The finely divided state, most penetrable by the delicate fibres of plants, appears to derive its superior power of acting on atmospheric vapor from the augmentation of its surface and the multiplication of its points of contact. (Ure.) This method of increasing the fertility of a soil is well known to scientific farmers, and seldom neglected by them. (Loudon.) The method of ascertaining the absorbent power of soils, is described under ABSORBENT IN CHEMISTRY, to which the reader is referred. That soil must be regarded as the most fertile, which possesses this power in the greatest degree. Garden-mould has the highest absorbent power of any mineral substance. (Leslie.)

ACCIDENTS. *Syn.* CASUALTIES. The reader is referred to the separate articles DROWNING, FIRES, &c. &c., for the best means of either preventing or meeting accidents. The following remarks are, however, so valuable, that they deserve general attention, being equally applicable to every description of casualty and misfortune.

"There is no situation or condition in human life that is not liable to a great variety of serious accidents, against which it is not always possible to guard by the greatest care and foresight. It is of the utmost importance, therefore, to remember that in every accident, one of the greatest and most powerful assistants in remedying it, is *presence of mind.* For want of this desirable self-possession, many a person has lost his life, and the mischiefs arising from unforeseen accidents have become irretrievable. If the mind be overwhelmed by fear, or astounded by alarm, it is utterly impossible that deliberate measures can be taken to secure either our own safety or the safety of those who happen to be about us, and in the same predicament with ourselves. We repeat, therefore, that it is a proof of the truest wisdom to cultivate, and endeavor to preserve as much as possible, in all extraordinary and unexpected situations, either of body or mind, or both, that *chief requisite* in every accident, for acting with coolness, judgment, and effect—*presence of mind.*"

ACERIC ACID. *Syn.* MAPLE ACID. An acid discovered by Scherer in the milky sap of the acer campestre or common maple tree, where it exists in combination with lime.

Prep. Place the juice of the maple in a warm situation for about a fortnight, that it may ferment and lose its acidity; then filter and add a solution of acetate of lead to the clear liquor, separate the precipitate on a filter, and wash it with *very cold water.* Then pour a large quantity of boiling wa-

ter on the filter, and receive it in glass vessels. On cooling, brilliant crystals of acerate of lead will be deposited. After washing the latter with cold water, reduce them to fine powder and suspend it in hot water in a tall glass jar, then pass sulphureted hydrogen gas through the liquid, until all the lead is thrown down; filter, boil for a few minutes to expel the adhering sulphurous gas, then gently evaporate and crystallize.

Prop. These resemble the malic acid. With the bases it forms salts called acerates.

Remarks. From the recent researches of Gmelin and others, it appears probable that the aceric and malic acids are the same, and consequently their salts must be also similar.

ACETAL. *Syn.* OXYGEN ETHER. A fluid discovered by Dobeireiner, and by him called oxygen ether.

Prep. Pour alcohol, to the depth of one inch, into a tall wide-mouthed glass bottle, and suspend three or four watch-glasses or capsules containing platinum powder, to the depth of two lines, close to the surface of the spirit. Moisten the powder with water, and place the apparatus in a warm situation for some months. Acetal, aldehyde, and acetic acid and ether will be formed. The liquor must be then neutralized by adding chalk, and carefully distilled. The product treated with powdered chloride of calcium, until the latter is no longer moistened, decanted, and redistilled, yields pure acetal, as soon as the boiling point reaches 202° Fahr. (Liebig.)

Prop. Liquid, colorless, resembles alcohol, smells somewhat like the Hungary wines; boils at 204° F.; miscible with alcohol; decomposed by strong alkalis and acids. Probably a compound of aldehyde and oxide of ethule. (Liebig.)

ACETATE. *Syn.* ACETAS (*Lat.*); ACETATE (*Fr.*); ESSIGSAURE (*Germ.*) A salt formed by the union of the acetic acid with an alkali, earth, or metallic oxide.

Prop. The majority of the acetates are very soluble in water, and by destructive distillation either yield acetone and water, or acetone and acetic acid. The aqueous solutions of the alkaline acetates turn mouldy and are decomposed by keeping. Care should therefore be taken to dissolve no more at once than is wanted for immediate use.

Prep. Most of the acetates may be formed by direct solution of the hydrate or oxide of the base in the diluted acid, or by double decomposition.

Use. Some of the acetates are employed in medicine, and others are used extensively in the arts.

Tests. The acetates are characterized by the following properties, by which they may be easily detected:—1. The fumes of acetic acid evolved on the addition of sulphuric acid. 2. Striking a deep red when added to solutions of the sesqui-salts of iron. 3. The white lamellar and pearly precipitates they produce with the nitrates of mercury and silver. 4. The production of acetone by exposure to a dull red heat in close vessels.

ACETIC ACID. *Syn.* ACETOUS ACID. ACETYLIC ACID. GLACIAL ACETIC ACID. RADICAL VINEGAR. CONCENTRATED VINEGAR. PURE PYROLIGNEOUS ACID. ACIDUM ACETICUM, P. L. 1836. ACIDUM ACETICUM FORTIUS, P. L. 1824. ACIDUM ACETOSUM, P. L. 1788. ACID ACETIQUE (*Fr.*) ESSIGSAURE (*Ger.*) ACIDO ACETICO (*Ital.*) AZYNZUUR, (*Dut.*) The pure sour principle contained in vinegar, where it exists in a dilute state, and usually in combination with mucilage, sugar, coloring matter, and extractive.

Hist. Acetic acid, in the shape of vinegar, appears to have been known even to remote antiquity. It is mentioned by Moses, nearly 1500 years before the birth of Christ, (Numb. vi. 3,) and was extensively used by the Israelites, as well as by the Greeks and Romans. Hippocrates employed it medicinally, and, according to Livy, Hannibal the Carthaginian general is fabled to have softened the rocks of the Alps by fire and vinegar. Geber purified common vinegar by distillation, and Stahl, at the commencement of the eighteenth century, obtained concentrated acetic acid by decomposing the acetates by oil of vitriol. At the present day acetic acid or vinegar is employed either as an antiseptic, a condiment, or a medicine, in every portion of the civilized world.

Sources. It is found ready formed in several products of the vegetable kingdom, and is generated by the fermentation of saccharine fluids, and the destructive distillation of wood, and other vegetable matter. By the latter process it is procured in combination with empyreumatic matter. (See PYROLIGNEOUS ACID.) Vauquelin found the acetates of potash and lime in elm sap, and Morin detected acetate of ammonia in the juice of the areca catechu. Gmelin says acetic acid has been found in some mineral waters, and Geiger states the same respecting the acetate of potassa. The sambucus nigra, the rhus typhinus, and the phœnix dactalifera contain a large quantity of vinegar.

Var. The acetic acid of commerce is obtained from vinegar, of which there exist four varieties, usually named after the materials from which they are procured, viz.: 1, ***Malt Vinegar;*** 2, ***Wine Vinegar;*** 3, ***Sugar Vinegar;*** 4, ***Wood Vinegar.*** (See VINEGAR.) The first three are formed by the acetous fermentation, which converts the alcohol of the wine, beer, or fermented sugar into acetic acid, by the absorption of oxygen; the latter, by the destructive distillation of wood in iron retorts. By a proper process of purification, each of them may be made to yield an equally pure and concentrated acid. (See ACETIFICATION.)

Prep. In the present article I shall confine myself to the pure acetic acid of the chemist, reserving the consideration of vinegar and pyroligneous acid for separate articles.

There are three different processes employed for the manufacture of pure concentrated acetic acid, viz.: I. *The decomposition of a dry acetate by oil of vitriol;* II. *The decomposition of the acetate of copper or lead by dry distillation;* and, III. *The decomposition of the acetate of lead by sulphate of iron or soda, in the dry way.* I shall describe each, as well as some others less frequently adopted.

I. *By decomposing the acetates by sulphuric acid.*

a. By decomposing the acetate of soda.

1. (*Acidum aceticum, P. L.*) *Ing.* Acetate of soda lb. ij. sulphuric acid ℥ix. water f℥ix. *Proc.* Mix the acid with the water and pour it on the

acetate, previously put into a glass retort, then distil in a sand-bath, taking care not to augment the heat towards the end of the process.

Remarks. The proportions in this process are nearly equal to one equivalent of each of the ingredients, and the result is 51 parts of real acetic acid, and 114·5 parts of water, or 165·5 parts of acetic acid of 30·8% or sp. gr. 1·048 for every equivalent, or 137 parts of crystallized acetate of soda employed, being within 1½% of the estimated product. 100 gr. of this acid exactly saturate 87 gr. of crystallized carbonate of soda. 15 parts added to 85 parts of distilled water is equal in strength to the distilled vinegar of the London Pharmacopœia, or, under common circumstances, 1 part of acid to 7 parts of water is sufficiently accurate.

Prop. The acetic acid P. L. crystallizes at 28° F., and even at 45° if a crystal of acid be dropped into it; melts again under 60°; crystallizes beautifully under a pressure of 1100 atmospheres. (Phil. Trans. 1826.) Is not strong enough to dissolve camphor, resin, or essential oils, in any quantity.

2. (*Pure glacial acid. Liebig's Process.*) *Ing.* Three parts of acetate of soda, thoroughly dried and finely powdered; 9·7 parts of pure sulphuric acid. *Proc.* Pour the acid on the powder, previously put into a capacious retort. A sufficient heat will be developed by the reaction of the ingredients to cause ⅓ of the acetic acid to pass over without a fire; heat must be then applied, until the mass in the retort becomes quite liquid. Rectify the product, when two parts of pure acid will be obtained, containing only 20 per cent. of water. The latter portion which comes over, exposed in a close vessel to a temperature below 40° F., deposites crystals of hydrated acetic acid. The weaker, or liquid portion, being poured off, the crystals may be again melted and crystallized by cooling. The crystals of the last operation, separated from the liquid, are perfectly pure.

b. By decomposing the acetate of potassa by sulphuric acid.

1. (*Process of the Dub. Ph.*) *Ing.* 52 parts of sulphuric acid; 100 parts of acetate of potassa. *Proc.* Similar to that of the London College; carefully distil to dryness. *Prod.* 50 to 51 parts of liquid acid of 1·074. (P. D.)

2. *Ing.* 2 parts of fused and powdered acetate of potassa; 1 part of strongest oil of vitriol. *Proc.* Similar to the above. To remove a slight contamination of sulphurous acid, it may be redrawn, putting a little dried acetate of lead into the retort.

c. By decomposing acetate of lead by sulphuric acid.

1. (*Process of the Ed. Ph.*) *Ing.* Acetate of lead, fused, and in fine powder, ℥vj, pure strong sulphuric acid, f ʒixss. *Proc.* Heat the dried and powdered acetate of lead to 320°, in a porcelain basin, placed in a bath of oil or fusible metal, and continue stirring until the powder ceases to concrete; it must then be weighed, mixed with the acid, and distilled to dryness, at a heat of 320°. Agitate the product with 1 or 2 gr. of oxide of lead, decant the clear portion, and re-distil.

Prop. The sp. gr. of this acid is 1·065. (P. E.) containing, by Mohr's table, 98·5 p. c. of glacial acid.

2. *Ing.* 4 parts of thoroughly dried acetate of lead, in powder; 1 part of the strongest oil of vitriol. *Proc.* Distil to dryness.

Remarks. The above yields a very strong acid, nearly equal to that prepared by the Ed. formula. The quality and quantity of the product are improved if a little peroxide of manganese be put into the retort before distilling. (Baup.) Liebig recommends the proportions to be 3 parts of the acetate to 8 parts of the acid. Dollfuss's concentrated acetic acid was prepared by a similar process, by drawing over 7 oz. of acid from a mixture of 12 oz. of sugar of lead with 6 oz. of oil of vitriol.

II. *By submitting the acetate of copper or lead to dry distillation.* Acetic acid, thus prepared, has been called *spirit of verdigris; esprit de Venus; spiritus veneris, &c.*

a. (*From binacetate of copper, or distilled verdigris.*) *Proc.* Carefully dry the binacetate by a very gentle heat, then introduce it into a stoneware retort, the bottom of which has been previously coated with a mixture of fire clay and horsedung, to render it more capable of standing the heat. It must then be placed in a suitable furnace, and connected by an adopter tube, with 3 or 4 double tubulated globes, the last of which must be furnished with a vertical tubulature, to which a double Welter's safety tube should be connected, the other end being immersed in a basin half filled with distilled vinegar, while the funnel portion communicates with the atmosphere. Each globe is placed in a basin of water, which is kept cool by a stream continually passing through it; the upper portion is also covered with cloths, which are kept wetted with cold water. The distillation is not commenced until 15 or 20 hours after the apparatus is luted together, to allow the luting time to dry and harden. Fire must then be applied, and so regulated that the drops follow each

ether with considerable rapidity from the end of the adopter tube at the same time that the bubbles of air succeed each other, in no inconvenient quantity, from the other end of the apparatus. Should the process proceed too rapidly, the fire should be damped. The operation is continued, and the fire gradually increased until vapor ceases to come over, which is known by the globes cooling, notwithstanding the greater heat of the furnace. The operation is now concluded, and the fire may be allowed to expire. When the whole has cooled, the acid must be collected and rectified in glass vessels before it is fit for sale. The rectifying apparatus may be similarly arranged to the above, with the exception of the whole being formed of glass. The operation must now be very carefully conducted and discontinued before barely the whole of the acid has distilled over, as the last portion is apt to injure the flavor and color. The foregoing diagram represents the form of the apparatus usually employed in this manufacture.

Remarks. This process is similar to that of P. L. of 1787. The acid obtained is nearly equal to half the weight of the verdigris employed. The strongest acid is found in the third receiver, and the weakest in the first, that of the second being intermediate between the two. It is always accompanied by a slight odor of fragrant pyroacetic spirit, for which reason it has generally received the preference for making aromatic vinegar and perfumery. I am informed by a friend that good binacetate of copper will yield by careful management full half its weight of an acid of the sp. gr. 1·050. It dissolves camphor, resins, and essential oils with facility. This is one of the oldest methods of procuring glacial acetic acid, and still continues to be preferred for many purposes.

Caution. The cupreous residuum of the distillation is pyrophoric, and frequently inflames as soon as it is exposed to the air. It consists of metallic copper in a state of minute division along with a little charcoal.

b. (*From acetate of lead.*) Instead of acetate of copper use dried acetate of lead, and proceed as in the last process, taking especial care to avoid overfiring, as the quantity obtained is thereby lessened, while the quality is also inferior.

III. *By acting on a mixture of an acetate and sulphate by heat.*

a. Ing. 2 parts of gently-calcined sulphate of iron; 5 parts of dried acetate of lead. *Proc.* Mix them together in fine powder, and cautiously distil into a large and well-cooled receiver.

Remarks. This is a good and economical process. Badollier's strong acetous acid was made in this way from 1 lb of green vitriol and 10 oz. of sugar of lead.

b. Ing. Sulphate of potassa 12 oz.; oil of vitriol 6 oz.; water 18 oz.; acetate of soda 9 oz. (dried;) oxide of manganese ½ oz. *Proc.* Dissolve the sulphate in the acid and water, evaporate to dryness, then mix it with the acetate of soda and manganese, and distil from a glass retort in a sand-bath. The product has been called Lowitz's acetic acid.

Other methods of making acetic acid, either not generally adopted, or but partially known.

I. *Elegant method of making pure acetic acid.* (From the German.) *Proc.* Take a long glass case and arrange shelves in it, a few inches apart, one above another, on which place small flat dishes of earthenware or wood; then fill these dishes with alcohol, and suspend over each a portion of the black powder of platina, (see Platinum;) hang strips of porous paper in the case, with their bottom edges immersed in the spirit to promote evaporation. Set the apparatus in a light place at a temperature of from 68° to 86° F., for which purpose the sunshine will be found convenient. In a short time the formation of vinegar will commence, and the condensed acid vapors will be seen trickling down the sides of the glass, and collecting at the bottom. We shall find that during this process, produced by the mutual action of the platina and the vapor of alcohol, there will be an increase of temperature, which will continue till all the oxygen contained in the air enclosed in the case is consumed, when the acetification will stop; the case must be then opened for a short time to admit of a fresh supply of air, when the operation will recommence.

Prod. A case of 12 cubic feet contents, with 7 or 8 oz. of platina powder, will produce 1⅛ lb. of absolute acetic acid from 1 lb. of absolute alcohol; and if we reckon the product at the commercial strength of vinegar, the increase will of course be very great. From 25 lb. of platina powder and 300 lb. of alcohol may be produced daily nearly 350 lb. of *pure acid.* It is proper to state that the platina powder does not *waste*, and that the most *inferior* spirit may be employed.

Remarks. The revenue laws of this country unfortunately forbid the adoption of this *beautiful* process, but there is no statute that prevents any individual employing it on the small scale for private consumption. In Germany, vinegar is manufactured on this plan, and from the price of crude alcohol, it must prove very profitable. In the United States of America, where alcohol may be purchased for less than a dollar a gallon, as well as in other parts where spirit is equally cheap, this process will no doubt ultimately prove to be the *cheapest source of pure acetic acid.*

II. *An excellent acetic acid* of considerable strength may be made by soaking perfectly dry charcoal in common vinegar, and then subjecting it to distillation. The water comes over first, and on increasing the heat, the acid follows. Vinegar-bottoms will answer for this purpose.

III. If vinegar or dilute acetic acid be exposed to the air in very cold weather, or to freezing mixtures, the water will separate in the form of ice, and the strong acetic acid may be obtained by draining it into suitable glass vessels, observing to do so at a temperature sufficiently low to keep the water solid.

IV. *An acetic acid sufficiently strong for all ordinary purposes* may be obtained without distillation, by pouring 60 parts of strong sulphuric acid, diluted with 5 parts of water, on 100 parts of well-dried acetate of lime, digesting with occasional agitation in a close vessel, decanting the clear liquid and straining the remainder.

General Commentary. The preceding pages present a brief synopsis of the manufacture of pure acetic acid. On the large scale it is principally manufactured from acetate of soda, which yields a sufficiently strong and pure acid for commercial purposes, without the trouble of rectification. In

this process, shallow copper vessels formed without rivets or solder in those parts exposed to the action of the acid, are employed for the purpose of the distillation. A coil of *drawn* copper pipe, heated by steam, having a pressure of 30 to 35 lbs. to the inch, traverses the bottom of the apparatus. The refrigeratory consists of well-cooled earthenware vessels, and the adopter or pipe connecting the still with the receivers, is also of the same materials. *Stills* of earthenware are also frequently employed, and even worms and condensers of silver are sometimes used. The principal supply of crude acetate of soda at the present time is obtained from America, Norway, and Sweden. This is purified by the chemist and sent to the distiller, who, after extracting the acetic acid, returns the resulting sulphate of soda to the chemist, who employs it in the decomposition of acetate of lime. This ingenious method of mutual assistance and application of chemical science offers some explanation of the low price at which this article may now be purchased. I have seen a very pure acetic acid of sp. gr. 1·050 lately bought in quantity at the *extraordinary low price* of 5½d. per pound. In preparing the acid on the small scale, glass retorts are usually directed to be used, but glass alembics are much more convenient and safe, as the product is less likely to be contaminated by the spirting of the ingredients, or the liquor boiling over the brim of the vessel. In preparing the pure acid, care should be taken that the acetate of soda does not contain common salt, as the carbonate of soda, prepared by calcination, and frequently used to form the acetate, is generally contaminated with it, and yields up its muriatic acid during the process of distillation, thus vitiating the product. The formula of the London College produces a beautiful acid of 1·048; that of the Dublin College another acid of 1·074; and that of the Edinburgh a still stronger acid; but the process of the latter is so unnecessarily minute and complicated, that it is never employed except for experiments. In all these methods the product becomes more concentrated in proportion to the dryness of the materials and the strength of the oil of vitriol used. The process of Liebig is unexceptionable, and yields a very strong and pure acid by the first distillation, which may be afterwards further concentrated if required, as is directed in that formula. Acid containing 20% of water, yields a good deal of its superfluous water to dry sulphate of soda, by standing over it. (Liebig.)

In all these processes the acetic acid exists ready formed in the acetate, and is set free by the superior affinity of the sulphuric acid for the base; and from its volatility, passes over into the receiver on the application of heat; when, being again cooled, it is condensed. In the distillation of verdigris, heat may be said to perform a similar part to that of the acid. (See ACETIFICATION and VINEGAR.)

Prop. Pure acetic acid (*glacial*) is liquid above 62°, but below that temperature forms brilliant, colorless, transparent scales and tabular crystals. In the liquid state its sp. gr. is 1·063. It possesses a powerful odor, and acid taste, dissolves camphor and resins, and mixes with alcohol, ether, essential oils, and water. In its pure state it is a corrosive and an acrid poison. It unites with the basis, forming salts called acetates. It should be kept in stoppered glass bottles.

Uses. In the arts. (Dilute under the form of vinegar.) As an antiseptic in pickling and preserving animal and vegetable food, and anatomical preparations; in dyeing and calico printing the manufacture of tinctures and other pharmaceutical preparations. *As a medicine.* A little added to water forms a useful febrile drink, employed also for scurvy, and as a palliative in phthisis. Added to clysters, it has been used in obstinate constipation; mixed with honey it forms a common gargle in ulcerated sore-throat; a few drops mixed with water make an excellent collyrium for chronic ophthalmia, and for removing lime-dust from the eye; in sprains and bruises it forms a useful fomentation. Strong acetic acid (P. L.) applied by means of a piece of rag tied to the end of a small stick, is a certain cure for ringworm or scaldhead—one or two applications generally effect a cure; as a caustic, it is used to remove warts and corns; a piece of lint or blotting-paper wetted with it and applied to the skin, and evaporation prevented by a piece of strapping, forms a common extemporaneous blister; it was once employed as a disinfectant, but is now only used as a fumigation, to remove the unpleasant smell of the sick room or crowded assemblies. *As a condiment*, it promotes the appetite and digestion, but its habitual use is said to produce emaciation. It also forms a popular refreshing scent in faintings, asphyxia, and nervous headache; and is also frequently used as a rubefacient, astringent, and local stimulant. The *strong acid* taken internally acts, however, as a violent poison, dissolving the animal tissues, and by destroying the organization, causing death. Orfila has recorded a fatal case arising even from its application to the surface of the body. *Dose, &c.* As a refrigerant, water soured with acetic acid or vinegar may be taken ad libitum. In enemas, 1 to 2 oz. of distilled vinegar is the proper quantity; for a lotion, 3 oz. of the latter to 5 or 6 oz. of water; and for a collyrium, 1 oz. of ditto to 1 pint of distilled water.

Purity. Acetic acid or vinegar is frequently adulterated with oil of vitriol, nitric or muriatic acid, as well as various other acrid substances, for the purpose of giving it a spurious acidity. It also frequently contains copper, which it derives from the vessels in which it has been kept or measured. The following table, which I have arranged for the purpose, exhibits an easy method of ascertaining its purity.

In addition to this, it may be remarked that sulphurous acid may be recognised by yielding a white precipitate on the addition of a small quantity of peroxide of lead, or by drawing the fumes into the lungs; acrid vegetable matter, as pepper, capsicum, horseradish, &c., by neutralizing the acid with an alkali, when it may be easily discovered by tasting.

Excise Law. Vinegar is allowed by law to contain $\frac{1}{1000}$ part by weight of sulphuric acid, it will therefore give a trifling precipitate with the tests mentioned in the table, but this will in no case exceed the 1·15 gr. (when dried and weighed) for a fluid ounce. The manufacture of acetic acid of any kind comes under the excise laws, and requires a license, which costs 100*l.* (Collyer.) The duty is at the rate of 2d. on every gallon of proof or No. 24 vinegar, until the strength reaches 35

o. p. or over proof, or equal to an acid of 40%, when it is charged in a different manner. (See ACETIMETRY.)

Tests. These are the same as for the acetates. *Estim.* (See ACETIMETRY.)

Behavior of Tests with Vinegar.

Names of Tests.	Acetic Acid quite pure.	Acetic Acid containing Oil of Vitriol.	Acetic Acid containing Nitric Acid.	Acetic Acid containing Muriatic Acid.	Acetic Acid containing Metals.
Solution of chloride of barium, nitrate of baryta, or chloride of calcium	...	White precipitate insoluble in nitric acid.			
Powdered chalk (short of saturation)	...	Ditto.			
Muriatic acid, added to the sample previously boiled with a little silver-leaf	...	...	White curdy precipitate, soluble in ammonia.		
Dilute solution of indigo (boiled)	...	...	Decolored.		
Gold-leaf wetted with muriatic acid, and digested with heat in a watch-glass	...	...	Partially dissolved.		
Gold-leaf moistened with nitric acid ...	...	...	...	Partially dissolved.	
Dilute solution of nitrate of silver... ...	...	Pearly-white precipitate.	...	Curdy-white precipitate, soluble in ammonia.	
Weak solution of iodide of potassium	...	...	...	...	Yellow precipitate, if lead be present.
Solution of acetate of lead	...	Whitish precipitate.	...	Turbidness.	
Sulphureted hydrogen gas or water	...	...	...	...	Black or dark-colored precipitate. (If this be dissolved in nitric acid, and ammonia added, it will give a blue color if copper be present.

ACETIFICATION. The oxidation of alcohol in the process of making vinegar. To be capable of acetification or conversion into vinegar it is necessary that the liquid should contain alcohol in some state or other, or some substance, as sugar, which, by the process of fermentation, is capable of producing it. The presence of a ferment or vegetable matter, and a temperature between 70° and 100° F., facilitates the operation. In the conversion of wines, beer, wort, &c. into vinegar, the sugar is first transformed by fermentation into alcohol, and in this state becomes oxidized or acidified by the absorption of atmospheric oxygen. Manufacturers should always remember that such is the true nature of this process. (See ACIDS, ACETIC ACID, and PYROLIGNEOUS, and VINEGAR.)

ACETIMETER. *Syn.* ACETOMETER. An instrument or apparatus for ascertaining the strength of acetic acid. (See the next article.)

ACETIMETRY. *Syn.* ACETOMETRY. The art or process of determining the strength of vinegar or acetic acid. Various methods have been proposed for this purpose, among which may be mentioned the following:

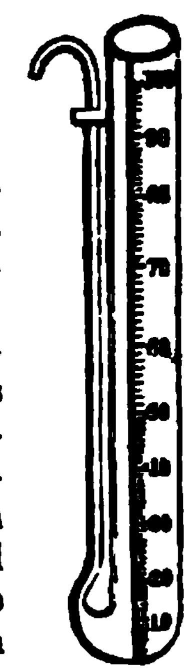
I. (*The plan adopted by the Excise.*) Hydrate of lime is added gradually to a sample of the vinegar, until it is *saturated*, and the sp. gr. of the resulting clear solution of acetate of lime is taken by the acetometer, invented by Messrs. J. and P Taylor. This instrument in construction resembles the common hydrometer, and stands at the mark on the stem called proof in a solution containing 5% of real acid, which is the strength of No. 24 vinegar, or an acid which will saturate exactly 14½ grains of crystallized carbonate of soda When the vinegar is stronger than proof, the instrument must be loaded with one or more of the small weights which are supplied with it, each of

which will indicate an additional 5§ up to 35§, which is the greatest strength at which the duty is levied by the gallon. To ascertain the per centage of real acid, 5§ must therefore be added to the number indicated by the acetometer. Thus: without being loaded, the instrument, on floating to a given mark, indicates a proof vinegar or one of 5§; with *one* weight, a vinegar of 10§; with *two* weights, 15§; with *three* weights, 20§, &c., &c. The reason of this is, that the starting point, or proof, is an acid of 5§. In the technical language of trade, each 5§ is called a vinegar. Thus: acid of 10§ is said to contain *two* vinegars; one of 15§, *three* vinegars, &c. A more common method is, however, to speak of the degrees of the acetometer as proof or overproof. Thus: No. 24 vinegar is said to be proof; one measuring 5 acetometer degrees—5 overproof or o. p.; one 10 degrees—10 o. p., &c. In malt and wine vinegars, which usually contain gluten or mucilage, this method is not strictly accurate, as these substances alter the specific gravity. A small weight marked M is supplied by Mr. Bate with the acetometers made by him, and is used in trying such vinegar.

Remarks. This plan, though sufficiently correct for commercial purposes, is liable to a small error, especially in vinegar containing much vegetable matter. If it be pure or very nearly so, the decimal fraction of the sp. gr. will be doubled by conversion into acetate of lime. Thus: 1·0085 in vinegar becomes 1·0170 when converted into a solution of acetate of lime. In malt vinegar, however, 0·005 may fairly be deducted from its sp. gr. as produced by the presence of mucilage and gluten. The quantity of foreign matter present in vinegar, may thus be approximatively ascertained, by deducting the decimal of the sp. gr. of the solution of acetate of lime, from double that of the decimal part of the sp. gr. of the vinegar. Thus: I find the sp. gr. of a sample of vinegar to be 1·014, and after saturating it with hydrate of lime, I again try it and find it to be 1·023, what is the sp. gr. of the *pure* vinegar, and what is due to foreign matter—

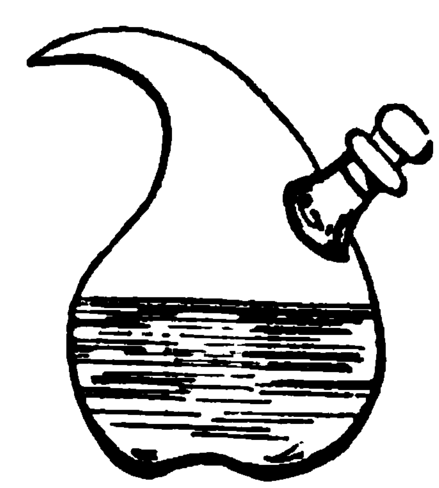
Decimal of sp. gr. of vinegar, doubled	·028
Decimal of sp. gr. of solution of acetate of lime	·023
Quantity of foreign matter equal to the difference	·005
Specific gravity of vinegar	1·014
Deduct sp. gr. due to foreign matter .	·005
Sp. gr. of a solution of acetic acid or pure vinegar of equal strength to sample	1.009

II. Dissolve 200 grains of pure crystallized bicarbonate of potash in a little water, and then add enough water to make it up to exactly 1000 parts by measure; as for instance, 1000 minims. A solution is thus formed, which, when added to a sample containing 100 measures of acetic acid or vinegar, until the latter be saturated, will indicate the exact amount of real acetic acid present. The test liquor should be made and measured in a long glass tube, capable of holding the whole 1000 measures, and graduated into 100 parts, every one of which will represent 1§ of dry acid. A convenient instrument for this purpose, is the *pouret* of Gay Lussac, which consists of a double tube of the shape of the following figure.



Remarks. Any other method of measuring or ascertaining the exact quantity of test liquor employed, may be used, as convenience or circumstances may suggest; but however this is done, it is necessary to do it in such a manner as to ensure the greatest accuracy.

III. Dissolve 200 grains of crystallized bicarbonate of potassa in 800 grains of distilled water, contained in a suitable shaped bottle, previously carefully weighed; when dissolved, weigh it again, and see that it is exactly equal to 1000 grs. This test liquor, like the last, is used to neutralize the acid in the sample for examination, but in this case the quantity must be 100 grs. instead of 100 measures. Every grain of the test liquor consumed will, therefore, indicate 1 tenth of a grain of real acetic acid, and every 10 grs. will be equal to 1§. A very convenient shaped bottle for this purpose is that known as Schuster's Alkalimeter, which consists of a very light stoppered glass bottle, having a neck drawn out to the one side, and furnished with a very fine orifice, which admits of the liquid being poured



out in small quantities with greater ease, and without the risk of an accident. The weight of the bottle and solution, after the process of neutralizing the acid of the sample, deducted from its previous weight, gives the exact weight of the test liquor consumed, and consequently the quantity of acetic acid that has been saturated by it.

Remarks. This method admits of great accuracy, and is preferable to the previous process, (No. II,) as it is much easier to weigh than to measure correctly, especially when the quantity is small.

IV. Instead of bicarbonate of potash, in Nos. II and III, either of the following salts may be used.

104 grs. dry carbonate of soda.
135 " " carbonate of potash.
283 " crystallized carbonate of soda.

Remarks. The dry carbonates of potassa and soda should be prepared by submitting the crystallized carbonate to a dull red heat in a crucible, when, after cooling, the proper quantity may be weighed.

V. By taking the specific gravity of the sample, (see Specific Gravity,) and seeking it in the following Tables, the per centage of acid may be ascertained sufficiently correct for most purposes.

TABLE I. The following Table is given by Messrs. TAYLOR, as the basis of their Acetometer.

Revenue Proof Acid, called by the manufacturer No. 24.

sp. gr.		
1·0085	contains real or anhydrous acid in 100,	5
1·0170	" "	10
1·0257	" "	15
1·0320	" "	20
1·0470	" "	30
1·0580	" "	40

TABLE II. The following Table, from the Pharm. Central Blatt für 1839, drawn up by M. MOHR, exhibits the sp. gr. of pure Acetic Acid of almost every strength.

Per cent. of Glacial Acid, (C. 4, H. 3, O. 3+Aq.)	Sp.Gr.	Per cent. of Glacial Acid, (C. 4, H. 3, O. 3+Aq.)	Sp.Gr.	Per cent. of Glacial Acid, (C. 4, H. 3, O. 3+Aq.)	Sp.Gr.

Remarks. Table I is adapted to commercial vinegar, and is sufficiently accurate for all common purposes. Table II is intended for pure acetic acid. It will be seen that above a certain per centage, the specific gravity retrogrades; it is, therefore, better in trying very strong acid, to dilute it first with a given weight of distilled water, and to allow for it afterwards. The weight of glacial acetic acid, multiplied by ·8512, gives the weight of dry acid which it contains, and anhydrous acid, multiplied by 1·1748, will give a number representing an equivalent weight of glacial acid.

Caution. As a spurious acidity is frequently given to vinegar by adding other acids to it, which would thus give it a false appearance of strength, it is, therefore, better first to ascertain whether it be adulterated. (See ACETIC ACID.) The most correct, and, in many respects, the easiest method of acetimetry, is No. III or IV. The acetic acid of the L. P. has a sp. gr. of 1·048, and contains 30·8% of dry acid.* That of the Dublin College is 1·074, and that of the Edinburgh College 1·065.† (See SPECIFIC GRAVITY, and ACIDIMETRY.)

ACETULE. The hypothetical radical of the acetule series; neither itself nor oxide has been obtained alone. Its *hydrated oxide* is *aldehyde.* The *chloride of acetule* is formed by the lengthened exposure of chloride of ethule to the action of chlorine and light. The *oxychloride*, by saturating anhydrous ether with perfectly dry chlorine gas, exposing to external cold, and afterwards to a gentle heat. Both this and the preceding are transparent colorless fluids. *Suboxychloride of acetule* is a gas formed by heating the last article in contact with potassium. *Oxysulphuret of acetule* is made by passing sulphureted hydrogen gas through the oxychloride, until an oily liquid is formed, which, by exposure, becomes semi-crystalline. This is dissolved in hot alcohol, and is obtained in crystals on its cooling.

Remarks. For a knowledge of the preceding substances we are indebted to the researches of Malaguti and Regnault. The compounds of acetule offer beautiful examples of chemical substitution, but the nature of the presen work will not permit their being enlarged on here.

ACHROMATIC. Free from color, (from the Gr. ἀ, without, and χρωμα, color,) from which also is derived the word

ACHROMATISM. The destruction of the colored rings, which accompany the image of an object seen through a lens or prism.

Causes, &c. Light is not homogeneous, but decomposable into colored rays, either by refraction, absorption, or reflection. The colors of the prismatic spectrum are formed out of a ray of white light, by passing it through a glass prism, and a similar effect is produced if a lens or other refracting media be used instead. It has been observed, that when this production of color takes place, some of the colored portions of the spectra are more bent or refracted than others, and that the refracting or dispersive power varies with the nature of the refracting medium. A beam of light thrown on a simple converging lens, not only suffers refraction at the spherical surface, (called spherical aberration,) but the different colored rays, forming the beam of light, being unequally bent or refracted, diverge from their original course, and, consequently, fall separately instead of together, on the eye or object that receives them. Hence arise the colored rings or halos that surround objects viewed through ordinary glasses This effect is called chromatic aberration by opticians, and forms the greatest impediment to the construction of a *perfect* refracting telescope. It is the object of achromatism to remove this impediment. The subject, theoretically considered, is not less fraught with difficulty than with practical importance, and has engaged the attention of the first mathematicians and artists up to the present time.

* Dr. A. T. Thompson says (p. 819 of his Dispensatory, 10th ed.) "that it contains 30·7% real acid by weight;" yet, on the next page he says, "that of the L. C. contains 37% of real acid and 63% of water."

† In one place in the E. P. it is stated to be 1·065, and in another, 1·0685.

Correction. It has been endeavored to correct the chromatic aberration of lenses, by combining two or more made of different materials, possessing different dispersive powers. Thus the spectrum formed by flint glass, or glass containing lead, is longer than that formed by crown glass, for the same deviation; and when combined, the one tends to diminish the dispersion of the other. On this principle the achromatic object glasses of telescopes are generally formed in this country. A convex lens of crown glass is combined with a weaker concave lens of flint glass, the latter counteracting the dispersion of the former, without materially interfering with its refraction. A still better plan is, to place a concave lens of flint glass between two convex lenses of crown glass.

Remarks. All the larger object glasses lately manufactured are said to consist of only two lenses; the resulting achromatism proving sufficiently exact for all useful purposes. The principal achromatic glasses and telescopes recently made, have been manufactured by Dolland of London, and some of the opticians of Bavaria and Switzerland. The achromatism of prisms depends upon the same principles, and is determined and corrected in the same manner as lenses, but presents less difficulty on account of the spherical aberration of the latter. (See LENSES, TELESCOPE, MICROSCOPE.)

ACIDS. *In common language,* any substance possessing sourness or acidity; *in chemistry,* any electro-negative compound, capable of combining with bases to form salts. Most of the liquid acids possess a sour taste, and redden litmus paper.

Hist. The chemical theory of the acids is still undecided, and the laws which regulate their combinations with the bases, as well as the precise nature of the resulting salts, are involved in considerable obscurity. Lavoisier and the associated French chemists conceived that acidity resulted from the union of a peculiar combustible base, called a radical, with a common principle of acidification, called oxygen. The inaccuracy of this hasty generalization was disproved by Berthollet, who maintained that it was "carrying the limits of analogy too far to presume that all acidity arises from oxygen." The early opinion of Sir H. Davy, after revised and modified by Murray, was, that intimately combined water was the real "acidifying principle." In 1810, however, this celebrated chemist published a series of dissertations in the Philosophical Transactions, which fully overthrew the hypothesis of Lavoisier. It was soon established that both oxygen and hydrogen were capable of producing acids, of which the sulphuric and muriatic acids may be taken as examples. It is now generally acknowledged that no *one* substance or element can be regarded as the general "*acidifying principle.*" The more recent theory of the acids, elaborated out of the researches of Graham, Liebig, Dumas, Clark, Fremy, Thalow, Dulong, Peligot, and others, is affirmed by its supporters, to establish the views first suggested by Sir H. Davy, respecting the chloric and iodic acids and their salts. In this scheme, all the acids are united into one series, and all the salts into another, both being so closely connected, that it is said, "that these two series may be considered as one." The existence of hydrogen in the oxygen acids, in the free or active state, is here deemed an essential part of their constitution, and hence the name of hydracids has been given to them. This principle has been extended to *all* the acids, even the organic. Those acids that contain 1 eq. of hydrogen, are called monobasic; with 2 eq., bibasic; with 3 eq., tribasic, and so on; the general term polybasic, being applied to those which combine with two or more eq. of hydrogen. The muriatic may be taken as the type of the first; the tartaric that of the second; and the citric acid that of the third. This view of the acids presents the advantages of simplicity and unity of classification. In the union of the acids with the bases forming salts, it presumes that the hydrogen of the acid is replaced by the base, it having previously played the part of a base itself. Consequently acids may be viewed as the hydrogen salts of their radicals, and acids and salts, with regard to their constitution, form but one class. "The neutralizing power of an acid depends entirely on the number of eq. of hydrogen replaceable by the bases." (Liebig.) Other hypotheses have arisen respecting the acids, but have possessed little merit and obtained little notoriety.

Class. The acids have been variously classed by different writers, as into *organic* and *inorganic; metallic* and *non-metallic; oxygen acids, hydrogen acids, and acids destitute of either of these elements;* the names being applied according to the kingdom of nature, or class of bodies to which the radical belonged, or after the element which was presumed to be the acidifying principle.

Nomen. The names of the acids end either in *ic* or *ous;* the former being given to that containing the larger portion of the electro-negative element, or oxygen, and the latter to that containing the smaller quantity. As sulphuric acid, an acid of sulphur, containing 3 atoms of oxygen; sulphur*ous* acid, another sulphur acid, containing only 2 atoms of oxygen. When a base forms more than 2 acid compounds with oxygen, the Greek preposition *hypo* is added to that containing the smaller portion, as hyposulphuric and hyposulphurous acids. This system of nomenclature was originally adopted under the idea that *all* acids contained oxygen, but the same terms are now applied, regardless of the acidifying principle, as hydrochloric acid, hydrofluoric acid, &c. The prepositions *per, hyper,* and the syllable *oxy* are also prefixed to the names of acids, when it is intended to denote an *increase* of oxygen, as hypernitrous acid, perchloric acid, oxymuriatic acid, &c.

Cautions. All the strong liquid acids should be kept in glass bottles, furnished with perfectly tight ground-glass stoppers; glass vessels should be used in measuring them, and they should be dispensed in stoppered vials.

ACIDS, OXYGENIZED. These are compounds to which an apparent surcharge of oxygen is given by means of deutoxide of barium. They were first discovered by M. Thernard, and described by him in the Ann. de Chim. et Phys. viii. 306.

Proc. 1. Nitrate of baryta should first be obtained perfectly pure, and, above all, free from iron and manganese. The most certain means of procuring it is to dissolve the nitrate in water, to add to the solution a small excess of baryta water,

to filter and crystallize. 2. The pure nitrate is to be decomposed by heat. This ought not to be done in a common earthenware retort, because it contains too much of the oxides of iron and manganese, but in a perfectly white porcelain retort. Four or five pounds of nitrate of baryta may be decomposed at once, and the process will require about three hours. The baryta thus procured will contain a considerable quantity of silex and alumina; but it will have only very minute traces of manganese and iron, a circumstance of essential importance. 3. The baryta, divided by a knife into pieces as large as the end of the thumb, should then be placed in a luted tube of glass. This tube should be long and large enough to contain from 2¼ to 3½ lbs. It is to be surrounded with fire, and heated to dull redness, and then a current of dry oxygen gas is to be passed through it. However rapid the current, the gas is completely absorbed; so that when it passes by the small tube, which ought to terminate the larger one, it may be concluded that the operation is completed. It is, however, right to continue the current for seven or eight minutes more. Then the tube being nearly cold, the deutoxide, which is of a light gray color, is taken out and preserved in stoppered bottles. When this is moistened it falls to powder, without much increase of temperature. If in this state it be mixed with seven or eight times its weight of water, and a dilute acid be poured in, it dissolves gradually by agitation, without the evolution of any gas. The solution is neutral, or has no action on turnsole or turmeric. When we add to this solution the requisite quantity of sulphuric acid, a copious precipitate of baryta falls, and the filtered liquor is merely water, holding in solution the oxygenized acid, or deutoxide of hydrogen, combined with the acid itself.

ACIDIMETER. An instrument or apparatus wherewith to ascertain the strength of acids. (See Hydrometer.)

ACIDIMETRY. The estimation of the strength of acids.

Memo. This operation must be understood to refer to the relative strengths of the same acids, (viz. quantity of real acid of the same kind contained in the solutions examined,) and not to the comparative strengths of acids of different compositions or names. Theoretically, capacity of saturation is no proof of *strength of affinity*, or *acid power* in *different acids* in opposition to the views propounded by Berthollet. Thus, it takes 50 grs. of chalk, or 54 grs. of dry carbonate of soda to neutralize 37 grs. of real muriatic acid, but the same quantity is enough to neutralize 49 grs. of the strongest oil of vitriol, containing 40 grs. of real acid. It thus appears that a *less* quantity of *muriatic* than *sulphuric acid* is equivalent to any given weight of base, and according to Berthollet's theory, the former should be considered the stronger acid. The reverse is however the case, as oil of vitriol will take lime from its solution in hydrochloric acid. No absolute criterion of the scale of power, among the *different* acids, has as yet been discovered. The present article will be confined to methods of acidimetry applicable to the acids generally, but directions more especially adapted to the principal acids will be found under their particular heads. (See Acetimetry, Muriatic Acid, Sulphuric Acid, &c.)

Acidimetrical Processes. These are founded on the capacity of the acids to saturate the bases.

I. Place a weighed sample, say 100 grs. of the acid to be examined in a glass tube or other suitable vessel, and, if it be a strong acid, it is better to dilute it with six or eight times its weight of pure water, and if solid or crystallized, as citric or tartaric acid, to dissolve it in a like quantity. A weighed portion of dry powdered carbonate of soda or potassa prepared from the crystallized carbonate by exposing it to a red heat, is then *gradually* and *carefully* added, until the acid is saturated, which is known by its ceasing to effervesce, and to redden litmus paper. Great care must be taken not to exceed the quantity necessary for this purpose. After adding each portion of soda the solution should be well stirred up, and as soon as the effervescence becomes languid the greatest caution must be observed in adding fresh portions of the alkali. The proper point is arrived at when the liquid ceases to *redden litmus*, and does not *alter the color* of *turmeric paper;* if it turns the latter *brown*, too much soda has been added, and the operation becomes useless. As soon as the point of saturation or neutralization is arrived at, the remaining carbonate of soda is weighed, and its present deducted from its former weight will give the quantity consumed, every 53½ grs. of which will represent an equivalent of real acid, according to the following table, which I have arranged for the purpose.

Remarks. This method is sufficiently accurate for common purposes, but when greater exactness is required, the following plan is preferable: The reason for the adoption of the carbonate of potassa or soda is, that they have a uniform constitution when prepared in the way described as above. Either of the other articles mentioned in the table may, however, be used instead, if at hand, and known to be pure.

Table representing the quantities of the Carbonates of Soda, Potassa, Lime, Carbonic Acid, and Hydrate of Lime, equivalent to the given weights of some of the Acids, together with the composition of the latter, hydrogen being considered equal to 1.

53½ grs. of dry carbonate of soda,	50½ grs. pure chalk,
143½ „ crystallized ditto,	37½ " of hydrate of lime, (fresh,)
84½ „ bicarbonate of ditto,	44½ " of dry carbonic acid, (when the bicarbonate of potassa or soda is used for testing in the process of Fresenius and Will.)
69½ „ dry carbonate of potassa,	
100½ „ crystallized bicarbonate of ditto,	

are equivalent to

II. Dissolve 100 grs. of the carbonate of soda or potassa, prepared as above, in 700 or 800 measures of boiling water, and when cold make the quantity up to exactly 1000 measures; this forms a test liquor, every 10 measures of which represent 1 gr. of the dry carbonate, and every single measure 1 tenth of a grain. A convenient graduated glass tube for this purpose is Gay Lussac's *pouret*, described under the article ACETIMETRY. This liquid must be applied to neutralize the acid, as described in the last process, and the quantity consumed for that purpose may be read off on the graduated tube.

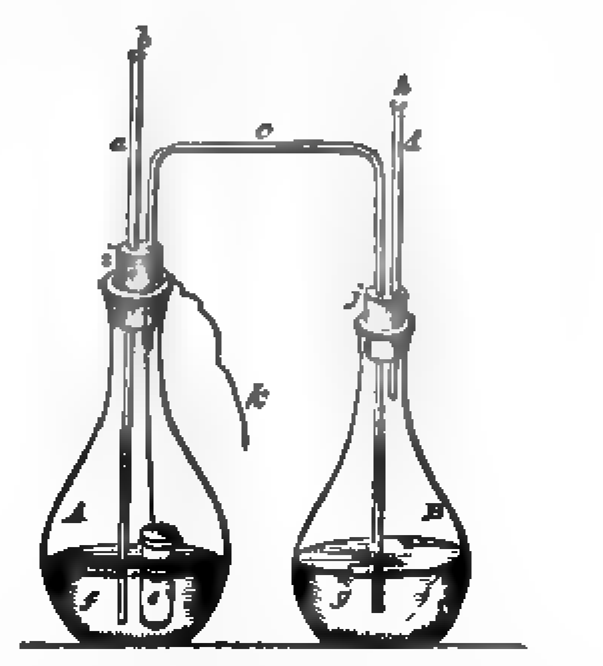
Remarks. This plan allows of the alkali being added with greater ease and in smaller quantities than can possibly be done with a powder. If the graduated portion of the *pouret* be divided into 100 parts, each of them will represent exactly one grain of the carbonate.

III. Dissolve 100 grs. of the dry carbonate of soda or potassa before described in 900 grs. of hot water, and when cold make it up to exactly 1000 grs. This forms a test liquor, capable of being applied with *great accuracy*, every grain of which will represent 1 tenth of a grain of alkali, and every 10 grs. will be equal to 1 gr., from which the real quantity of acid present may be ascertained from the preceding table, and by the simple rule of proportion the per centage may be found.

Remarks. The solution is best made and used in a bottle known as Schuster's Alkalimeter, described under the article ACETIMETRY. The operation is conducted thus: The sample of acid, being accurately weighed, is diluted or dissolved in 6 or 7 parts of water, and the bottle containing the test liquor is then carefully balanced in the scales and the weight noted. The contents of the latter are then added in small and successive portions to the acid until the point of saturation is approached, when great care must be observed lest too much be added. As soon as the exact point of saturation is arrived at, the bottle holding the test solution must be again accurately weighed, when its loss of weight, divided by 10, will give the number of grains of the carbonate consumed.

IV. (*Method of Drs. Will and Fresenius, of Giessen.*) *Explan.* This method depends upon the quantity of carbonic acid gas which a given weight of acid is capable of expelling from the bicarbonate of soda or potassa, which is estimated by the loss of weight in the apparatus, after the gas, rendered perfectly dry by passing through sulphuric acid, has escaped into the air, from which the quantity of acid present in the sample is found by a simple calculation.

Oper. A determinate amount of the acid under examination is accurately weighed into the flask A, fig. p. 22; and if it be a concentrated acid or a solid, it is mixed with or dissolved in 6 or 8 times as much water. The little glass tube *e* is then nearly filled to the brim with pure bicarbonate of soda in powder, and a fine silk thread is tied round the neck of the tube, by means of which it is lowered down into the flask A, so as to remain perpendicularly suspended when the cork is placed in the latter, the cord being held between the cork and the mouth of the flask. The flask B is about half filled with oil of vitriol, and the tubes being ranged in their places, as represented in the engraving, the whole apparatus is accurately weighed, time having been allowed for the mixture of acid and water to cool completely, should it have become hot by mixing. The cork in the flask A is then slightly loosened, so as to allow the little tube containing the bicarbonate of soda to fall into the acid, and is again immediately fixed AIR-TIGHT in its place. The evolution of carbonic acid now commences, and continues until the acid in the flask A is neutralized. When this takes place, which is easily seen by no bubbles being emitted on shaking the apparatus, the flask A is put into hot water, and kept there with occasional agitation until the renewed evolution of gas has completely ceased. The little wax stopper is then taken off the tube *a*, the apparatus taken out of the hot water, wiped dry, and suction applied by means of the mouth to the end of the tube *d*, until the sucked air no longer tastes of carbonic acid. The whole is then allowed to become quite cold, when it is replaced in the balance (the other scale still containing the original weights) and weights added to restore the equilibrium, which will thus give the exact weight of the dry carbonic acid gas that has been expelled from the bicarbonate of soda, by the action of the sample examined, from whence the quantity of *real acid* it contained is deduced by the following calculation:—*Two measures of carbonic acid* bear the same proportion to *one measure of the anhydrous acid* in question, as the amount of the *carbonic acid* expelled, does to the amount sought of *anhydrous acid*. Thus, let us suppose, for instance, we had examined dilute sulphuric acid, and obtained 3 grs. of carbonic acid, the arrangement would be $(22{\cdot}12\times2) : 40 :: 3 : 2{\cdot}72$. The amount of sulphuric acid operated upon, consequently, would contain 2·72 grs. of anhydrous acid. Let us suppose the weight of this amount to have been 15 grs., the sulphuric acid



A, A wide-mouthed flask, capable of holding 2½ to 3 oz. containing sample for trial, *f*.

B, Ditto, capable of holding 1½ to 2 oz., partly filled with oil of vitriol, *g*.

h, Open end of the tube *d*.

k, Silk cord fastened to the tube *e*.

under examination would contain 18·13 *per cent. of real acid;* for 15 : 2·72 :: 100 : 18·13. The quantity of acid in the sample may also be found from the preceding table, where it will be seen that 44¼ grs. of dry carbonic acid are equal to the respective quantities of the different acids, mentioned in the first and second columns, which by the simple rule of three may be converted into the strength per cent. The foregoing engraving is a sketch of the apparatus employed in this operation.

Remarks. This operation, though perhaps *apparently* complicated, is in reality very simple and easy to perform, when once understood. It is not absolutely necessary that the bicarbonate of soda be perfectly pure, so long as it does not contain any neutral carbonate or sesquicarbonate of soda. The absence of these salts is absolutely necessary, for which reason Messrs. Fresenius and Will direct the bicarbonate of commerce to be purified in the following manner:—For this purpose, half a pound to one pound of it is reduced to a uniform powder, and a portion of it first tested with perchloride of mercury; if the result be satisfactory, the powder is put into a glass jar, and covered with the same amount of cold rain water; it is then allowed to stand for twenty-four hours, with frequent stirring; the salt is then placed upon a funnel, the tube of which is stopped with loose cotton, so as to allow the ley to drop off; the salt is then washed several times with small quantities of cold rain water. The bicarbonate of soda, after this operation, is generally pure, and adapted for acidimetrical purposes. It is dried between some sheets of blotting-paper, without the aid of heat, and kept for use in a well-closed glass bottle. Before use, it may be again tested to ascertain its purity. The application of heat after the completion of the operation is indispensable, as, if it were neglected, from 25 to 30 milligrammes less of carbonic acid would be obtained. The bicarbonate of potassa may be used in this method of acidimetry with equal advantage as that of soda, provided it be pure; but in either case it is always proper to use an excess, so as to leave some undecomposed after the operation is concluded. A piece of litmus paper plunged into the liquid in A will not be reddened if the process has been properly managed.

General Commentary. The preceding sketch of the principal methods of acidimetry will, it is hoped, be found sufficiently explicit to be generally understood by workmen in laboratories, and by tradesmen and others to whom it may be an object to be able accurately and expeditiously to test the acids that pass through their hands. The methods Nos. II. and III., and especially the latter, combine the above requisites in an eminent degree, and if a quantity of the test solution of the proper strength be prepared as there described, it may be kept unharmed for any length of time, in a stoppered bottle, and will be always ready for application wherever a good pair of scales or a graduated measure is to be found. The only danger to be dreaded is over-saturation, and this may be avoided by care and attention. A good method is to tint the acid sample with a few drops of litmus, as described under Alkalimetry, when it will assume a reddish shade, which will gradually deepen into purple as the point of saturation is approached, and recover its blue color as soon as this point is arrived at. To see that this point is not passed, a piece of turmeric paper may be dipped into the solution, which will retain its color if neither acid nor alkali predominate, but if the latter be in excess, will become brown, as before described. The ingenious and elegant method of Fresenius and Will, for which the English reader is indebted to Mr. Bullock, though admirable in the hands of a person accustomed to chemical manipulations, appears somewhat difficult to mere *practical* men, and is liable to failure in their hands. The results, however, if the process be properly conducted, are unimpeachable.

In commerce, the strength of acids is frequently reckoned with reference to a standard, termed 100 acidimetric degrees. This is taken from the circumstance that 91 grs. of commercial oil of vitriol, of a sp. gr. of 1·845, exactly saturate 100 grs. of dried carbonate of soda, and hence is said to be of 100 acidimetrical degrees. Any other acid requiring only 35, 50, or any other number of grains of the carbonate to saturate it, would in like manner be termed so many degrees strong, the number of grains representing in every case an equal number of degrees. This method of testing acids is a modification of that introduced by the French chemists, and though of course only conventional, and principally confined to commercial purposes, is especially adapted to practical men but little conversant with chemistry, yet very ready in retaining or calculating any thing on the centesimal scale, from its similarity to monetary language and reckoning.

All the liquid acids admit of being tested, with more or less accuracy, by ascertaining their sp. gr., and where this plan is applicable, it will be described in its alphabetical order.

In conclusion, it may be remarked, that when the acid is costly or scarce, a small quantity may be examined as easily as a larger one. Thus, instead of 91 grs. mentioned above, (when speaking of acidimetric degrees,) any fractional portion of that weight may be employed instead: 13, 26, 39, or 52 grs. will yield similar results, by merely multiplying the quantity of dried carbonate of soda by 7 .$\frac{7}{2}$.$\frac{7}{3}$ or $\frac{7}{4}$, accordingly as 13 grs. or any of the following numbers have been used; in either case the product will be in acidimetrical degrees. The centesimal method of calculation admits of various useful applications, by means of the Simple Rule of Three.

ACONITE. *Syn.* Wolfsbane, Monkshood, Aconitum napellus. *Caution.* As several articles which follow are made from this plant, it may be necessary to caution parties against the dangerous character of itself and preparations. A fatal case of poisoning by eating the root instead of horseradish is recorded by Dr. Pereira, and more recently twelve persons were poisoned by swallowing ninety grains each of extract of aconite, instead of ext. cochleariæ, three of whom died, and the rest barely escaped losing their lives. (Memoriale della Medicina contemporanea.) *Officinal portions of the plant.* The root and leaves (of the aconitum paniculatum) are the parts ordered to be used by the London college, while the Dublin college orders only the leaves. The aconitum napellus, an equally active species of aconite, is the

one employed for medical purposes in England, the aconitum paniculatum not being procurable in any quantity. (Pereira, Thompson.) *The leaves* should be gathered as soon as the flowers appear. *The root* should be taken up in autumn. When the whole plant is employed, it should be gathered as soon as the flowers begin to open. Herb collectors should be particular as to the period at which they gather the several parts of this plant, as its strength (quantity of aconitina) varies considerably with the time of the year.

ACONITE, EXTRACT OF. *Syn.* Ext. of Wolfsbane, Inspissated Juice of Aconite.

I. (*Extractum Aconiti,* P. L.) *Proc.* Bruise the fresh leaves of aconite, previously sprinkled with water, in a marble mortar, then express the juice, and without depuration, evaporate to the consistence of an extract

II. (*Ed. Ph.*) Beat the fresh leaves of aconite to a pulp, and express the juice; then subject the residuum to percolation with rectified spirit, until the latter passes through without being materially colored; unite the expressed juice and the percolated tincture, filter, distil off the spirit, and evaporate in a vapor or water bath.

Remarks. A variable and uncertain preparation. Numbness and tingling should follow its application to the lips or tongue, if it be of good quality. The extract of the Ed. Ph. is stronger than that of either the London or Dublin. The two latter are prepared in the same manner. *Prod.* 1 cwt. of fresh leaves yield 5 lb. or 6 lb. of extract. *Prop.* Anodyne, sudorific, and narcotic; *very poisonous. Dose.* ½ gr. to 4 grs. once or twice a day, in neuralgic pains, &c.

ACONITE, EXTRACT OF, (Alcoholic.) Make a tincture by macerating the fresh leaves of aconite in twice their weight of rectified spirit, for 14 days; express, filter, and evaporate in a water bath.

Prop. Similar to the last, but much more powerful. It has been exhibited internally in the form of pills, and used externally combined with ointment or plaster. *Dose.* One-twelfth to one-sixth of a grain every three hours.

ACONITE, PILLS OF EXTRACT OF, (Alcoholic.) *Prep.* Alcoholic extract of aconite, 1 gr.; liquorice powder, 12 gr.; simple sirup or mucilage, q. s. *Proc.* Mix the first two articles with enough sirup to form a mass, then divide into six pills. *Dose.* One pill every three or four hours.

Remarks. The utmost care must be taken in weighing and mixing the *ingredients accurately.*

ACONITE, PLASTER OF, (Spread.) Curtis. *Prep.* Gently evaporate the tincture of aconite to the consistence of a soft extract, then spread a very small portion over the surface of a common adhesive plaster. *Use.* Mr. Curtis of Camden-town has strongly recommended this plaster in neuralgia. *Remarks.* A little of the alcoholic extract may be employed with equal success to that obtained fresh from the tincture.

ACONITE, OINTMENT OF. (Dr. Turnbull.) Mix one part of the alcoholic extract with two parts of lard. Employed in neuralgia, &c.

ACONITE, POWDER OF. *Prep.* Dry the leaves cautiously by means of a current of warm dry air, and at once reduce them to powder; place the product in dry vials, which must be well corked, and kept in an obscure place.

Use, Dose, &c. It has been given in doses of 1 to 2 grs. in neuralgia, rheumatism, gout, scrofula, syphilis, &c., but its employment requires great caution.

Remarks. This powder is very liable to spoil by keeping, and unless recently and carefully prepared, can hardly be depended upon If the quality be good, a numbness and tingling of the tongue and lips will follow soon after tasting it.

ACONITE, SOLUTION OF. *Prep.* Dissolve 4 scr. of extract of aconite in 30 scr. of antimonial wine.

Remarks. This preparation is highly extolled by Drs. Richter and Busse in rheumatic affections, especially of a chronic kind, as well as dental pains of a similar nature. *Dose.* 15 to 25 drops every two hours, gradually raised to 40 or 60 drops, in chronic rheumatic pains, toothache, cramp of the stomach, &c. (Hufeland's Journal.) 1 dr. of the extract to ℥j of the wine would be more convenient proportions, and but very slightly vary from the above.

ACONITE, TINCTURE OF. I. (Pereira.) *Prep.* Reduce lb. i of newly dried root of aconite to a coarse powder, and digest it in 1½ pint of rectified spirit of wine for 14 days; then express the tincture and filter. *Dose.* 2 to 5 drops three times daily (carefully watching its effects) in rheumatism, gout, syphilis, &c., where a narcotic sedative is indicated. *Remarks.* Diluted with water it forms an excellent embrocation in rheumatism, neuralgia, &c. Applied by means of a small sponge, tied to the end of a stick or glass rod. This formula is nearly the same as Dr. Turnbull's.

II. (A. T. Thompson.) *Prep.* ℥ij of the leaves or root to 1 pint of rectified spirits of wine. As above. *Dose.* 5 drops, gradually increased to 10 and upwards to 30 or 40.

III. (Kempf. & Pol. Ph.) *Prep.* Dried leaves of aconite ℥j, proof spirit ℥viij. As above. *Dose.* 5 to 10 drops and upwards.

IV. (P. Codex.) *Prep.* Dried leaves of aconite ℥j, proof spirit ℥iv. As before.

ACONITIC ACID. An acid, discovered by Peschier in the aconitum napellus, and by Braconnot in the equisetum fluviatile. It exists in the juice of the aconite combined with lime.

Prep. Express the juice from the aconitum napellus, previously bruised and sprinkled with water, filter, and add a solution of acetate of lead; collect the precipitate on a filter, wash it well with *cold* distilled water, then place it in a glass vessel with pure water, and pass sulphureted hydrogen gas through the vessel until the whole of the lead is thrown down; lastly, filter and evaporate. It may be purified by resolution in ether.

Prop. A white, odorless, semi-crystalline mass; it tastes sour, dissolves in alcohol, ether, and water, and unites with the alkalis to form soluble aconitates, and with the metallic oxides, salts that are wholly or nearly insoluble in water.

Remarks. It appears to be identical with the true pyrocitric acid obtained by Berzelius and Dahlstroom from citric acid.

ACONITINA. *Syn.* Aconitia. Aconita. Aconitin Aconitine. One of the new vegeto-alkaline bodies to which chemists have given the

generic name of alkaloid, discovered by Gieger and Hesse in 1833. It exists in a greater or less quantity in every species of the genus aconitum, but the aconitum napellus is that usually employed in England. The alkali is found in every part of the plant, but more especially in the roots, where it is combined with a peculiar acid, (aconitic.)

Prep. (*Process of the London Ph.*) *Ing.* Root of aconite, dried and pounded, lbs. ij; rectified spirit 3 gals.; dilute sulphuric acid, solution of ammonia, purified animal charcoal, of each a sufficient quantity. *Proc.* Boil the aconite with a gallon of the spirit for an hour in a retort to which a receiver is annexed; pour off the liquor, and what remains again boil with another gallon of the spirit and the recently distilled spirit, and pour off this liquor. Let the same thing be done a third time. Then express the aconite; and all the liquors being mixed and strained, let the spirit distil: evaporate what remains to the consistence of an extract. Dissolve this in water, and filter. Evaporate the liquor by a gentle heat, so that it may acquire the consistence of a sirup. To this add of dilute sulphuric acid mixed with distilled water, a sufficient quantity to dissolve the aconitine. Next drop into it the solution of ammonia, and dissolve the precipitated aconitine in dilute sulphuric acid, mixed with water as before. Then add the animal charcoal, thoroughly shaking the vessel every quarter of an hour; lastly, strain and again drop in the solution of ammonia, in order to throw down the aconitine; wash and dry.

II. M. Hesse has obtained this alkaloid by adding hydrate of magnesia to the decoction of the dried leaves of the aconitum napellus, washing the precipitate thus formed with water, drying, and then treating it with boiling alcohol, which dissolves out the aconitina, and deposites greater part of it again on cooling, and the remainder by gentle evaporation.

Prop. Pure aconitina is generally in the form of a white odorless powder, soluble in 150 times its weight of water at 60°, and in 50 parts at 212°. It dissolves freely in hot alcohol and ether, and in the dilute acids forming salts. By the formation and decomposition of the latter, it may be obtained very pure, when it will crystallize from its alcoholic solution submitted to spontaneous evaporation. In this process much, however, is left behind in the mother liquor, and suffers decomposition.

Uses. Dr. Turnbull is the only practitioner who has employed this substance as a medicine in England. He recommended it in very minute doses, in the form of pills, for neuralgic affections, and externally made into an embrocation and an ointment. The danger attending its internal exhibition, from the slightest error or want of skill in dispensing it, has lately induced even Dr. Turnbull to cease to employ it in that way.

Pur. There is a spurious article imported under the name of aconitina, which sells for about 3d. a grain, but possesses none of the properties of that prepared by Mr. Morson. It has a yellowish gray color, is only partially soluble in alcohol and ether, and leaves a white calcareous ash, when burnt in a capsule of glass or platina. The London College say that it should be "largely soluble in sulphuric ether, less so in alcohol, and nearly insoluble in water." "It is totally destroyed by heat, leaving *no salt of lime.*"

Remarks. This is one of the most poisonous substances with which we are acquainted. Too much caution cannot, therefore, be taken in every thing that concerns it. It is stated that so small a portion as the one-fiftieth of a grain of Mr. Morson's aconitina has endangered the life of an individual. (Pereira, Thompson.) The young dispenser should be very careful to satisfy himself as to the nature of the termination of the Latin word, when dispensing this subtile article. The word *aconiti*, in loose writing, may greatly resemble the name of the alkaloid, to the unaccustomed eye; but the adoption of the latter article for the former would certainly doom the patient to an untimely grave, and subject the dispenser to all the inconvenience of legal proceedings. It is scarcely necessary to caution the inexpert and careless to avoid this article altogether. There is but one maker in England, and that is Mr. Morson; and the price at which he sells his preparation (3s. 6d. a grain) will give some idea of the danger and difficulties attending its manufacture. This alkaloid is said to possess "extraordinary power in some affections, and would doubtless be very extensively employed, were it not for its extreme costliness." The reason for introducing this article into the L. P. when *so many others, in general use among practitioners, are omitted*, remains a problem which it has been attempted in vain to solve.

ACONITINA OINTMENT. (Turnbull.) *Prep.* Aconitina, 16 grs.; alcohol, 12 drops; olive oil, ʒss; lard, ℥j. *Proc.* Rub the alkaloid with the spirit, then add the oil by drops, and after it is thoroughly mixed, pour in the lard rendered *nearly liquid* by heat; stir well until cold. *Use.* A *small* portion is applied by the tips of the fingers and gentle friction, in neuralgic and rheumatic affections, &c.

ACONITINA, SOLUTION OF. *Syn.* Embrocation of Aconitina. (*Turnbull.*) *Prep.* Dissolve 8 grs. of aconitina in f℥ij of spirit of wine. *Use.* As an embrocation in the above cases. It should be applied by means of a sponge fastened to the end of a stick or glass rod.

Caution. Neither this nor the preceding article, nor any similar preparation of the alcoholic extract, should be used if the skin be abraded.

ACORUS. *Syn.* Sweet Flag. Calamus aromaticus. Ac. verus. Ac. Asiaticus. Ac. calamus. The root of this plant has been employed in medicine ever since the days of Hippocrates. It has been recommended in ague, and combined with bitters in dyspepsia, &c. It is generally taken in the form of *infusion or powder.* The former is made by digesting 1 oz. of the bruised root in 1 pint of boiling water for an hour in a covered vessel. The dose is a teacupful. *The powder* is given in doses of ℈j to ʒj once or twice a day.

Remarks. By distillation with water, the fresh root yields a fragrant *essential oil*, used in perfumery and for flavoring spirit. It is sometimes given in stomach complaints: 1 drop on a piece of sugar. *A fragrant water*, also used for similar purposes to the infusion and oil, is made by distilling 1 lb. of the root along with 2 gallons of water, drawing over only 1 gallon.

ACROLEINE. When fixed oils are exposed to a heat sufficient to produce ebullition, acroleine, mixed with carbureted hydrogen, is given off. By passing the vapor through a series of well-cooled bottles, partly filled with water; and by redistilling the contents of the second and third bottles, this substance will be obtained in the form of an oily liquid, possessing a very disagreeable odor. It has never been obtained in an isolated state, and little is known concerning its precise composition.

ADIPIC ACID. One of a series of new acids discovered by Laurent, among the products of the oxidation of oleic acid, by means of pure colorless nitric acid.

Prep. Gently evaporate the mother liquor, left from the process of preparing pimelic acid, set it aside for some days, and then collect the crystals deposited; repeat this operation until the liquor ceases to yield crystals. Then dissolve them in hot water, skim off the oil, filter, evaporate, and crystallize. Dissolve in ether, and evaporate to one half; collect the crystals and repeat the process a second time; next dissolve the two crops of crystals separately in alcohol, when adipic acid, in roundish crystalline grains, and dipic acid, in plates, will be obtained.

Prop. Color brown, soluble in hot water, volatile above 266°. It unites with the bases, forming salts called adipates, which are mostly soluble.

ADIPOCERE. *Syn.* Adipocera. (Adeps *Fat*, and Cera *Wax*.) Grave Wax. *Hist.* On the removal of the bodies from the Cimetière des Innocens in Paris, in 1786, it was found that they were for the most part converted into a substance resembling spermaceti, to which the name of adipocere was given. Fourcroy was the first who submitted this substance to a scientific examination, though it is said to have been previously known to grave-diggers, and that it is even mentioned by Lord Bacon.

App. It was proposed by Lavoisier to produce this substance artificially, for the purposes of the arts. Dr. Gibbs of Oxford found that lean beef, suspended in running water, was converted into fat (adipocere) at the end of a month. Three pieces of lean mutton were immersed in each of the three mineral acids, in separate vessels. At the end of three days, that in the nitric acid had changed into a soft fatty matter; that in the muriatic was less altered; while that immersed in the sulphuric had become black and carbonized. Attempts have been made to convert the dead bodies of cattle (carrion) into adipocere, for the purposes of the candlemaker and the soap-boiler, but without success. From the experiments of Von Harkhol, extending over a period of 25 years, it appears that the carcasses of mammalia, immersed in running water, are after a lapse of three years converted into a pure, hard, scentless fat, resembling white wax, perfectly fit for the manufacture of soap and candles. Exposure to stagnant water gives more fat, but of an impurer kind. For further information on this subject, the reader is referred to 'Ure's Chemical Dictionary,' and to the 'Dictionary of Arts, Manufactures, and Mines,' by the same author.

ADULTERATION. The fraudulent corruption of pure articles, by admixture with others of less value, for the sake of greater gain. The means of detecting the adulterations generally met with in trade, will be found explained, under each article of importance, in its alphabetical order.

ÆGIRINON. A once popular ointment, made by macerating the fruit of the poplar, in six times its weight of melted lard, and straining. It is much employed in some parts of the Continent.

ÆSCULINE. A new alkaline substance, said to have been found in the horse-chestnut. It is probably extractive matter combined with lime.

ÆTHIOPS. *Syn.* Ethiops. A name give by the older chemists to several black powders on account of their color. (See the following articles.)

ÆTHIOPS, ANIMAL. This was a powder obtained by burning various animals, as the hedgehog, mole, sparrow, &c., to a cinder.

ÆTHIOPS, ANTIMONIAL. *Syn.* Ethiops of Antimony. Æthiops antimonialis. *Prep.* Sulphuret of antimony, two parts; quicksilver, one part. *Proc.* Triturate until the globules are extinguished. *Dose.* 3 to 5 grs., gradually raised to a scruple, in some cutaneous diseases.

ÆTHIOPS, GOLDEN. *Syn.* Æthiops auripigmentum. This æthiops is made by triturating together the red sulphuret of arsenic and metallic mercury. It is poisonous, and is never employed in medicine at the present day.

ÆTHIOPS, JOVIALIS. Prepared by rubbing together equal parts of tin, quicksilver, and sulphur. It was once given in skin diseases.

ÆTHOGEN. A compound of nitrogen with boron, named from its combinations with the metals, producing a phosphorescent light, in the oxidating flame of the blow-pipe.

Prep. Mix seven parts of powdered anhydrous boracic acid, with nine parts of melon, place the mixture in a crucible lined with charcoal, and apply heat, then transfer the product into a well-stopped vial. (Balmain.)

Prop. A light powder, resembling magnesia, infusible, and nearly insoluble in water. It forms compounds with the metals, called æthonides. These may be prepared by either exposing a mixture of the metal and æthogen to heat, or a mixture of the cyanide of the metal with boracic acid

AGRICULTURE. (From *ager*, a field, and *colo*, I till.) The art or business of the farmer; the cultivation of the soil in large quantities, for the purpose of raising crops and live stock. In its more extended sense, it includes *road-making*, *embanking*, *draining*, *planting*, *&c.* It is one of the most important of the useful arts, and when combined with chemistry is not unworthy of the name of science. The following short sketch of the history and principles of agriculture is from the pen of J. C. Loudon, F. L. S., H. S., &c.

Hist. "*The origin of agriculture* may be traced to remote antiquity, and was doubtless coeval with that of fixed property. In the primeval state of society, the sole riches of the husbandman consisted of flocks and herds, which were kept in a state of movement from one point to another, in search of pasturage and water; but as population increased, mankind adopted a fixed abode; this could only be done by bestowing on the site a certain degree of labor and care, which became as it were the *price paid* for constituting it *private property*. At this point in the progress of civiliza-

tion, agriculture may be said to have commenced. Previously, the natural products of the soil were merely consumed where they were found, but *now* men sought to increase them by culture.

"*The culture of land* will be found to have depended in every country principally on its climate and civilization; though partly also on its government and population. In the warmer climates, where nature produces fruits in the greatest abundance, for the food of both men and animals, and where very little care is required to procure shelter or clothing, agriculture has made but little progress; because it is comparatively unnecessary for the prosperity of the inhabitants. In climates of a directly opposite character, agriculture has made equally slight progress, from the natural obstacles opposed to it. In such countries, for example, as Greenland and Kamschatka, only one or two kinds of corn crops can be cultivated, and perennial grasses can scarcely exist; because the ground is covered with snow for eight months of the year; and in these countries agriculture is but little practised, as the chief resources of the inhabitants for food are found in the sea and forest. In intermediate climates, such as those of South Britain, the middle of France, and the North of Italy, the soil may be labored by man throughout the whole year, and there is scarcely any limit to the kind of crops which may be raised on it. In such climates, agriculture is calculated to attain the highest degree of perfection; and comparing different parts of the zones of this description of climate in both hemispheres, perhaps it may be asserted, that *the best agriculture in the world is to be found in Britain and the North of Italy;* viz., in *East Lothian* and *Norfolk*, in the *Vale of Arno* and on *the banks of the Po*. The kind of agriculture practised in different countries is also of course adapted to the difference of climate. Thus, towards the North Pole, the great art of the cultivator would be to increase the heat; or, rather, in adopting such measures as would best guard plants and animals against cold, rains, and the vicissitudes of the weather. Towards the south, on the other hand, the art of the cultivator would be chiefly directed to moderating the extreme heat and supplying moisture. It thus appears that the agriculture of any country depends on its latitude; and that in high and low latitudes, where there are greater extremes of climate and temperature to contend with, agriculture must be of a more difficult and hazardous description than in intermediate or more temperate climates, such as that of Syria, where the art is supposed to have originated, or in Europe, where it may be considered as having attained its highest degree of perfection.

"In tracing the progress of this art in civilized countries, we have only to follow the chronology of general history. As the Greeks and Romans appear to have arrived at as great a degree of perfection in legislation as the moderns, so they appear to have attained nearly equal excellence in the practice of agriculture. Till within the present century, very little difference existed between the most approved agriculture of climates analogous to that of Italy, and the agriculture of the Romans as described by Cato, Columella, and other ancient writers. The chief superiority of the moderns consists in their machinery, and in their knowledge of the *science* of the art; the last being of very recent date, and by no means general among practitioners, (farmers.) By science, improved breeds both of plants and animals have been originated, and by modern machinery a more perfect tillage has been produced, and also a more complete separation of the produce from the soil, from the refuse of the plants which bore it, and from all impurities.

"*The history of British agriculture* begins with the Roman Conquest. Julius Cæsar found the inhabitants in a state of semi-barbarism; but Agricola left them in possession of all the arts of civilization then known. Agriculture declined with the invasion of the Saxons; but was preserved through the dark ages after the establishment of Christianity by the intelligence of the religious establishments, who gradually became possessed of the greater portion of the landed property of the country. Agriculture revived in the reign of Henry VIII., and in that of Elizabeth, during the long peace which then prevailed, and the consequent security of property; and it afterwards declined during the civil wars; it again revived during the reigns of William and Mary, Queen Anne, and George I., in consequence of the introduction of the Flemish husbandry, which included the culture of turnips and clover. A still greater stimulus to the art was given during the reign of George III., by the introduction of ploughs drawn by *two* horses, instead of *four* or *six;* of the drill system, and its application to the culture of turnips and potatoes; and by the improvements made in the breeding and rearing live stock, by Bakewell and Culley. Early in the present century, the threshing-machine was an important addition to agricultural machinery; the reaping-machine, the frequent drain system, and the subsoil plough, are improvements just coming into use; and the next grand attempt will probably be the general application of steam, instead of horses and cattle, in tillage and other field operations.

"*The principles of agriculture* are derived from a knowledge of the nature of plants and animals, of soils and manures, and of the climate, the seasons, and the weather. Plants are organized beings, which take up their food by means of roots, from the interior of the soil;* animals are organized beings, which select their food from vegetables growing on the surface of the soil, or from other animals, and this food is prepared before being absorbed into their system, by means of a stomach. The climate of a country determines both the plants and the animals which can be produced in it; and the seasons and the weather, the times when the plants and animals of the given climates are in particular states of vigor or torpidity; and when certain operations of culture can be performed on them or on the soil.

"The nature of these elementary materials being understood, even though imperfectly, certain improvements can be effected in them by art, which are greatly conducive to the increase of agricultural produce. The kinds of plants and animals suitable to any given climate, soil, or season, are determined by the laws of nature; but from among these kinds it is in the power of man to

* And by means of their leaves from the atmosphere.—A. J. C.

make a selection; and with the plants and animals so selected, to originate others, adapted to his purposes in a superior degree. Hence the importance of selecting certain breeds of animals, rather than others, and of making choice not merely of *one* kind of bread corn rather than another, but of *particular varieties of that corn.* Thus, in the case of wheat, there are some kinds, the grains of which, under no circumstances, weigh *more* than from 50 to 55 lbs. per bushel; while there are others which never weigh *less* than 60 lbs. a bushel. The nourishment of plants has been found to depend chiefly on organized matter contained in the soil, and produced chiefly by the decay of other plants. This is a law of nature, which, followed up by man, has led to the use of manures; as the fact everywhere observed, that no plant can live without water, has led to irrigation; and, as the observation that the excess of water is injurious, has led to surface and under-draining. *The influence of temperature and shelter* over the growth of plants, and the thriving of animals, is everywhere observable in wild nature; and though the temperature of a climate cannot be changed, yet that of most localities may be improved by shelter from cold winds, and by diminishing evaporation from the surface, by means of surface and under-draining, to draw off the superfluous water. The most important principles in the theory of agriculture are those which relate to the improvements of plants and animals, and of the soil.

"*The improvement of the soil* may be comprised under two heads,—*the improvement of its earthy part;* and *the increase of the organized matter added to the earth.* The improvement of the soil, considered as a mixture of different earths, consists in rendering it more or less retentive of water, by diminishing or increasing the size of the particles of which it is composed: for example, by the addition of clay in some cases, and of sand in others; and by improving the earthy condition of the soil, by the addition of such earths as may be in too small quantities, or absent altogether. It has been found, from experience, that those soils which are composed of *several* primitive earths are naturally more productive than those that consist of only *one* earth, all other circumstances being the same; and it has also been found that no soil will maintain its fertility, for any length of time, that does not contain a certain portion of calcareous earth in its composition. Hence, one of the most common plans of improving all soils not calcareous, is by the addition of lime; and of all other soils by mixing them with such as are of an opposite description.

"All soils are rendered more productive by the addition of organized matter, or what are called *manures.* Manures may be either composed of animal or vegetable matter; and these may be either applied separately or together, and in a fresh state or in a state of decay. It has been found from experience, and explained from chemical experiments, that every description of manure is rendered more effective by being made to undergo the putrefactive fermentation before it is applied; and this process is carried on with solid manures, in heaps or dunghills, and with liquid manure in tanks or wells. In the application of manure to soils, the great object of the cultivator is to apply *enough for the ensuing crop, and as little more as possible;* because all that is applied and not immediately used, is liable, to a certain extent, to have its particles carried off by evaporation (volatilization) into the atmosphere, or by rain into rivers or the sea. But even if this were not the case, to apply manure to a soil where it would not be immediately turned into a crop, would be an expenditure of capital without interest."

Draining, or "the operation of freeing a soil from superfluous water, is of equal or perhaps more importance than supplying it with manure; because, though without manure, plants will not grow with *great* luxuriance and *vigor*, yet with *too much* water, *they will not grow at all*, or *will become sickly.* The excess of water may proceed from three causes: an extremely moist climate, the only alleviation to which is arranging the surface with frequent furrows, and short slopes between them, so as to carry off the rain as soon as it falls; a soil very retentive of moisture, so as to hold it like a sponge, in which frequent under-drains, as near together as the surface furrows, are required; and, lastly, a soil lying over a subsoil abounding in springs, or, in other words, which has the substrata charged with water, which is continually oozing out through the surface soil. The remedy for this last evil is, by under-drains of considerable depth, so arranged as to collect the water from the substrata, and carry it off before it reaches the surface soil."

Comminution and labor tend considerably to promote the fertility of soils. "After draining, and being rendered of a proper texture and composition, by the admixture of such earthy ingredients as may be wanting, a soil requires, to render it fit to be easily penetrated by the roots of plants, to be frequently stirred and comminuted. This is done by the mechanical operations of ploughing, harrowing, &c., which, aided by the alternate action of droughts and rains, frosts and thaws, and summer and winter, have the effect of pulverizing the soil. To maintain a soil in a fertile state, it is not only necessary to supply it with manure, in proportion to the crops which have been carried from it, but to *vary* the crops which it is made to produce. It has been found, from experience, that crops of plants belonging to the *same natural family do not succeed so well after each other*, as when *crops of a different family* are made to intervene. Thus, the several grasses alternate better with root or herbage crops, than with one another; or, one of those grasses of which the seed is ripened will alternate better with another in which the herbage only constitutes the crop, than with one of the same kind as itself. Something analogous to the succession of crops takes place also with regard to the pasturage of animals, and it is found advantageous to put cattle in a field that has been grazed by horses, rather than to put *horses* after *horses*, or *cattle* after *cattle.*

"Thus, the *principles of agriculture* may be comprised under the *selection of breeds of plants and animals;* the *improvement of the soil and subsoil;* the *culture or movement of the soil;* the *improvement of the local climate by shelter and drying;* and the *succession of crops.* All these principles have been derived from experience; and they are only partly accounted for by chemistry

or natural philosophy. They are not, however, on that account, the less true and useful. It is singular that they should all have been known to the Romans, and, to all appearance, as fully as to modern cultivators.

"*The practice of agriculture*, in Britain, may be included under the heads of the *choice, hiring, and stocking a farm;* and ITS GENERAL CULTURE AND MANAGEMENT. In the *choice of a farm*, in any given county, the soil is of the greatest importance; because, though this may be so improved by art and expense, as almost to render a bad soil equal to a good one, yet in practice this would be so expensive as by no means to answer the purpose of the farmer. It may be thought that the vicinity of good roads, of a canal, a river, or a market town, are objects of more importance than the nature of the soil; but this is not the case, because, supposing the roads to be bad and the markets at a distance, it is only necessary to change the system of cultivation and management, and to turn the produce of the farm into some description of live stock, which may be driven to any distance, even over a country without roads. If it be alleged that the nature of the climate is of paramount importance to the soil, in the choice of a farm, we allow that in an extended sense it is; for example, if a cultivator had the choice of any part of Europe, there are doubtless many districts where the climate is far more favorable for all the operations and products of agriculture than others; and if even he had the choice of every part of Britain, he might find some localities much more favorable than others. In general, however, the actual choice of any cultivator lies within a *given* locality, where the climate, in a practical point of view, is everywhere the same. Next to *soil* and *climate* in the choice of a farm, the *state of the buildings and fences* on it, the *state of the roads*, and the *distance from a market town, a canal, or a seaport*, are of importance. Without buildings of sufficient extent, and properly situated, and of the proper kinds, the business of a farm cannot be carried on; and though some farms and some kinds of farming may be conducted without fences, yet, in general, fences are as necessary as roads. The last circumstance which we shall notice in this cursory glance, is the *nature of* THE TENURE by which the farm is to be held, and on the covenants and conditions of the lease. No cultivator who calculates on the employment of considerable capital, will risk it on lands of another, without some security for having it returned; and this security is a lease for a fixed number of years. On the other hand, no proprietor of lands will delegate the possession of them to another, for a fixed number of years, without a valuable consideration; and this he reserves to himself in the lease, under the denomination of rent. As lands in a state of cultivation, and buildings and fences in a state of repair, are liable to be injured and deteriorated in value by bad management or neglect, the proprietor guards against these accidents by certain conditions in the lease.

"*The culture and management* of a farm depend jointly on the soil and climate, and on the kind of produce most in demand and reckoned most profitable. In the mountainous districts of Great Britain, where the climate is cold, almost the only kind of farming practised is that of breeding and rearing different kinds of live stock, such as sheep or cattle, which are sold for being fattened in more favorable districts; or horses, in order to supply the demand for these animals for the purposes of draught or saddle. The mountainous districts of Scotland and Wales are chiefly devoted to the breeding and rearing of sheep and black cattle, which are sold to the farmers of the low countries, in both kingdoms, in order to be fattened for the shambles. The hilly districts of Yorkshire and Lancashire are chiefly employed in breeding and rearing of horses. In the low country of the *east* coast of Great Britain, the climate being dry, is favorable to the culture of corn; while on the *west* coast, and in *Ireland* generally, the climate being moist, is more favorable to pasture.

"*The farm products* most universally in demand are corn and butchers' meat, and these may be produced on every farm, the soil of which admits of being kept alternately in tillage and in grass. Butchers' meat may be produced in much greater abundance on such soils as admit of the culture of root and herbage crops, such as turnips, potatoes, and clover; while corn may be produced most abundantly in strong, loamy soils, within reach of extensive sources of manure. The most profitable description of crop will frequently be found to be different from that which is in most general demand; for example, in the neighborhood of a large town, the culture of culinary vegetables, on a large scale, in what are called *farm gardens*, is generally far more profitable than the raising of corn or butchers' meat. Even the raising of food for cattle, in such situations, is found to yield more profit than ordinary farming. There are also particular crops which may be occasionally cultivated, which yield *extraordinary profits;* such as drugs used in dyeing, or in some manufacture not common; plants of some new and improved variety of the kinds in general cultivation, for their seed, &c.

"*The agriculture of Britain*, and especially that of the low countries of Scotland, *excels that of most other countries having similar climates*, from the superior skill, intelligence, and capital of the farmer; the considerable length of the lease which is granted by the landlord; the superiority of the implements and machines employed; and the improved breeds of animals and plants which are reared or cultivated. Perhaps the nearest approach to perfection in the culture of arable land, in any part of Britain, is made in some parts of East Lothian; where, in consequence of deep-ploughing, substituting under-drains for furrows, regularly supplying manure, and alternating *cleaning* and *restoring crops* with *exhausting crops*, as great an amount of produce is obtained as can stand on the surface at *one* time. The agriculture of Britain is most defective in the southern districts of the island, in consequence of the farmers being the very opposite of those in the northern districts, the want or the shortness of the leases, and the restrictive clauses of those leases, by which the tenant is prevented exercising his own judgment, and is obliged to follow the routine prescribed in the leases of a former age."

For further information on this important subject the reader is referred to the 'Cyclopædia of Agriculture,' which contains the best system of

practical agriculture extant. The scientific agriculturist is also especially advised to peruse the 'Agricultural Chemistry' of Liebig, which explains the application of chemical science to the purposes of the farmer, and the improvement of the soil, and contains much that is valuable of a scientific description connected with agriculture. The principles and practice laid down in these important works, if applied with only moderate skill and industry, cannot fail to produce a degree of success, unattainable by mere unassisted experience. Several articles will also be found in this Cyclopædia, containing information respecting farming. (See the heads FARMING, MANURES.)

AGRIMONY. *Syn.* AGRIMONIA. AGRIMONIA EUPATORIA. A common field plant flowering in June and July. It is frequently given in the form of infusion or powder, in certain skin diseases, especially the itch. It is tonic and stomachic.

AGRIMONY TEA. *Syn.* INFUSION OF AGRIMONY. *Prep.* Pour 1 pint of boiling water on 1 oz. of the fresh tops of agrimony (gathered before the flowers are formed) and 1 oz. of liquorice root, (sliced,) macerate for one hour in a close vessel and a warm situation, then strain for use. *Dose.* A teacupful or more two or three times a day.

AGUE. *Syn.* INTERMITTENT FEVER. A species of fever which comes on only at stated intervals, (hence called intermittent,) leaving the patient between the periods of attack, in apparently good health. The attacks of this disease usually return with great regularity, and have in consequence been distinguished by names having reference to the periods of their visits. From this characteristic nosologists have divided them into the

Quotidian, returning after a lapse of	24	hours.
Tertian	48	do.
Quartan	72	do.

and so on until the interval extends to nine or ten days, as in the nonanus and decimanus.

Symp. I. The *cold stage*, marked by debility, paleness, coldness, drowsiness, and general rigors throughout the body, impaired respiration, nausea, vomiting, &c. These symptoms gradually abate, and are followed by—II. The *hot stage*, distinguished by the usual marks of fever, and, in some cases, violent delirium, &c. After a certain time the disease passes into—III. The *sweating stage*, marked by a copious perspiration breaking out, and a gradual return of most of the functions of the body to their ordinary state. In many cases, however, not only do the symptoms, but the succession of the stages and their duration also vary.

Causes. Exposure to the miasmata of marshes and stagnant water, putrefying animal and vegetable matter, &c., poor diet, exposure to cold and damps, damp bed-chamber or linen; excessive grief, fatigue, &c.

Remedial measures. I. *Palliative.* An emetic or a full dose of opium or laudanum has been recommended at the commencement of the fit, followed by a warm foot, hip, or full bath. Stimulants, as ether, spirits, &c., are also used, but when they fail to *relieve* they tend to aggravate the distemper. When any given method succeeds it should be again had recourse to on the approach of another fit.

II. *Curative.* This consists in the administration of febrifuge medicine during the intermission of the paroxysm. The principal of these are *bark and it* *preparations* and *liquor of arsenic.* The stomac and bowels having been well cleaned out, by th administration of two or three doses of purgativ medicine, 2 to 5 grs. of the disulphate of quinin may be given three or four times daily; or whe this cannot be obtained, 1 to 2 dr. of powdere cinchona bark may be used instead. When th stomach cannot bear the powder, the infusio decoction, or extract may be employed. Quinine properly administered, generally cures ague. Th solution of arsenite of potassa (liquor arsenicali P. L.) is also a valuable medicine in ague, but it use requires great care and attention. Under th name of "tasteless ague drop," it has cured thou sands. The dose should be at first five drops twic a day, gradually raised to 20 drops. This is th common ague medicine of the fen counties of England. In a certain book of travels through England it is said to be "a common practice for th farmers in the marshy parts of Essex to fetc their wives from the uplands, who seldom live lon in the low countries; so that most of the farmer there have had several wives, and many mak much money by this system of wifeing." Doe this mortality arise from the ague or the agu remedy? It may be further remarked, that warn clothing, and a light nutritious diet should be adopted during the curative course, and if the patien reside in a swampy or marshy district, he shoul remove as quickly as possible to one of a drier an opposite description.

AUGUSTINE. *Syn.* AUGUSTINA. Tromsdor gave this name to a substance found by him in th Saxon beryl, which he conceived to be a base capable of neutralizing the acids. Vauquelin ha since shown it to be a phosphate of lime, (whicl see.)

ALABASTER. A white calcareous or gypseous kind of soft stone, used by sculptors, and fo casting. The variety employed for the latter purpose is that most generally known, and when burnt forms the substance called *plaster of Paris.*

ALABASTER, OR PLASTER, TO BRONZE. I. Prepare the surface by sizing i over once or twice, and when dry touch the prominent parts of the figure with the bronze No. 1, an the remainder with No. 2. Then soften down th lines of mixture of the two paints with a badger' hair tool.

Bronze 1. Grind equal parts of Dutch meta and the following paint together, and thin the mixture with a little oil or turpentine.

Bronze 2. Grind Prussian blue, verdigris, an ochre separately with oil, then mix them togethe in such proportions as will produce a bronze gree color.

II. Touch over the prominent parts of the figure with Bessimer's gold paint, or instead thereof use gold or Dutch leaf, then cover the remainde of the figure as before, with the paint No. 2.

Remarks. When the lights are managed wit taste, especially on the prominent parts of the features in a statue, it produces a grand effect. (See BRONZING.)

ALABASTER, TO CLEAN. *Proc.* Wash the article with warm soap and water, then rinse in clean water. If the surface is polished it must be finished by touching it over with shave-grass,

and afterwards with French chalk, or talc, as directed under the article on Polishing Alabaster. Grease spots may be removed with a little *clean* oil of turpentine.

ALABASTER, TO ETCH. *Proc.* Cover every part of the surface of the model or cast, except the portion to be etched, with a mixture of one part of white wax, dissolved in four parts of oil of turpentine, thickened with finely powdered white-lead. When this coating has set, immerse the article in pure water, and allow it to remain for from 20 to 50 hours, according to the effect intended to be produced. Then take it out, remove the superfluous water, wash off the varnish with oil of turpentine, and carefully brush the etched parts over with powdered gypsum.

ALABASTER, TO HARDEN. *Proc.* I. Mix up the plaster of Paris with a weak solution of gum Arabic, (1 oz. to 1 pint of water,) or, for common purposes, a weak solution of size. *Remarks.* This not only renders the plaster harder, but gives the surface a pleasing smoothness. (See also KEENE'S MARBLE CEMENT.)

II. Expose the pieces in a baker's oven for 24 hours or longer, according to their thickness, then withdraw them, and when cool, dip them twice into pure river water, letting them remain immersed each time from 2 to 5 minutes; lastly, expose them to the air for 3 or 4 days before polishing. (M. Tissot.) *Remarks.* This plan is followed for pieces of statuary, &c. worked out of the solid gypsum. It is not adapted *so well* to plaster casts.

ALABASTER, TO JOIN. Ornaments of alabaster or plaster may be joined together by means of a little white of egg, thickened with finely-powdered quicklime, or by a mixture of newly-baked and finely-powdered plaster of Paris, mixed up with the least possible quantity of water.

ALABASTER, TO POLISH. *Proc.* I. The object, received in the rough state from the hands of the sculptor or turner, is rubbed with finely-powdered pumice-stone, or dried shave-grass (equisetum) and water, and afterwards with a paste formed of finely-powdered and sifted slaked lime and water. The rough polish thus produced is then brought up and finished off by friction with finely-powdered talc, or French chalk, until a satiny lustre is produced.

II. Dip the cast or model, previously warmed, and suspended by a fine silken cord or wire, into the purest white wax, melted in any suitable vessel. The operation should be repeated until the liquid wax begins to rest unabsorbed on the surface of the plaster, when the article must be placed aside (suspended) until the next day, when it may be polished with a *clean* brush. *Remarks.* None but the hardest, purest, and whitest wax will do for the above purpose. That commonly sold is mixed with spermaceti, stearine, or tallow, and not unfrequently with potato starch.

III. Suspend the article, well cleaned from dust, by means of a silk cord or wire, in a wooden trough or other suitably-shaped vessel, of glass or earthenware; then cover it with a strong and perfectly clear solution of alum. Let it remain until a sufficient quantity of the salt has crystallized on the surface, when it should be withdrawn and polished with a wet cloth. *Remarks.* I have seen beautiful imitations of marble produced in this manner, but the process requires great care and address.

ALABASTER, TO STAIN OR COLOR. *Proc.* I. Mix various colored powders or solutions with the plaster, at the time of mixing it up with water. *Remarks.* A little terra de Sienna, in very fine powder, or ground with water, added to the water employed to mix up the plaster, imparts a pleasing color to busts, statues, medallions, &c.

II. Objects formed from the solid alabaster may be stained in the same way, and with the same materials as marble. (See MARBLE.)

ALAQUECA STYPTIC. A stone used by the Indians to stop local bleeding. It is iron pyrites.

ALBUM RHASIS. An ointment composed of white-lead and lard, invented by and named after the Arabian physician Rhazes.

ALBUMEN. *Syn.* ALBUMEN (*Lat.*) The white of egg and the serum of the blood contain this substance in a sufficiently pure state for all the purposes of the arts. *Prop.* The acids, metallic salts, alcohol, and heat, coagulate albumen; hence it is incompatible with solutions containing them. Strong oil of vitriol turns it black in the cold, but on applying a gentle heat, a gorgeous red-colored solution is produced. (Dr. Hope.) Strong muriatic acid gives it a violet tinge. *Uses.* As a glaze, or species of varnish, and as a clarifier for wines, sirups, &c.

ALBUMEN, PURE OR SOLID. *Prep.* Agitate the white of egg with 10 or 12 times its weight of alcohol, and collect the precipitated flocculi on a muslin filter. *Prop.* Insoluble in pure water, unless it be heated to 150° C. or 302° F. (Wohler and Vogel.)

ALBUMEN POWDER. *Syn.* FLAKE ALBUMEN. SOLUBLE SOLID ALBUMEN. *Prep.* Expose the strained white of egg, in a thin stratum, to a current of dry air, until it concretes into a solid transparent substance, resembling horn. In this state it may be kept any length of time, or it may be further dried until brittle, and then powdered.

II. Substitute the serum of bullock's blood for the white of egg in the last formula.

Prop., &c. Soluble in cold water, forming a solution possessing all the properties of fresh albumen. *Use.* As a clarifier; exported in quantity to the sugar plantations of the West Indies. It is prepared for use by stirring it with cold water until it is dissolved, when it is whisked to a froth in the usual way, before adding it to the liquid to be clarified.

ALBUMEN, TESTS FOR. I. A solution of bichloride of mercury dropped into a fluid containing albumen, occasions a white precipitate. *Sensibility.* $\frac{1}{2000}$. (Bostock.)

II. Tannin or tincture of galls gives a yellow, pitchy precipitate.

ALCAHEST. *Syn.* ALKAHEST. A word of uncertain meaning, frequently applied by the alchemists to liquids which they thought to possess great solvent powers.

ALCAHEST OF GLAUBER. *Syn.* ALCAHEST GLAUBERI. Obtained by detonating nitre on hot coals, and then exposing it in a damp place until it runs into an oily-looking fluid. It thus becomes oil of tartar.

ALCAHEST RESPURII. Obtained by de-

tonating a mixture of nitre and zinc filings, powdering the resulting scoriæ, agitating it with water, and filtering. The filtered liquor contains the alcahest.

ALCAHEST ZWELFERI. Acetic acid obtained by the dry distillation of verdigris.

ALCARRAZAS. A species of porous pottery, made in Spain, for the purpose of cooling water, by its transudation and copious evaporation from the sides of the vessel. Vessels made in either of the following ways possess similar properties.

Prep. I. Well mix, in the dry state, equal parts of silicious sand and good clay, then bring it to a proper consistence with brine, adding afterwards a considerable quantity of common salt, which must be well incorporated with the clay by beating. The vessels formed of this mixture must be only half baked.

II. Mix up your clay with twice its weight of charcoal, in powder, and bake it until the latter substance is perfectly burnt out.

ALCOHOL. *Syn.* Alkohol. Alkahol. Alcahol. Höchst Rectifizirter Weingeist (*Ger.*) Alcohol (*Fr.*) Alcoole (*Ital.*) Alchool. Alcool. Alcol. Alkol (*obs.*) From the Arabic *al* the, and *kohol* antimony. A term originally applied to several chemical preparations, presumed to be very subtile, or brought to the highest state of tenuity, but at the present day restricted to pure spirit of wine, of the strongest class.

Hist. Fermented liquors were known to antiquity. "Noah planted a vineyard; and he drank of the wine, and was drunken;" an event supposed to have happened 2348 years before the birth of Christ. Wine and fermented liquors are also mentioned by the earlier profane historians; but the period at which they were first submitted to distillation is undecided. By some, the Chinese are thought to have possessed the earliest knowledge of this process; others think that the northern nations of Europe were the first who were acquainted with the art of distillation. Herodotus, however, mentions date spirit as an article of commerce in Babylonia (B. C. 445.) Albucacis, in the 12th century, taught the method of procuring spirit from wine; but the process was doubtless known long before that time. Raymond Lully, in the 13th century, showed the way to concentrate it, by means of carbonate of potassa; after which time it gradually rose into note as an article of trade and commerce. At the present day, more capital is, perhaps, embarked in the various processes of distillation than in any similar branch of business.

Sources. Alcohol is a product of the fermentation of vegetable juices or solutions containing saccharine matter, or some substance (as starch) capable of conversion into sugar. In this state, it forms but a small portion of the fermented liquor, (as in wine, beer, brewer's wash, &c.,) and is obtained in an isolated form by the process of distillation. It is a component part of nearly all intoxicating beverages, and gives them their peculiar properties. Brandy, gin, and rum contain about half their bulk of alcohol. Dilute alcohol may be procured, by the ordinary process of distillation, from *all* fermented liquors; when drawn from wine, (as in France,) it constitutes *brandy*; when from the juice of the sugar-cane, it is called *rum*; and when from malt, grain, or molasses, (as in England,) it is called *malt*, *grain*, or *molasses spirit*. The following table of the sources of spirit will no doubt prove interesting to the reader:

Table of the Sources of the various Spirits of Commerce, by Dr. A. T. Thompson.

Names.	Materials from which they are distilled.	Countries producing them.
Agua ardiente	Pulque, the fermented juice of the agave	Mexico.
Arrack	Coarse palm sugar, named jaggery, fermented with the bark of the mimosa *leucophlea*; also from rice and the fermented juice of the palm	India
Var. Mahwah Arrack	Flowers of the Madhuca tree, bassia *butyracea*	India.
Tuba	Palm wine	Philippine Islands.
Araka	Koumis, fermented mare's milk	Tartary.
Araki	Dates	Egypt.
Arika	Fermented cow's milk, a variety of koumis	Tartary, Iceland.
Brandy	Wine, figs, peaches, Persimmon apple, mulberries, and sometimes other fruits	Europe, Asia, N. and S. America; wherever wine is made.
Var. Lau	Rice	Siam.
Rakia	Husks of grapes, mixed with aromatics	Dalmatia.
Rossolio	A compound of brandy, ros-solis, and other plants	Dantzic.
Troster	Husks of grapes, fermented with barley and rye	On the Rhine.
Sekis-kayavodka	Lees of wine and fruit	Scio.
Geneva. Hollands	Malted barley and rye, rectified on juniper berries	Holland.
Var. Gin	Malted barley, rye, potatoes, rectified with turpentine	England.
Goldwasser	Wheat, barley, and rye, rectified with aniseeds, cinnamon, and other spices	Dantzic.
Kirchwasser	Machaleb cherry	Switzerland.
Maraschino	Macarska cherry	Zara, capital of Dalmatia.
Rum	Cane sugar and molasses	West Indies and South America.
Ditto	Maple sugar	North America.
Var. Slatkaia trava	A sweet grass	Kamschatka.
Show-choo	The lees of mandarin, a wine made from boiled rice	China.
Whiskey	Malted and raw barley, rye, oats, and potatoes	Scotland and Ireland.
Ditto	Sloes	South of France.
Y-wer a	The root of the tee-root, baked, pounded, and fermented	Sandwich Islands.
Vino meresel	Distilled from pulque, the fermented juice of the agave *americana*	Mexico.

Remarks. All the different varieties of spirit mentioned in the preceding table, consist of dilute alcohol, holding in solution various quantities of essential oils and coloring matter, and frequently a little ether and extractive. It is the presence and different proportions of these ingredients which give them their distinguishing characters. By subsequent rectification, alcohol of equal purity and strength may be procured from all of them. In the present article, I shall confine myself to a notice of the preparation of pure spirit, or alcohol of the chemist, referring the reader to the heads DISTILLATION, SPIRIT, STILL, RUM, BRANDY, GIN, WHISKEY, &c. for further information.

Prep. I. (*Alcohol of the L. Ph.*) Rectified spirit (sp. gr. 0·838) 1 gallon; chloride of calcium (dried) lb. j. *Proc.* Dissolve the chloride in the spirit, and let 7 pints and 5 fluid ounces distil over. *Remarks.* The sp. gr. of this spirit is 0·815, and as it contains about 7% of water, it would be more appropriately called highly rectified spirit. The process of the Dublin College is of a similar description, except that in addition to the chloride of calcium, 3½ lbs. of dried pearl-ashes (still hot) are used, and the distillation continued until the residuum begins to thicken. Alcohol of the D. P. has the sp. gr. 0·810.

II. (*Alcohol of the E. Ph.*) Rectified spirit, 1 pint; lime, 18 oz. *Proc.* Break the lime into small fragments, pour on the spirit, and heat the mixture gently in a glass matrass (closed) until the lime begins to slake, then withdraw the heat, and preserve the upper part of the vessel cool with damp cloths, until the slaking has finished; next attach a proper refrigeratory, and carefully distil off 17 fluid ounces. *Remarks.* The sp. gr. of the product should be 0·796, in which case it would be very nearly free from water. Should the density exceed ·796, the College states that the distillation must have been begun before the slaking of the lime was finished.

III. (*Absolute Alcohol.*) *a.* Saturate alcohol of 90%, or sp. gr. 0·835 to 0·840, with dried chloride of calcium in powder, and then draw it over in a water bath, with a gentle heat. (Liebig.)

b. Place alcohol of 90% under the exhausted receiver of an air-pump, near a vessel containing quicklime. After the lapse of 3 or 4 days, if the vacuum be well kept up, the spirit will have entirely lost its water. (Graham.) *Remarks.* The best means of operating is to use two shallow circular vessels, of different sizes, and to place the one containing the spirit in the other holding the lime, care being taken to prevent the latter falling over the side of the small vessel into the spirit, as it swells.

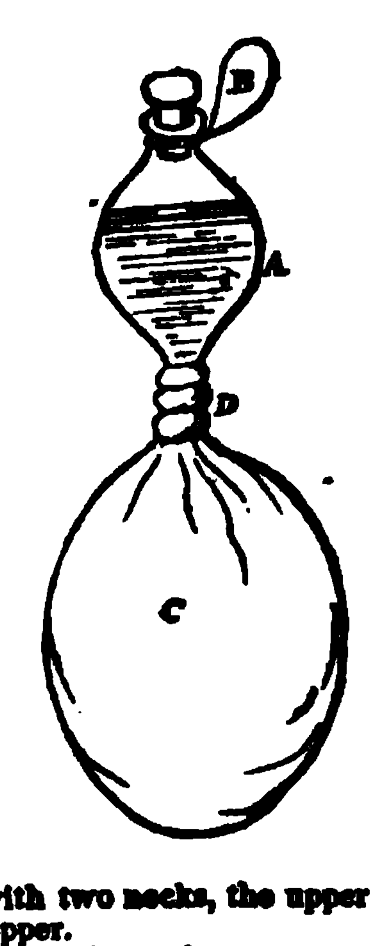
IV. (*Varnish-maker's Alcohol.*) Take the bladder of an ox or calf, soak it for some time in water, then inflate it and carefully free it from the attached fat and vessels; this must be done on both sides. After it is again inflated and dried, smear over the outer surface *twice*, and the inner surface *four* times, with a solution of isinglass. Then nearly fill it with the spirit to be concentrated, leaving only a small space vacant; it is then to be securely fastened, and suspended in a warm situation, at a temperature of about 122° Fahr., over a sand bath, or in the neighborhood of an oven or fire. In six to twelve hours, if the heat be properly conducted, the spirit will be concentrated, and in a little time longer may be rendered nearly free from water (anhydrous) or of the strength of 97 or 98 per cent. (Soëmmering.)

Remarks. This alcohol will be sufficiently pure for all the common purposes of the manufactures, and is an excellent spirit for making varnishes, &c.

The same bladder will serve more than one hundred times; and in fact a *common* bladder, thoroughly cleansed from fat, and washed and dried, may be used without any further preparation. The bladder should be kept full, or else a portion of the spirit will escape through the empty part. To prevent this accident, I have adopted a bottle with a double neck, of the shape of *A*, (see engraving,) by which means I am always able, not only to keep the bladder full, but to empty it and to refill it without any trouble. After the first or second time of using the bladder, I find it gives alcohol sufficiently pure for most experimental purposes. Before hanging the apparatus up, it is better to enclose it in a coarse potato netting, and to suspend it by means of the latter, which will prevent any accident arising from the strain on the neck of the bladder. Should weaker spirit than that directed in the preceding formula be used, to procure alcohol by either method, it must be previously concentrated, or the operation repeated a second time.

Prop. Light, transparent, colorless, volatile, inflammable; mixes in all proportions with water; dissolves resins, essential oils, camphor, bitumen, soaps, sugar, the alkaloids, wax, spermaceti, and various other substances. Boils at 172°; curdles milk; coagulates albumen, and separates both starch and gum from their mucilages; uncongealable by cold; powerfully antiseptic to animal or vegetable substances immersed in it; with acids it forms ethers.

Use. It is used to dissolve resins by the varnish maker; essential oils, by the perfumer; and by the pharmaceutist, to prepare tinctures and many



A, A bottle with two necks, the upper furnished with a ground-glass stopper.
B, Loop of cord to hang the apparatus up by.
C, Bladder containing spirit, filled by means of the bottle *A*.
D, Neck of bladder accurately secured to the under neck of the bottle *A*.

other valuable medicines. It is used to fill the tubes of thermometers required to register extreme degrees of cold; it is frequently burnt in lamps; and, where it is inexpensive, it is used for the manufacture of vinegar. It is employed in medicine, and as a beverage, in a diluted state, (brandy, gin, &c.;) but it is powerfully poisonous when undiluted with water. *Largely diluted* with water, it has been given as a tonic and stimulant, in some cases of colic, &c.; but for this purpose, it is not equal to good brandy or malt spirit, while it is far less agreeable. The properties and uses of the various articles into the composition of which alcohol enters, will be described under their respective heads.

Pur. The presence of water is best known by its specific gravity, (see ALCOHOLOMETRY,) and the absence of other foreign matter, by the following tests:—The London College states, in the notes to the Pharmacopœia, that it should be "colorless; evaporate entirely by heat; combine with water and with ether, retaining its transparency; taste and smell vinous." It should be neutral to test paper. Absolute alcohol has a sp. gr. of 0·792-0·791 at 68° Fahr., and 0·7947 at 60° Fahr.

Tests. I. Add colorless oil of vitriol to the spirit; a red tinge will be produced if essential oil be present. (Liebig.) II. A solution of nitrate of silver added to pure alcohol, does not alter its color or transparency. If it turns *red*, it contains oil or other organic matter. (Vogel.) *Remarks.* This test is very delicate, and is equally applicable to dilute as strong alcohol.

ALCOHOL DE BRUCINE. *Syn.* TINCTURE OF BRUCIA (*Majendie.*) *Prep.* Brucine, 15 grs.; rectified spirit of wine, f ℥j; dissolve. *Remarks.* The action of brucine is similar to strychnine, but in a milder degree. This tincture is given in doses of 5 to 25 drops in paralysis, (without fever,) in dyspepsia, pyrosis, impotence, and various other cases, where strychnine has been prescribed. It is an *active poison.*

ALCOHOL DE CINCHONINE. *Syn.* TINCTURE OF CINCHONINE. ALCOOL DE CINCHONINE. (*Majendie.*) *Prep.* Sulphate of cinchonine, 8 grs.; rectified spirit, f ℥j; dissolve *Dose.* 15 to 50 drops as a febrifuge, (in intermittents.)

ALCOHOL DE QUININE. *Syn.* ALCOOL DE QUININE. TINCTURE OF QUININE. (*Majendie.*) *Prep.* Dissolve 6 grs. of sulphate of quinine in f ℥j of rectified spirit. *Dose, &c.* As the last. This tincture is principally used to prepare the wine of quinine.

ALCOHOL DE STRYCHNINE. *Syn.* TINCTURE OF STRYCHNINE. (*Majendie.*) *Prep.* Strychnine, 3 grs.; rectified spirit, f ℥iss; dissolve. *Uses, Doses, &c.* This tincture is given in paralysis, impotence, &c., in doses of 5 to 20 drops. It is a *violent poison.* (See STRYCHNINE.)

ALCOHOL DE VERATRINE. *Syn.* TINCTURE OF VERATRIA. I. (*Majendie.*) Veratria, 4 grs.; rectified spirit, f ℥j; dissolve. *Dose.* 10 to 25 drops.

II. (*Turnbull.*) For external use. Veratria, ʒj; rectified spirit, f ℥ij: dissolve.

Remarks. The first is given instead of colchicum, in gout, rheumatism, &c.; the second has been employed externally in neuralgia, as well as in gout and rheumatism, as a substitute for the ointment

ALCOHOLATES. Salts, in which alcohol appears to replace the water of crystallization. *Prep.* Some of them may be formed by simple solution and crystallization in alcohol. (Graham.)

ALCOHOLOMETER. An hydrometer or instrument for ascertaining the quantity of alcohol in any given mixture of spirit and water.

ALCOHOLOMETRY. The process or method of determining the strength of spirits.

General Remarks on the nature of Alcoholometry, and the Excise Regulations of Great Britain.—The great importance of being able *accurately* to determine the strength of spirits, in the United Kingdom, on account of the high duties levied thereon, has induced the government authorities, at various times, to fully investigate the subject. Towards the end of the last century, Sir C. Blagden instituted a series of very minute and accurate experiments to determine the real specific gravity of different mixtures of alcohol and water. The results of this investigation were published in the Phil. Trans. for 1790, and have formed the data from which the government have since made their calculations for the purposes of the Excise and Customs. More recently the Lords of her Majesty's Treasury requested the Royal Society to examine into the accuracy of these tables, and the construction and application of the instrument (Sike's hydrometer) now used by the revenue officers, and based thereon. The Committee of the Royal Society reported favorably of the accuracy of the numbers contained in Gilpin's Tables, employed by the government, which they declared far surpassed, in this particular, what could reasonably be expected, and that they were sufficiently perfect for all practical and scientific purposes. The experiments went to show, that the error introduced into calculations respecting the strength of spirits, by these tables, was quite unimportant in practice, and did not, in any one instance, amount to *unity in the fourth place of decimals.* This method, which I shall presently describe, adopts the sp. gr. as a test of the strength in alcohol, and is founded on the fact that the latter fluid is considerably lighter than water, and that (with proper corrections for condensation) the sp. gr. *regularly* increases or decreases, according to the relative proportions in which the two are mixed.

Several other methods of alcoholometry have been proposed, founded upon the temperature of the vapor; the heat evolved by the admixture with water; the insolubility of the carbonate of potassa in alcohol; the volatility of alcohol, &c. &c.; some of which I shall notice farther on. *The method adapted by the Excise and Customs* should be that employed in trade and commerce in England, not only on account of its superior simplicity and correctness, but for the purpose of *exactly coinciding with the survey of these authorities.*

The duties on spirits are charged on the number of *proof gallons* they contain, which is ascertained by first "*gauging*" or "*ullaging*" the liquor, and then taking its specific gravity, by Sike's hydrometer, the number indicated by which, on reference to the tables, gives the per centage of spirit it may contain *over* proof, or its deficiency per cent. *under* proof; and the real content per centage of proof, multiplied by the "gauge" or

"ullage," gives the net amount of proof spirit in the quantity surveyed.

The proof strength is an arbitrary standard, adopted for the purpose of facilitating calculations, for which it is well suited. The sp. gr. of proof spirit, as defined by Act of Parliament, is ·920 at 60° F., and contains, in 100 parts, by weight, 49 parts of alcohol of ·791, and 51 parts of water. At 51° F., 13 volumes of proof spirit weigh exactly equal to 12 volumes of distilled water. It is of great advantage to the spirit-dealer to be acquainted with the method of estimating the correct number of proof gallons in any sample or quantity of his commodities; and I have known many disagreeable errors result from ignorance on this point. Calculations of this kind are very simple and straightforward. Thus, when we find by the hydrometer that a given sample of spirits is 10 overproof, or "*o. p.*" as it is technically called, it means that 10 gallons of water added to 100 gallons of such a spirit, would produce 110 gallons of proof spirit; or, in other words, that 100 gallons of such a spirit contain exactly as much alcohol as is contained in 110 gallons of proof. In *overproof* spirit, the per centage overproof always represents the *quantity of water* it will take to reduce it to *proof*. By adding its per centage overproof to 100, we obtain a number, which, multiplied by any number of gallons, and divided by 100, will give the exact number of proof gallons which is contained in the given quantity of spirit of that strength. For example, I have a puncheon of rum, holding 91 gallons of spirit, which I find to be 21 *o.* p. How many proof gallons does it contain?

Per centage overproof 21, added to 100, equal to	121
Number of gallons	91
Divide by 100		11011
No. of gallons of proof spirit .	110·11

(To divide by 100, is only to point off the last two figures.) To ascertain how much water I must add to reduce it to the proof strength, I have only to deduct the number of gallons of 21 o. p. from its content in proof; in the above case this would be—

No. of proof gallons . . .	110·11
No. of gallons of the o. p. spirit .	91
Gallons of water to be added .	19·11

Or as nearly as possible 19 gallons and 1 pint. When we say a spirit is 11 u. p. or underproof, we mean that 100 gallons of such spirit contains 11 gallons of water and 89 gallons of proof spirit; and so of other strengths. By deducting the per centage underproof from 100, we not only obtain the number of proof gallons contained in 100 gallons of such a spirit, but as in the last case a factor which multiplied by any number of gallons, and divided by 100, gives the exact number of proof gallons contained in such a quantity of the given strength. Thus, I have an ullage brandy piece, containing 45 gallons of spirit, which I find by the hydrometer to be 10 u. p. How many gallons of proof does it contain?

Deduct 10 from 100, and we have	90
Multiply it by the No. of gallons	45
Divide by 100		4050
Quantity of proof spirit	40·50

Or exactly 40½ gallons.

On the same plan we may ascertain how much water it will take to reduce one strength to another, of any weaker degree. Thus, I have a puncheon of rum, as before, containing 91 gallons of spirit 21 o. p., which I wish to reduce with water to 10 u. p. I have already found that this quantity contains a little more than 110 proof gallons; I have therefore only to reckon how many gallons of spirit 10 u. p. it would take to contain an equal quantity of that strength. I find this by the simple rule of proportion. I know that 100 gallons are only equal to 90 of proof; therefore, if 90 are equal to 100, how many are equal to 110, which I find to be as nearly as possible 122¼ gallons. I have then only to deduct the number of gallons of 21 o. p. from 122¼ gallons to find the quantity of water I must add to make 122¼ gallons of spirit 10 u. p. By a little practice such calculations become excessively easy. In all these cases a knowledge of the four first rules of decimal fractions is advantageous, as the Excise calculate their proof to two figures of decimals or $\frac{1}{100}$ths. Their plan is to reject the *third* figure when less than 5, but to carry 1 to the preceding if it exceeds it; thus, 5·432 would be put down as only 5·43; but 5·437 would be written 5·44.

Formerly, spirit was said to be 1 *to* 3, 1 *to* 4, &c., overproof, by which it was meant that 1 gallon of water added to 3 or 4 gallons of such spirit would reduce it to proof. On the contrary, 1 *in* 3 or 1 *in* 4 underproof meant that the 3 or 4 gallons, as the case may be, contained 1 gallon of water and the remaining quantity of proof spirit. This method of calculation has now, however, given way to the centesimal system, which not only admits of greater accuracy, but is quite as simple, and should be adopted by every spirit-dealer in England, from being the plan followed by the Excise, with whose estimate it is absolutely necessary they should agree.

The stocks of "dealers" (who are not permitted to sell less than 2 gallons) are always taken by the proof; but the spirits sold by the retailers are only tested on being admitted into stock, and then afterwards taken according to their gross quantity, (ullage or gauge.) The Excise can, however, try the strength of any sample they choose, even in the stock of a *retailer*, when, if it be altered from the strength at which it was "*permitted*" into stock more than 3⅝, or if it be otherwise of an illegal strength, it becomes *seizable*. A surplus, however small, of more than 2 gallons over the quantity that should remain in hand of any one "*quality*" of spirit, after deducting the amount sent out by permits from the last stock, is also seizable; and even if an increase frequently occurs, though it be "*less than two gallons*," it immediately attracts the notice of the Excise, and frequently leads to *inquiries* and inconvenience to the dealer.

By the Revenue Laws of Great Britain, spirit of greater strength than 43 o. p., or sp. gr. 0·8597, is designated spirit of wine, and marked S. W. by

ACROLEINE. When fixed oils are exposed to a heat sufficient to produce ebullition, acroleine, mixed with carbureted hydrogen, is given off. By passing the vapor through a series of well-cooled bottles, partly filled with water; and by redistilling the contents of the second and third bottles, this substance will be obtained in the form of an oily liquid, possessing a very disagreeable odor. It has never been obtained in an isolated state, and little is known concerning its precise composition.

ADIPIC ACID. One of a series of new acids discovered by Laurent, among the products of the oxidation of oleic acid, by means of pure colorless nitric acid.

Prep. Gently evaporate the mother liquor, left from the process of preparing pimelic acid, set it aside for some days, and then collect the crystals deposited; repeat this operation until the liquor ceases to yield crystals. Then dissolve them in hot water, skim off the oil, filter, evaporate, and crystallize. Dissolve in ether, and evaporate to one half; collect the crystals and repeat the process a second time; next dissolve the two crops of crystals separately in alcohol, when adipic acid, in roundish crystalline grains, and dipic acid, in plates, will be obtained.

Prop. Color brown, soluble in hot water, volatile above 266°. It unites with the bases, forming salts called adipates, which are mostly soluble.

ADIPOCERE. *Syn.* Adipocera. (Adeps *Fat*, and Cera *Wax*.) Grave Wax. *Hist.* On the removal of the bodies from the Cimetière des Innocens in Paris, in 1786, it was found that they were for the most part converted into a substance resembling spermaceti, to which the name of adipocere was given. Fourcroy was the first who submitted this substance to a scientific examination, though it is said to have been previously known to grave-diggers, and that it is even mentioned by Lord Bacon.

App. It was proposed by Lavoisier to produce this substance artificially, for the purposes of the arts. Dr. Gibbs of Oxford found that lean beef, suspended in running water, was converted into fat (adipocere) at the end of a mouth. Three pieces of lean mutton were immersed in each of the three mineral acids, in separate vessels. At the end of three days, that in the nitric acid had changed into a soft fatty matter; that in the muriatic was less altered; while that immersed in the sulphuric had become black and carbonized. Attempts have been made to convert the dead bodies of cattle (carrion) into adipocere, for the purposes of the candlemaker and the soap-boiler, but without success. From the experiments of Von Harkhol, extending over a period of 25 years, it appears that the carcasses of mammalia, immersed in running water, are after a lapse of three years converted into a pure, hard, scentless fat, resembling white wax, perfectly fit for the manufacture of soap and candles. Exposure to stagnant water gives more fat, but of an impurer kind. For further information on this subject, the reader is referred to 'Ure's Chemical Dictionary,' and to the 'Dictionary of Arts, Manufactures, and Mines,' by the same author.

ADULTERATION. The fraudulent corruption of pure articles, by admixture with others of less value, for the sake of greater gain. The means of detecting the adulterations generally met with in trade, will be found explained, under each article of importance, in its alphabetical order.

ÆGIRINON. A once popular ointment, made by macerating the fruit of the poplar, in six times its weight of melted lard, and straining. It is much employed in some parts of the Continent.

ÆSCULINE. A new alkaline substance, said to have been found in the horse-chestnut. It is probably extractive matter combined with lime.

ÆTHIOPS. *Syn.* Ethiops. A name give by the older chemists to several black powders on account of their color. (See the following articles.)

ÆTHIOPS, ANIMAL. This was a powder obtained by burning various animals, as the hedgehog, mole, sparrow, &c., to a cinder.

ÆTHIOPS, ANTIMONIAL. *Syn.* Ethiops of Antimony. Æthiops antimonialis. *Prep.* Sulphuret of antimony, two parts; quicksilver, one part. *Proc.* Triturate until the globules are extinguished. *Dose.* 3 to 5 grs., gradually raised to a scruple, in some cutaneous diseases.

ÆTHIOPS, GOLDEN. *Syn.* Æthiops auripigmentum. This æthiops is made by triturating together the red sulphuret of arsenic and metallic mercury. It is poisonous, and is never employed in medicine at the present day.

ÆTHIOPS, JOVIALIS. Prepared by rubbing together equal parts of tin, quicksilver, and sulphur. It was once given in skin diseases.

ÆTHOGEN. A compound of nitrogen with boron, named from its combinations with the metals, producing a phosphorescent light, in the oxidating flame of the blow-pipe.

Prep. Mix seven parts of powdered anhydrous boracic acid, with nine parts of melon, place the mixture in a crucible lined with charcoal, and apply heat, then transfer the product into a well-stopped vial. (Balmain.)

Prop. A light powder, resembling magnesia, infusible, and nearly insoluble in water. It forms compounds with the metals, called æthonides. These may be prepared by either exposing a mixture of the metal and æthogen to heat, or a mixture of the cyanide of the metal with boracic acid

AGRICULTURE. (From *ager*, a field, and *colo*, I till.) The art or business of the farmer; the cultivation of the soil in large quantities, for the purpose of raising crops and live stock. In its more extended sense, it includes *road-making*, *embanking*, *draining*, *planting*, *&c*. It is one of the most important of the useful arts, and when combined with chemistry is not unworthy of the name of science. The following short sketch of the history and principles of agriculture is from the pen of J. C. Loudon, F. L. S., H. S., &c.

Hist. "*The origin of agriculture* may be traced to remote antiquity, and was doubtless coeval with that of fixed property. In the primeval state of society, the sole riches of the husbandman consisted of flocks and herds, which were kept in a state of movement from one point to another, in search of pasturage and water; but as population increased, mankind adopted a fixed abode; this could only be done by bestowing on the site a certain degree of labor and care, which became as it were the *price paid* for constituting it *private property*. At this point in the progress of civiliza-

tion, agriculture may be said to have commenced. Previously, the natural products of the soil were merely consumed where they were found, but *now* men sought to increase them by culture.

"*The culture of land* will be found to have depended in every country principally on its climate and civilization; though partly also on its government and population. In the warmer climates, where nature produces fruits in the greatest abundance, for the food of both men and animals, and where very little care is required to procure shelter or clothing, agriculture has made but little progress; because it is comparatively unnecessary for the prosperity of the inhabitants. In climates of a directly opposite character, agriculture has made equally slight progress, from the natural obstacles opposed to it. In such countries, for example, as Greenland and Kamschatka, only one or two kinds of corn crops can be cultivated, and perennial grasses can scarcely exist; because the ground is covered with snow for eight months of the year; and in these countries agriculture is but little practised, as the chief resources of the inhabitants for food are found in the sea and forest. In intermediate climates, such as those of South Britain, the middle of France, and the North of Italy, the soil may be labored by man throughout the whole year, and there is scarcely any limit to the kind of crops which may be raised on it. In such climates, agriculture is calculated to attain the highest degree of perfection; and comparing different parts of the zones of this description of climate in both hemispheres, perhaps it may be asserted, that *the best agriculture in the world is to be found in Britain and the North of Italy;* viz., in *East Lothian* and *Norfolk*, in the *Vale of Arno* and on *the banks of the Po.* The kind of agriculture practised in different countries is also of course adapted to the difference of climate. Thus, towards the North Pole, the great art of the cultivator would be to increase the heat; or, rather, in adopting such measures as would best guard plants and animals against cold, rains, and the vicissitudes of the weather. Towards the south, on the other hand, the art of the cultivator would be chiefly directed to moderating the extreme heat and supplying moisture. It thus appears that the agriculture of any country depends on its latitude; and that in high and low latitudes, where there are greater extremes of climate and temperature to contend with, agriculture must be of a more difficult and hazardous description than in intermediate or more temperate climates, such as that of Syria, where the art is supposed to have originated, or in Europe, where it may be considered as having attained its highest degree of perfection.

"In tracing the progress of this art in civilized countries, we have only to follow the chronology of general history. As the Greeks and Romans appear to have arrived at as great a degree of perfection in legislation as the moderns, so they appear to have attained nearly equal excellence in the practice of agriculture. Till within the present century, very little difference existed between the most approved agriculture of climates analogous to that of Italy, and the agriculture of the Romans as described by Cato, Columella, and other ancient writers. The chief superiority of the moderns consists in their machinery, and in their knowledge of the *science* of the art; the last being of very recent date, and by no means general among practitioners, (farmers.) By science, improved breeds both of plants and animals have been originated, and by modern machinery a more perfect tillage has been produced, and also a more complete separation of the produce from the soil, from the refuse of the plants which bore it, and from all impurities.

"*The history of British agriculture* begins with the Roman Conquest. Julius Cæsar found the inhabitants in a state of semi-barbarism; but Agricola left them in possession of all the arts of civilization then known. Agriculture declined with the invasion of the Saxons; but was preserved through the dark ages after the establishment of Christianity by the intelligence of the religious establishments, who gradually became possessed of the greater portion of the landed property of the country. Agriculture revived in the reign of Henry VIII., and in that of Elizabeth, during the long peace which then prevailed, and the consequent security of property; and it afterwards declined during the civil wars; it again revived during the reigns of William and Mary, Queen Anne, and George I., in consequence of the introduction of the Flemish husbandry, which included the culture of turnips and clover. A still greater stimulus to the art was given during the reign of George III., by the introduction of ploughs drawn by *two* horses, instead of *four* or *six;* of the drill system, and its application to the culture of turnips and potatoes; and by the improvements made in the breeding and rearing live stock, by Bakewell and Culley. Early in the present century, the threshing-machine was an important addition to agricultural machinery; the reaping-machine, the frequent drain system, and the subsoil plough, are improvements just coming into use; and the next grand attempt will probably be the general application of steam, instead of horses and cattle, in tillage and other field operations.

"*The principles of agriculture* are derived from a knowledge of the nature of plants and animals, of soils and manures, and of the climate, the seasons, and the weather. Plants are organized beings, which take up their food by means of roots, from the interior of the soil;* animals are organized beings, which select their food from vegetables growing on the surface of the soil, or from other animals, and this food is prepared before being absorbed into their system, by means of a stomach. The climate of a country determines both the plants and the animals which can be produced in it; and the seasons and the weather, the times when the plants and animals of the given climates are in particular states of vigor or torpidity; and when certain operations of culture can be performed on them or on the soil.

"The nature of these elementary materials being understood, even though imperfectly, certain improvements can be effected in them by art, which are greatly conducive to the increase of agricultural produce. The kinds of plants and animals suitable to any given climate, soil, or season, are determined by the laws of nature; but from among these kinds it is in the power of man to

* And by means of their leaves from the atmosphere.—A. J. C.

Table exhibiting the relations between the Indications of Sike's Hydrometer and the real Specific Gravity. By Mr. Gutteridge.

Other instruments of a similar nature to Sike's hydrometer (but less complicated) have been constructed, which at once give the per centage of alcohol in a given sample. Thus, the areometer of Gay Lussac, and the alcoholometer of Tralles, at once float to a figure on the stem, which indicates the per centage of alcohol, *by volume*, in the liquor in which they are placed; while the alcoholometer of Richter gives *at once* the per centage by *weight*.

II. *From the specific gravity to find the per centage of pure Alcohol, by volume. Proc.* The sp. gr. at 60°, having been ascertained by any of the usual methods, (see Specific Gravity,) must be sought for in the *second* column of the following table, against which will be found, in the *first* column, a number representing its per centage of alcohol of 0·7939.

Table exhibiting the per centage by volume of Alcohol, corresponding to any given Specific Gravity. By Tralles.

Alcohol in 100 Measures of Spirit.	Specific Gravity at 60° F.	Difference of Specific Gravity.	Alcohol in 100 Measures of Spirit.	Specific Gravity at 60° F.	Difference of Specific Gravity.	Alcohol in 100 Measures of Spirit.	Specific Gravity at 60° F.	Difference of Specific Gravity.

Use of the preceding Table. When the temperature of the spirit is 60° F., the first column of the table gives at *once* the per centage of alcohol by *measure; when the temperature is below* 60° an addition must be made of 1 measure per cent. for every 5 degrees of the thermometer; and when above 60° a like quantity must be deducted. This correction will amount to the fraction $\frac{1}{5}$ or the decimal ·2 for every single degree, and is very easily made. *If the specific gravity sought* cannot be found exactly in the table, the *difference* between it and the next greater specific gravity in the table must be taken, which will give the numerator of a fraction, having for its denominator the number found in the *third* column against the next greater number just employed. This fraction, added to the per centage of alcohol in the first column of the table against the said specific gravity, will give the true per centage sought. Thus: "if the specific gravity of a spirituous liquor is 9605, what is its alcoholic content?" Here 9605 is not in the table, but the

next greater number is 9609; I therefore deduct the former from the latter, and put the difference (4) as the numerator of the fraction, having for its denominator (13), the number in the column of differences against 9609; I then add the fraction $\frac{4}{13}$ so found to the per centage against 9609 in the first column, which gives $33\frac{4}{13}$ as the true per centage of alcohol in the given sample.

The per centage by weight may be found in an equally simple way: multiply the number of volumes per cent. by ·7939, (the specific gravity of pure alcohol,) and divide the product by the specific gravity of the sample, the quotient will give the number of pounds of alcohol in 100 lbs. of the given spirit. Thus: in spirit of 9609 I find there are 33 *volumes* of alcohol per cent., what is its per-centage by weight? Example:

Sp. gr. alcohol	7939
Volumes of alcohol per cent. in sample . . }	33
Sp. gr. of sample 9609		261987 *product.*
	27·28 } or 27¼ lbs. of alcohol per cent.

III. *From the specific gravity to ascertain the per centage of alcohol by weight.* When it may be inconvenient to perform the short calculation just explained, the per centage by weight may be ascertained by mere inspection of the following table.

TABLE by LOWITZ, showing the Acoholic Content, by WEIGHT, of Spirits of different Specific Gravities, from pure Alcohol to pure Water, at 60° and 68° F.

Remarks. This table is exceedingly useful in chemical calculations, and in purchasing spirit of high strength, which is usually sold by weight.

IV. *From the temperature of the vapor to determine its alcoholic contents.* This method has been proposed by Gröning, and offers a ready means of approximating to the strength of the spirit passing over, at every part of the process of distillation, as well as the value of the wash left in the still. *Oper.* Thrust the bulb of a thermometer through a cork inserted in a tube fixed in the head of the still, or other vessel, and note the

* Alcohol of the Lond. and Dub. Ph. † Rectified spirit of the L. Ph. ‡ Proof spirit.

temperature of the vapor in which it is thus immersed. Against this number in the following table, will be found the alcoholic contents of the vapor, and in the next column that of the boiling liquid from which it has arisen.

TABLE, by GRÖNING, of the Alcoholic Content of the vapor from mixtures of alcohol and water, and also of the boiling liquid from which they have been disengaged.

Temperature of Vapor. Fahrenheit.	Alcoholic Content of Vapor by volume per cent.	Alcoholic Content of boiling liquid per cent.

V. *To determine the alcoholic contents of wine, beer, &c.* *Proc. a.* Half fill a graduated tube with the liquor to be tried, and add thereto about 12§ or 15§ of solution of diacetate of lead, (see below,) then agitate the mixture until the color be nearly removed; powdered dry carbonate of potassa must be next added until it falls down undissolved, on shaking the liquid; after which, on allowing the tube to repose for a short time, the alcohol will be seen floating on the top of the aqueous portion in a well-marked stratum, and its quantity may be read off by means of the graduations on the tube.

The solution of lead. *Ing.* Powdered litharge, 2 oz.; sugar of lead, 3 oz.; water, 1 pint. *Proc.* Boil to one half in a glass or lead vessel, then put it into a bottle, and cork it close.

b. The same may be effected by agitating a little powdered litharge with the sample until it becomes discolored and limpid, when it may be saturated with carbonate of potassa as before.

c. Another good way to determine the quantity of alcohol contained in a given sample of wine, is to separate it from the non-volatile constituents by distillation. A very neat apparatus for experiments of this nature has been contrived by M. Gay Lussac; but any species of small still or retort may be employed for the purpose. You take three hundred parts of the liquor to be tried, measured in a graduated glass tube. The operation is equally adapted for wines, beer, gin, and all kinds of spirituous liquors. Having inserted the liquor into the still, you carefully and slowly distil over one hundred parts, or one third of the liquor in the still, making use of a graduated tube as the recipient, and stopping the operation when the distilled liquor reaches the hundredth degree. You then ascertain the alcoholic strength of the distilled liquor by means of the hydrometer, and dividing the result by three, you have at once the per centage of alcohol of the liquor submitted to examination. If, for example, the hundred parts of distilled liquor contain thirty parts of alcohol, the wine submitted to distillation contains ten per cent. of alcohol. But if, from want of attention, you distil over more than one hundred parts of the liquor, it will not do to divide the alcoholic strength of the product by three, to obtain the per centage of alcohol of the liquor submitted to distillation: you must employ as the divisor, the number which expresses the relation of the volume of the distilled product to the bulk of the wine. If, for example, you have one hundred and six parts of distilled liquor, containing (as ascertained by the hydrometer) thirty-three parts of alcohol, you divide three hundred by one hundred and six, which gives 2·83, and then divide thirty-three by 2·83, which gives 11·66. The last number expresses the per centage of alcohol of the liquor submitted to examination.

Remarks. It was at one time maintained by Fabroni and others, that alcohol does not exist in the fermented liquors from which it is procured by distillation, but is, like the essential oils of almond and mustard, formed during that process. The first two of the above processes will, however, clearly demonstrate that such is not the case. The process *a* was first employed by Brande; the process *b* by M. Gay Lussac. The latter chemist has also distilled wine in vacuo at 59° F., and alcohol came over.

Concluding Remarks. Several other methods of alcoholometry have been adopted at various times, besides those just noticed, but the majority have little merit for accuracy, and are therefore quite inapplicable to the purposes of trade in this country. Formerly the strength of spirit was estimated by what was called the "*proof*." A little of the spirit was poured upon a small quantity of gunpowder, in a spoon or saucer, and inflamed; if explosion of the powder followed the combustion of the spirit the sample was said to be above or over proof, but if the contrary, it was declared below or under proof. Hence arose the words proof and proof spirit, which have since been applied to spirit of particular strength by Act of Parliament. *Another method*, is the "preuve d'Holland" of the French, or the *bead* still frequently employed by persons unacquainted with the use of the hydrometer. It consists in shaking the spirit in a vial, and observing the *size*, *number*, and *duration* of the bubbles or "beads," as they are called. The *larger* and *more numerous* these are, and the *more rapidly* they *break* and *disappear*, the *stronger* is deemed the spirit. This method, like the last, can but at best afford a mere approximate idea of the strength of spirits,

while it is liable to be influenced by circumstances, which will affect the sp. gr. in only a very trifling degree. Thus the addition of a little sugar to the spirit, barely sufficient to lower the hydrometer one degree, will sometimes give to a weak sample the appearance of one many degrees stronger. The gunpowder test is even more fallacious, for if one spoonful of a given spirit be just sufficient to fire the powder, *double the quantity* of a spirit 20§ stronger will *fail* to do so. Love's beads are often employed to ascertain the strength of spirit. (See SPEC. GRAV.) The *sudden increase of temperature* produced by mixing a given weight of the spirit with a given weight of pure water being observed by a thermometer has also been proposed for the same purpose, but neither this nor the last method is capable of *great accuracy*. The latter plan would require for its application a series of tables based on experiments which we do not however possess.

Before concluding this imperfect memoir on alcoholometry, I think I cannot better consult the interest of those connected with the spirit trade than by giving them the following important table. It shows by mere inspection the variation in the "richness in alcohol," and in volume, which spirits undergo by change of temperature. Persons purchasing spirits during summer, and paying for them according to their apparent quantity and strength, will lose considerably when the weather becomes colder, without being conscious of such loss from the hydrometer. By the inspection of this table the corrections to be made for change of temperature will become apparent.

TABLE exhibiting the Volume which 1000 gallons of Spirits of different strengths, measured at the given temperatures, will have when measured at 59° F., arranged from GAY LUSSAC's Tables to his Alcoometre, and adapted to Fahr. Scale by Mr. COOLEY.

Pure Alcohol by volume, per cent.	Number of gallons which 1000 gallons of spirit at the given temperatures will measure at 59° Fahrenheit.

ALDEHYDAMMONIA. A compound of carbon, hydrogen, oxygen, and nitrogen, discovered by Doebereiner and Liebig.

Prep. Sulphuric acid 6 parts; water 4 parts; alcohol, of 80%, 4 parts; hyperoxide of manganese in fine powder, 6 parts. *Proc.* Dilute the acid with the water, then carefully add the alcohol, and next the manganese; agitate and distil with a gentle heat, from a spacious retort into a receiver surrounded with ice, and connected with the former perfectly air-tight. When six parts have distilled, re-distil this portion from its own weight of dried muriate of lime, until three parts have come over, which must be again rectified in the same manner, until 1½ part of liquid is obtained in the receiver. This liquid must then be mixed with an equal bulk of ether, and the mixture saturated with dry ammoniacal gas; brilliant colorless prismatic crystals will then form, which, after washing with ether and drying, are pure aldehydammonia.

Prop. &c. Smells like turpentine; melts at 160°; volatilizes, unchanged, at 212°; decomposed by exposure to the air; soluble in most menstrua except ether. *Use.* To make aldehyde.

ALDEHYDE. *Syn.* Hydrate of Oxide of Acetyle. A compound of carbon, hydrogen, and oxygen. Discovered by Liebig.

Prep. Dissolve aldehydammonia in an equal weight of water; place the solution in a retort, and add rather less than an equal quantity of sulphuric acid, diluted with about half its weight of water; then distil as above. Rectify the product twice from its own weight of dried muriate of lime, at a heat not exceeding 86° Fahr.

Prop. An ethereous liquid, boiling at 72°; neutral, inflammable, mixes with water, alcohol, and ether; decomposed by exposure to the air, into liquid acetic acid; spoils by age.

ALDEHYDIC ACID. *Syn.* Acetylous Acid. Lampic Acid. An acid not perfectly known, but supposed by Liebig to be the lampic acid of Davy and Faraday, or at least its essential part.

Prep. Digest oxide of silver in aldehyde, decant and pass sulphureted hydrogen through the liquid to throw down the silver. The product is a weak acid, forming salts called aldehydates with the bases. These salts suffer decomposition during the evaporation of their solutions, and hence cannot be obtained in the dry state.

ALE. *Syn.* Barley Wine. Ala. Cerevisia. A pale-colored liquor, brewed from lightly-dried malt. It is usually described as containing more saccharine matter and mucilage than beer or porter; but this is not a characteristic of the finer kinds of ale, as *Old Burton, Scotch, East India*, and other varieties, that have undergone a thorough fermentation. *New* or *mild ale*, on the contrary, abounds in undecomposed sugar and gum, and is thus rendered more nutritious, though less alcoholic, than the above varieties.

Process of brewing ale. The various operations of brewing are nearly the same for every species of malt liquor, the differences in the products arising from the materials employed, the heat of the water used for mashing, and the temperature at which the fermentation is conducted. (See Brewing.) For ale, pale or lightly-dried malt should be chosen, as well as pale hops, if it be desired to brew a liquor possessing but little color; and the fermentation should be carried on at a low temperature. Almost every county in England has its variety of ale, but the difference consists chiefly (the same quantity of malt and hops being used) in the preparation of the malt. The water may in some cases vary in quality, the boiling may be longer or shorter, or the liquor may be turned on at a different heat; but these circumstances being considered, one general process serves for the whole, as before observed. For immediate use, the malt may be all pale; but if brewed for keeping, or in warm weather, one-fourth should be amber malt. 6 lbs. of Kent hops should be used to the quarter, or 8 to 10 lbs. for keeping ale. The stronger ales contain about 8% of absolute alcohol; ordinary ales from 5 to 6%.

ALE, BARNSTAPLE. Boil the water, then throw two pails of cold water into the mash tun, and afterwards the boiling water; then immediately put in the malt, half a bushel at a time. After stirring it till it is soaked, cap it with malt or bran, cover it close, and let it stand three hours; then see if the mash is sunk in the middle; if so, it must be filled level with boiling water, to stand half an hour; when it should be run off in a goose-quill stream, and be returned upon the grains, by a bowl or pailful at a time, as far back as possible from the cock, until the liquor strains through the body of the grains, and at last comes very fine; otherwise the thick parts are forced

down to the cock. This is called "doubling;" continue to do so for half an hour, then stop, and let it stand half an hour longer in winter, but not in summer. Then rub four pounds of hops very fine into the sieve, for the wort to run through; do not draw it off too near before lading over more boiling water out of the copper. This is to be continued until the whole quantity of ale wort is obtained, which, with all the hops, is to be boiled till the liquor breaks or curdles. Now empty all into large tubs or coolers; work, when cold, with the same hops altogether, thus: put a little yeast, and that not a day old, to a quantity, and mix that with the rest, to work 12 or 14 hours, and then strain it directly into the barrel, where keep filling it until it has done working.

ALE, BAVARIAN. This is a beer which has been made to ferment at a low temperature, until all the substances which favor acetification have been rendered insoluble. The fermentation is conducted in wide, open, shallow vessels, which afford free and unlimited access to atmospheric oxygen, and this in a situation where the temperature does not exceed 46° to 50° Fahr. A separation of the nitrogeneous constituents, *i. e.*, the exciters of acidification, takes place simultaneously on the surface and within the whole body of the liquid. The clearing of the fluid is the sign by which it is known that these matters have separated. The beer obtained in this way is invariably far superior, in quality and stability, to that brewed according to the common method. (Liebig.) To be enabled to keep the temperature at the proper point, the operation is conducted in a situation removed as much as possible from the influence of atmospherical changes of temperature, and at such seasons as are favorable to the same.

ALE, BURTON. This is a strong species of ale, of which only a barrel and a half is drawn from a quarter of malt. Temperature for the *first* mash 170°, and for the second 180°, followed by a mash for table beer at 165°. It is tunned at 58°, and cleansed at 72°. The finest pale malt, ground two days before using, together with the best Kent hops, (6 to 8 lbs. per quarter,) are employed for this ale. *Remarks.* The "East India" ale, brewed by Bass & Co. of Burton, is perhaps as near an approach to wine as malt liquor is capable of receiving; it is indeed the "wine of malt."

ALE, DORCHESTER. This is made with ½ pale and ⅓ amber malt, with 6 or 7 lbs. of hops to the quarter. The temperature of the first mash is 170°, and of the second 180°; boiled for 30 minutes, and the yeast added, when a head gathers on the gyle-tun; work until the head begins to fall, then cleanse and fill up the casks as long as they continue to work. Two barrels per quarter.

ALE, EDINBURGH. Employ the best pale malt. 1st. Mash two barrels per quarter, at 180°; mash three quarters of an hour, let it stand 1 hour, and allow half an hour to run off the wort. 2d. Mash 1 barrel per quarter, at 183°; mash three quarters of an hour, let it stand three quarters of an hour, and tap as before. 3d. Mash one barrel per quarter, at 170°; mash half an hour, let it stand half an hour, and tap as before. The first and second wort may be mixed together, boiling them about an hour or an hour and a quarter, with a quantity of hops proportioned to the time the beer is intended to be kept. The first two may be mixed at the heat of 60° in the gyle-tun, and the second should be fermented separately for small beer.

Remarks. The best hops should be used, in the proportion of about 4 lbs. for every quarter of malt employed.

ALE, ESSEX. This ale is brewed by putting boiling water into the mash-tun, and adding thereto some cold water, and then the malt, gradually, until a cover of dry malt is left on top; it is then allowed to stand three hours; in the mean time a similar mash is made with half the previous quantity of malt, and the same measure of water, in another tun, as soon after the first as possible; both worts are drawn off simultaneously, and the latter serves as a second water for the malt used for the former. The smaller quantity of malt is then mashed a second time with water. The first wort is boiled an hour, or until it breaks into large flakes, when half of it is taken out, and the remaining raw wort added to it, and the boiling continued until it again *breaks*. The wort is now drained off from the grains and boiled, and a fresh mash made with the wort from the second tun, for the larger quantity of malt, and very hot water for the other; after an hour it is drawn off, and another mash made for small beer. The proportion of hops is 2½ lbs. per quarter. This system of mashing, which has no advantage over the usual way, has been called "succession mashing."

ALE FOR PRIVATE FAMILIES. A bushel and three quarters of ground malt and a pound of hops are sufficient to make 18 gallons of good family ale. That the saccharine matter of the malt may be extracted by infusion, without the farina, the temperature of the water should not exceed 165° or 170° Fahrenheit's thermometer. The quantity of water should be divided into two portions, one of which should be poured upon the malt as speedily as possible, and the whole being well mixed together by active stirring, the vessel should be closely covered over for an hour; if the weather be cold, for an hour and a half. If hard water be employed, it should be boiled, and the temperature allowed, by exposure to the atmosphere, to fall to about 165° Fahr.; but if rain water is used, it may be added to the malt as soon as it reaches the point. After standing the proper time, the wort must be drawn off into another vessel, and the second portion of the water poured on, which should be allowed to mash an hour. The first wort may then be boiled with ½ lb. of hops for one hour, by which time the second mashing will be ready to be drawn off, and should be boiled for half an hour, with ½ lb. of fresh hops. The two liquors should now be mixed and cooled down to the temperature of 60° or 65°, when a pint of good thick yeast should be well stirred in, and as soon as the fermentation is completed, the liquor may be drawn off into a clean cask previously rinsed with boiling water. When the slow fermentation which will ensue has ceased, the cask should be loosely bunged for two days, after which, if the liquor be left quiet, the bung may be properly fastened.

Pale malt is the best, because, when highly dried, it does not afford so much saccharine matter. If the malt be new, it should be exposed to the air, in a dry room, for two days previously to its being used. A third mashing may be made for table beer.

ALE, LONDON. I. Pale malt, 14 quarters; hops, 112 lbs.; mash with 28, 18, and 18 barrels of water; boil with the hops, cool, and set with 36 lbs. of yeast; cleanse with salt, 3 lbs. *Prod.* 34 barrels, or 1⅓ gallon for each gallon of malt employed.

II. (*To brew two barrels from a quarter of malt.*) Turn on two barrels at 175°; mash one hour, and let it stand for the same time. For second mash, turn on one barrel at 160°; mash one hour, and stand one hour: boil the first wort briskly for one hour; and boil the second two hours, or till the whole is two barrels. Cool down to 60°, and tun. Cleanse on the fourth day at 72°, previously mixing in 2 ounces of ginger, ½ an ounce of salt, and a handful of flour. Keep the working tun closely covered, and just before the head begins to fall, skim the top, and rouse in the rest. When the blebs are large and on the fret, rouse in ½ an ounce of salt, a handful of malted bean-flour, and some fresh yeast, after which it will ferment more kindly, and the cleansing may soon follow, with the new head on. Take care to fill up the casks while working, and before bunging put a handful of scalded hops into each.

ALE, NOTTINGHAM. This is usually brewed by three mashings in the common way, but a much longer time is occupied in the mashing, and after drawing off each wort, the grains are washed by pouring over them fresh water from the copper, by two or three bowlfuls at a time. The boiling is conducted in separate portions for each wort, and the hops, enclosed in a coarse canvass bag, are only allowed to boil for half an hour, when they are taken out, and the boiling continued until the bubbles break into little ragged particles. The quantity of hops is divided between the boilings, and frequently the second and third worts are boiled together.

ALE, RINGWOOD. This brewing produces two barrels and a half from the quarter. The best pale malt and pocket hops are used, at the rate of 6 lbs. to the quarter. Turn on first mash at 180°, and second mash at 190°. Pitch the tun at 60°, and cleanse at 80°. Mash successively one hour, and three quarters of an hour, standing an hour and a half, and two hours. Add in the tun 2 lbs. of yeast for every barrel, and coat with salt and flour after the first skimming.

ALE, SCOTCH. This ale is brewed from the finest pale malt, (made from the best English barley,) and the best *East Kent Hops*, or for long keeping, *Farnham's* or *Country's*. The brewing is restricted to the colder portions of the year, as it never succeeds so well during the months of May, June, July, August, and September. Only *one mash* is made, and that at a temperature of about 180°, with one-third of the quantity of the water necessary for the brewing. The mash-tun is then covered up for half an hour, when the wort is drawn off, and a quantity of water, at the same temperature as before, sprinkled uniformly over its surface. This is performed by throwing the water into a vessel with a bottom full of holes, somewhat resembling a shower-bath, from whence it descends and gets equally distributed over every portion of the malt. After an interval of about twenty minutes, this wort is drawn off from several small cocks or holes, placed round the circumference of the bottom, by which means the hot water is made to percolate equally through every particle of the mass. This operation, called "sparging," is performed a second time, with a fresh portion of hot water, and after a like interval, is again drawn off. This process is repeated several times, until the density of the mixed worts becomes adapted to the quality of the ale required Usually eight or ten "spargings" are employed, the latter at about 5° or 10° cooler than the first The skilful brewer so divides his water that it may produce a wort of the proper gravity; but when a very strong one is required, the latter "sparges" are used for table beer, or as water for mashing a fresh quantity of malt. In this way, 1 quarter of malt will yield full 81 lbs. of extract. The wort is next boiled, with 4 lbs. of hops to every quarter of malt, and afterwards cooled down to 50° before adding the yeast. The latter must not exceed half a gallon for every 100 gallons of wort. The fermentation now commences and proceeds slowly, and in some brewings is accelerated by rousing up twice a day. Should more yeast be absolutely required in a few days, a *little* may be added. The fermentation generally continues for 15 to 20 days; and the ale is not cleansed before the degree of attenuation does not exceed ¼ lb. per diem, and not more than ¼ of the original gravity of the wort remains. This process is then performed by drawing off without skimming. As soon as the fermentation is finished, the ale is put into carefully prepared casks, and stored in a cold cellar. Here it soon becomes fine, and seldom wants racking before sale. The usual gravity per barrel of the best Scotch ale is about 38 or 40 lbs., and is seldom lower than 32 lbs. or higher than 44 lbs.

ALE, TABLE. This is usually made by mashing the grains after the wort for the strong ale or beer has been drawn off; but if a separate brewing be made, the following are good proportions:— Pale malt 1 quarter; mash with 4, 3, and 2½ barrels of water; boil with 5 lbs. of hops, set with 1 gallon of yeast, and cleanse by beating the head in and letting it work out. *Prod.* 8½ barrels, or full 4 gallons of ale for 1 of malt.

ALE, WELSH. Take 3 quarters of the best pale malt and 25 lbs. of hops; turn on the first liquor at 178°. Mash for an hour and a half, and stand two hours. Turn on second liquor at 190°, and stand two hours. Boil an hour and a half; pitch the tun at 62°, and cleanse at 80°, using salt and flour. After the second mash, turn on for table beer at 150°. Mash three quarters of an hour, and stand two hours.

ALE, WHITE, (DEVONSHIRE.) Boil together 12 gallons of pale ale-wort, 1 handful of hops, and 4 or 5 lbs. of grouts; cool, and add of yeast 3 lbs When it is in a state of lively fermentation, bottle in strong stone half-pints; well cork them down, and wire them. *Remarks.* This is much drunk in some parts of Devonshire. It effervesces when opened.

ALE, WINDSOR. This ale is brewed from

the best pale malt and hops. Turn on the first water at 180°; mash 1½ hour, and stand 1 hour; boil 1 hour. Turn on the second liquor at 190°; stand ¾ of an hour; boil 3 hours. Turn on the third liquor at 165°; mash ¾ of an hour; stand ¾ of an hour. Pitch the tun at 60°; cleanse at 80° on the third day. Skim as soon as a close yeasty head appears, until the yeast ceases to rise, then rouse in ½ lb. of hops per quarter.

ALE, YORKSHIRE OAT. The malt used is made from oats of the white sort, and dried with coke. Mash 1 quarter of ground malt with 44 gallons of cold soft water, and let it stand 12 hours; then draw off the wort, and infuse therein for 3 hours 2 lbs. of hops, well rubbed between the hands; next strain; tun it, and work it briskly with yeast for two or three days; cleanse, and in ten days it will be fit to bottle. It drinks very smooth, brisk, and pleasant, but will not keep. It looks very much like white wine.

ALIZARINE. *Syn.* PURE MADDER RED. *Prep.* I. Expose madder red to a gentle heat, when the alizarine will sublime, and may be collected.

II. Add powdered madder cautiously to its own weight of oil of vitriol, and mix with a glass rod; then wash the charred mass with clean cold water; dry, and sublime as before.

Prop. Orange-red crystals, very soluble in alkaline solutions, which it colors violet; dyes mordanted cloth red. *Remark.* The name is derived from Ali-zari, the commercial name of madder, in the Levant.

ALKALIS. (From the Arabic *al*, an essence, and *kali*, the plant from which soda was first obtained.) Substances which possess the property of forming salts with the acids, and for the most part of turning the vegetable blues to greens, and yellow turmeric paper *brown*. The principal alkalis are *soda*, *potassa*, and *ammonia*. The *first* has been called the *mineral*, the *second* the *vegetable*, and the *third* the *volatile* alkali; but this distinction is now nearly obsolete. Soda and potassa have also been called the fixed alkalis, from their permanence in the fire.

Hist. At the time when Lavoisier declared oxygen to be the universal acidifying principle, Morveau conjectured hydrogen to be the alkalifying principle; but it was afterwards demonstrated by Sir H. Davy, that potassa and soda are actually the oxides of the metals, potassium and sodium. Ammonia is a compound of nitrogen and hydrogen. Dr. Murray conceived that either hydrogen or oxygen might generate alkalinity, but that a combination of the two was necessary to give this condition in its utmost energy. This theory is not, however, borne out by the observed phenomena of chemistry. Gay Lussac conceives alkalinity to be the result of "the alkalifying property of the metal, and the acidifying property of the oxygen, modified both by combination and by the proportions;" but this "coalition" theory is far from satisfactory. Of late years the list of alkalis has been greatly extended by the discovery of several vegetable principles possessing important properties and forming salts with the acids. (See ALKALOIDS.)

Prop., Char., &c. Potassa, soda, and ammonia, are known by the following characteristics:—An acid urinous taste; a great degree of causticity; turning vegetable blues green, and yellows brown; forming soaps with the fixed oils; solubility in water, and when pure in alcohol; forming salts with the acids; solubility of their carbonates; action of their carbonates on vegetable colors.

Caution. The pure or caustic alkalis should be kept in glass bottles, well secured from the air, as they rapidly absorb carbonic acid and become carbonates.

ALKALIMETER. A measurer of alkalinity.

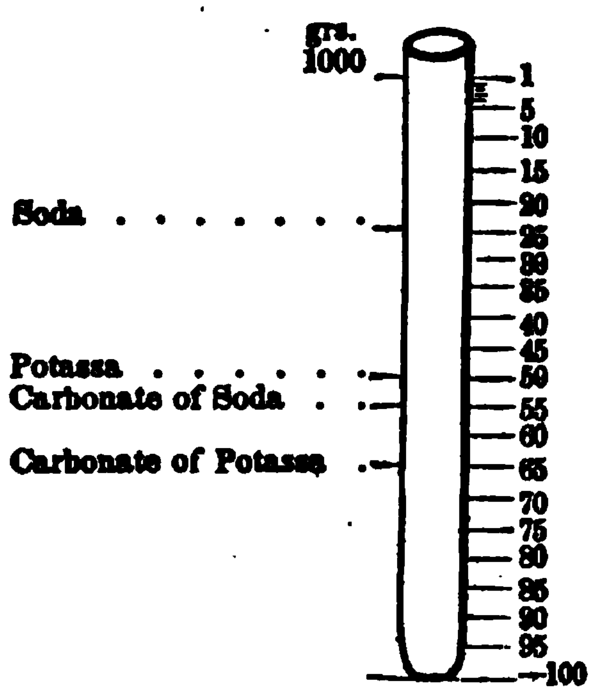
ALKALIMETRY. The art or method of determining the amount of pure alkali contained in any given sample.

Remarks on the principles of alkalimetry, &c. The common method of alkalimetry is founded on the known quantity of pure alkali, which is required to saturate a given weight of dilute sulphuric acid. The glasses, or alkalimeters, as they are called, with which the operation is performed, are usually graduated into 100 parts, for the purpose of exactly estimating the quantity of acid employed. As the sulphuric acid, however, acts upon the muriates and sulphurets usually present in the alkalis of commerce, this plan does not admit of great accuracy, unless proper precautions are taken to avoid the source of error. Some years ago the German soap-boilers estimated the strength of their ashes by merely pouring a quart of water on a pound of the former, and then putting in a piece of Dutch soap, added water, in small portions at a time, until it sank. The more water required to effect this object, the richer the ashes were supposed to be in alkali. This plan was also employed at no very distant period in some of the remoter parts of the United Kingdom. Alkalimetry has lately engaged the attention of some eminent chemists, and by following their suggestions, the "richness" of any sample of ashes, barilla, or alkalis may be obtained with great precision. The importance of this subject to the soap-maker and manufacturing chemist must at once be evident. The following are among the most approved methods of procedure.

I. *Oper.* Pulverize a little of the sample, and weigh therefrom exactly 100 grs., agitate it with about half an ounce of hot water in a vial or small tube, then allow it to settle, and pour off the clear into another tube or vial; repeat the process with a second and third portion of hot water, or until nothing soluble remains, observing each time to allow the liquid to settle before pouring it off; the mixed liquid is then tested as follows:—the test acid described below is poured into the glass tube until it reaches exactly to the line marked by the name of the alkali under examination; water is then poured in to the line marked 1 or 1000, and the whole is well mixed by placing the thumb on the orifice of the tube and shaking it well. The measure of this dilute acid must then be carefully observed, and water added to make up the proper quantity as before; should it be lower than the mark, agitation being again employed. The test liquor thus prepared is then to be *carefully* added to the solution of the alkali just described until it be *perfectly neutralized*. The quantity of the test liquor used must next be read off from the graduated part of the tube, each larger division of which will represent 1 gr. per cent. of the pure

alkali, or its carbonate, as the case may be, in the sample under examination.

The glass tube, or *Faraday's alkalimeter*, as it is called, is here represented, and is about 9⅓ inches long, and ¾ of an inch wide; it is graduated into 100 parts, each of which represents 10 grs. of water. Opposite the numbers 23·44, 48·96, 54·63, and 65, are cut the words written in the margin, and indicate the quantity of test acid to be employed for each of these alkalis. The test acid being then poured in up to the proper marks, and the tube filled up to 1000 with pure water, gives a test solution equal to 100 grs. of the given alkalis. Consequently, the number of its divisions consumed to produce saturation, will exactly express the value per cent.



The test acid is prepared by adding pure water to pure sulphuric acid until the specific gravity is reduced to 1·127 at 60° F., (about 1 measure of acid to 4 of water.) The sp. gr. must be carefully ascertained by means of the sp. gr. bottle, and its strength checked by adding to 100 grs. of it, chloride of barium until it no longer produces a precipitate. This, when washed and dried at a low red heat, contains 33·3 per cent. of sulphuric acid, from which the strength of the test acid may be calculated. This is an *easy* method of alkalimetry, and admits of ascertaining the quantity of alkali to the ⅓ or ¼ of 1 per cent. It is best to keep a quantity of the test acid always ready prepared, as it saves trouble. Should a Faraday's alkalimeter not be at hand, any other mode by which the test liquor can be accurately measured will do as well.

II. Dissolve 100 grs. of alkali, as described in the last method, then take a known weight of the test acid prepared as directed below, and proceed to neutralize the alkaline solution therewith in the way above mentioned; then again weigh the test acid and note the quantity consumed; the loss of weight divided by 10 gives the real per centage of pure alkali.

Test acid for soda. Add pure sulphuric acid to distilled water until the sp. gr. becomes about 1·109 (about 5 water and 1 acid,) and 100 grs. of which saturate exactly 17 grs. of pure carbonate of soda dried at a dull red heat; or which is the same, 313 grs. should contain exactly 40 grs. of real sulphuric acid, when 10 grs. will be equivalent to 1 gr. of pure soda. The strength may be also tested by chloride of barium.

Test acid for potassa. This acid should be weaker than the last, its sp. gr. about 1·069 or 1·070; 471⅓ grs. should contain exactly 40 grs. of real sulphuric acid, and 1000 grs. should neutralize exactly 66⅓ grs. of dry carbonate of soda.

Remarks. The most convenient vessel to contain the test acid during the operation is Schuster's alkalimeter, described under the article ACETIMETRY. This method of alkalimetry admits of great accuracy. By careful manipulation the content of real alkali may be estimated to the one-tenth of 1 per cent. (C. Watt, jun., Chemist, No. 50.) The art of weighing admits of much greater accuracy than that of measuring, especially where small quantities are concerned. This is the method employed at Apothecary's Hall, at the Polytechnic Institution, (by Mr. L. Thompson,) in the Laboratory of Messrs. Hawes, and in various other places where great precision is desired.

III. (*Method of Fresenius and Will, of Giessen.*) *Oper.* The flask *B* (article ACIDIMETRY) is about half filled with oil of vitriol, and the sample of alkali is put into the flask *A*, and water poured on until it be almost half full. The tubes are then fitted into the apparatus quite air-tight; the end of the tube *b* is fastened with a bit of wax, and the whole is carefully weighed. The apparatus is now removed from the scales, and the mouth applied to the end of the tube *h*, and the air in the flask *B* rarefied by suction; the consequence of which is, that the oil of vitriol in *B* flows over into *A*. The evolution of carbonic acid immediately commences, which, from the construction of the apparatus, has to pass through the oil of vitriol, before it can escape by the tube *d*, by which means it is rendered quite dry. Whenever the effervescence flags, a little more acid must be sucked over, until the whole of the carbonate be decomposed, after which an additional quantity is made to pass into *A* sufficient to raise the temperature considerably, which will have the effect of expelling all the gas absorbed by the fluid during the operation. As soon as this is completed, the wax is removed from the aperture *b*, and suction applied to *h* until all the carbonic acid gas in the apparatus is replaced by atmospheric air. The whole must now be allowed to cool, when it must be again weighed. *The loss of weight* gives exactly the amount of *dry carbonic acid gas* that was contained in the specimen, from which the weight of pure alkali is estimated. Every 22·12 grs. of dry carbonic acid gas represent exactly 31·3 grs. of pure soda, and 47·15 grs. of pure potassa.

Remarks. Should the specimen contain *caustic potassa*, (as many of those of commerce do,) it should be triturated, previously to testing, with an equal weight of pure quartz sand, and about ¼ of its weight of carbonate of ammonia added; the mixture is then placed in a capsule and moistened with water, and a gentle heat applied until it be quite dry, and all the ammonia expelled. Should sulphuret of potassium or caustic soda be present in the sample, the same method must be followed, except that instead of water the powder should be moistened with liquor of ammonia; and in the case of soda, the quantity of carbonate of ammonia should be at least equal to half the weight of the test specimen. It will thus be seen that unless for *carbonates*, (unmixed with *sulphurets*, *bicar-*

bonates, or *caustic alkali*,) this method requires several operations, and is consequently very troublesome and liable to error, except in expert hands. It is, however, a ready and elegant way of testing the pure carbonates.

Concluding remarks on Alkalimetry. Rules for sampling, &c. As each sample is taken from the cask, place it at once in a *wide-mouth* bottle, cork it up immediately and number it. The sample should be drawn from as near the centre of the cask as possible. Before proceeding to the assay, throw the contents of the bottle upon a piece of clean paper, crush the lumps, and mix them with the *small;* reduce the whole to coarse powder as rapidly as possible, and weigh the number of grains for trial at *once*. In a number of casks, at least ⅛ of them should be tested. Assays of soda should never be made while warm, as it will thereby frequently indicate 1 or 2 per cent. more alkàli than when it has been cooled down and packed in casks. The method of trying the density of the test acid by merely dropping a bead of a known sp. gr. into it, as is frequently recommended by chemical reformers, is not sufficiently accurate to be depended on. Too much care cannot be taken to ensure the test acid of the proper strength, of which the sp. gr. alone is an insufficient proof. It is always best to keep a stock of the test acid (properly made and proved) ready for use.

Those desirous of entering more largely into the subject of acidimetry, alkalimetry, &c., are referred to Bullock's "Translation of Fresenius and Will;" some valuable papers by Mr. C. Watt, jun., in the fifth volume of the "Chemist;" and to a paper by Dr. Ure, in the third volume of the "Pharmaceutical Transactions."

ALKALOIDS. *Syn.* VEGETABLE ALKALIS. ORGANIC ALKALIS. ORGANIC BASES. Substances possessing basic and alkaline properties derived from the vegetable kingdom. They are compounds of carbon, hydrogen, azote, and oxygen, and have hence been distinguished by Dr. Collier, by the mnemonic word, "*chaos*," the first four letters being the initials of the elements, and the "s" showing that they are salifiable. Some of the alkaloids are the most violent poisons with which we are acquainted; one-fiftieth of a grain of pure aconitina has endangered life. (Pereira.) The greater number possess similar properties to the plant from which they are extracted, but in an eminently concentrated degree. The following table exhibits the principal alkaloids described in the body of this work, together with the plants which yield them:

Alkaloids.	*Plants.*
Aconitina	Aconitum Napellus.
Aricina	Arica Bark.
Atropia	Atropia Belladonna.
Brucia	Strychnos Nux Vomica.
Cinchonia	Cinchona Lancifolia.
Codeia	Opium.
Conia	Conia Maculatum.
Corydalia	Corydalis Tuberosa.
Cynapia	Æthusa Cynapium.
Daturia	Datura Stramonium.
Delphia	Delphinium Staphisagria.
Digitalia	Digitalis Purpurea.
Emetina	Cephaelis Ipecacuanha.
Hyoscyamia	Hyoscyamus Niger.
Meconia, Morphia, Narceia, Narcotina	Opium.
Nicotina	Nicotiana Tabacum.
Picrotoxia	Menispermum Coculus.
Quinia	Cinchona Cordifolia.
Sanguinaria	Sanguinaria Canadensis.
Solania	Solanum Nigrum.
Thebaia	Opium.
Veratria	Veratrum Sabadilla.

The following general method of procuring the alkaloids will be found applicable to such as full directions are not given for under their respective heads.

1. (*When the base is insoluble in water, non-volatile, and existing in the plant in an insoluble form.*) *Proc.* Boil or macerate the bruised plant in water acidulated with muriatic acid, filter, neutralize the acid with an alkali, (ammonia, lime, or magnesia,) and collect the precipitate, which must be purified by resolution in dilute acid, digestion with animal charcoal, and subsequent crystallization or precipitation by an alkali; or the first precipitate may be purified by dissolving it repeatedly in alcohol.

2. (*When the base is insoluble in water, and non-volatile, but existing in the plant in a soluble state.*) *Proc.* Boil or macerate in hot water as before; filter and precipitate by adding an alkali; purify as last.

3. (*When the base is soluble in water, and non-volatile.*) *Proc.* Make an infusion with a dilute acid, (muriatic;) concentrate by a gentle heat; treat the liquor with potassa and ether, (conjointly;) decant and evaporate.

4. (*When the base is both soluble in water and volatile.*) *Proc.* The vegetable or its extract may be mixed with potassa and distilled; the product, neutralized with oxalic or sulphuric acid, carefully evaporated to dryness, and digested in alcohol, and this solution agitated with potassa and ether; the ethereal solution thus formed, if carefully evaporated, leaves the base nearly pure. It may be further purified by cautious distillation.

Remarks. The above is a mere view of the four general processes of extracting the alkaloids, which, for success, require considerable address in manipulating. The plan adopted for the extraction of the principal alkaloids of commerce, will be found fully described under their respective heads.

ALKALOIDS, TESTS FOR THE. Perchloride of gold is a more decisive test of certain vegetable alkalis than the double chloride of sodium and gold, already employed for this purpose. The following are the colors of the precipitates which it produces with the salts of the annexed alkalis dissolved in water: quinine, buff-colored; cinchonine, sulphur-yellow; morphine, yellow, then bluish, and lastly, violet; in this last state the gold is reduced, and the precipitate is insoluble in water, alcohol, the caustic alkalis, and sulphuric, nitric, or hydro-chloric acids; it forms with aqua regia a solution which is precipitated by protosulphate of iron; brucine, milk-, coffee-, and

then chocolate-brown; strychnine, canary-yellow; veratrine, slightly greenish-yellow.

All these precipitates, with the exception mentioned, are very soluble in alcohol, insoluble in ether, and slightly soluble in water.

Among the reactions of chloride of gold, there are two which appear to be especially important: they are those which occur with morphine and brucine; these are sufficiently marked to prevent these alkalis from being mistaken for each other, and also yield pretty good characteristics for distinguishing brucine from strychnine. (MM. Larocque and Thibierge.)

The above authors have arrived at the following conclusions:

1st. By the aid of reagents it is possible to determine the presence of morphine, strychnine, and brucine in substances which, after being mixed with the salts of these alkalis, have undergone the vinous, acetic, or putrefactive fermentation. M. Orfila has already shown that the putrefactive fermentation does not alter morphine.

2d. Crystallized iodic acid, or a concentrated solution of this acid, is susceptible of being decomposed by neutral azotized bodies; but a dilute solution of this acid cannot be decomposed by them unless there be added concentrated sulphuric acid, crystallizable acetic acid, oxalic, citric, or tartaric acid.

3d. Iodic acid should not be employed as a test of morphine without the greatest caution.

4th. Perchloride of gold produces such effects with the vegetable alkalis, as serve to distinguish morphine, brucine, and strychnine from each other.

5th. The reagents on which the greatest reliance may be placed as tests of morphine are, nitric acid, neutral perchloride of iron, and perchloride of gold.

6th. By the use of reagents, morphine which has been mixed with beer, soup, or milk, may be detected.

7th. It is also easy to prove by reagents the presence of meconic acid in soup or milk, especially when the meconate of lead is decomposed by dilute sulphuric acid. (Phil. Mag., Dec., 1842.)

ALKANET. *Syn.* Alkanet Root. *Qual., use, &c.* The best alkanet is brought from the neighborhood of Montpellier. The bark contains a beautiful red color, which it freely gives to oils, fats, wax, spirits, essences, and similar substances, by simple infusion, and is consequently much employed to color varnishes, ointment, pomatums, &c. Wax, tinged with alkanet and applied on warm marble, stains it of a beautiful flesh-color, which sinks deep into the stone, and is possessed of considerable permanence. The spirituous tincture of alkanet gives a deep red to marble.

In selecting this article, the smaller roots should be chosen, as they possess more bark than the larger ones in proportion to their weight.

ALKERMES. A cordial liqueur much esteemed in some parts of the south of Europe.

Prep. I. *Ing.* Bay leaves 1 lb., mace 1 lb., nutmegs and cinnamon, each 2 oz.; cloves 1 oz., all bruised; cognac brandy 3½ gallons. *Proc.* Macerate for 3 weeks, frequently shaking, then distil over 3 gallons, and add clarified sirup of kermes 18 lbs., orange flower water 1 pint; mix well and bottle. *Remarks.* The above is the true formula for the alkermes de Santa Maria Novella, which is much valued.

II. Spice as last, 4 gallons of British brandy, water 1 gallon; macerate as before, and draw over 4 gallons, to which add 2 gallons of capillaire, and 4 oz. of sweet spirits of nitre. (Cassia may be used for cinnamon.)

ALLANTOIN. *Syn.* Allantoine. Allantoic Acid. *Hist.* Discovered by Vauquelin and Buniva in the allantoic fluid of the cow. It has since been produced artificially by Wohler and Liebig.

Prep. I. Evaporate the allantoic fluid of the cow to ¼ or ⅕ of its volume, when, on cooling and standing for some time, crystals will be deposited These must be purified by resolution, digestion with animal charcoal, and recrystallization.

II. Boil 1 part of uric acid in 20 parts of water, then add thereto, gradually, freshly-precipitated and well-washed oxide of lead until the color ceases to change. Filter while hot, evaporate until a pellicle forms on the surface, and set it aside to crystallize. Purify as above.

Prop. Small prismatic crystals, scarcely soluble in water; nitric acid converts it into allanturic acid.

ALLANTURIC ACID. A new nitrogeneous acid, discovered by Pelouze, produced by the action of nitric acid on allantoin. The name is derived from allantoin and uric acid, the new compound being made from the former, and being analogous in composition to the latter.

Prep. Dissolve allantoin in nitric acid (1·2 to 1·4) with a gentle heat; on cooling, pour the liquor from the crystals of nitrate of urea which are deposited, evaporate, and dry at 80° F. Treat the residuum with weak water of ammonia, and add alcohol; collect the white viscid matter thrown down, redissolve it in water, and again precipitate it with alcohol; the last precipitate is the acid.

Prop. Little is known about it.

ALLIGATION. An arithmetical rule for finding the price of mixtures, and for making mixtures of any given price or value. From its great use in trade, and ease of performance, it should be understood by every tradesman. (Vide Joyce or Walkingame.) Questions in alligation may also be very easily determined by the method of indeterminate analysis, by persons but slightly conversant with elementary algebra. This rule has been applied to ascertain the proportions of compounds from their sp. gr. when they have undergone no change in volume; but when this is the case, as in alloys, alcoholic mixtures, &c., it is quite inapplicable.

ALLOXAN. *Syn.* Erythric Acid. A product of the decomposition of uric acid by nitric acid, first noticed by Brugnatelli, and afterwards by Wohler and Liebig.

Prep. Gradually add uric acid to nitric acid (sp. gr. 1·35) gently heated, until crystals begin to appear; then cool, and throw the mass on a funnel choked with asbestos to drain, and afterwards drop on it a little cold water, to displace the last adhering portions of acid liquor; when well drained dissolve in water, and crystallize, employing but little heat. The acid liquor will yield 4 or 5 crops of crystals by treating it as often with fresh uric acid. *Prod.* 80 to 90% of the uric acid employed.

Prop. Crystals efflorescent; treated with alkalis it yields alloxanic acid.

ALLOXANIC ACID. An acid discovered by Wohler and Liebig; it is formed when alloxan is decomposed by the alkalis. *Prep.* Treat an aqueous solution of alloxan with baryta water, and decompose the alloxanate of Barytes formed with dilute sulphuric acid; decant, evaporate, and crystallize. *Prop.* With the bases it forms salts called *alloxanates;* these may generally be made from the alloxanate of baryta or ammonia by double decomposition; some of them are soluble.

ALLOXANTINE. Obtained by Prout from uric acid.

Prep. I. Boil 1 part of uric acid in 32 parts of water, and add dilute nitric acid until it be dissolved; evaporate to ⅔ds, and set it aside for 12 hours; the crystals, which will then be found deposited, must be purified by resolution and crystallization.

II. Dissolve alloxan in water, and pass sulphuretted hydrogen gas through the solution, until the alloxantine be deposited as a crystalline mass, which must be purified by resolution and crystallization.

ALLOY. *Syn.* Allay. Alliage, (*Fr.*) Legirung, (*Ger.*) (From the French verb *Alloyer*, to mix one metal with another for the purposes of coinage.) Combinations of the metals with each other obtained by fusion. The term was formerly restricted to gold and silver when mixed with metals of inferior value, but is now applied to any mixture of two or more metals.

Prop. Most of the metals unite with each other by fusion or amalgamation, and acquire new properties. Thus: *copper,* alloyed with *zinc,* becomes *brass,* and possesses a different density, hardness, and color to either of its constituents. It is yet undecided whether alloys tend to be formed in definite or equivalent proportions of the metals of which they are composed, or unite in any ratio, like sugar and water. The proportions contained in the natural alloys of gold and silver, as well as some phenomena attending the cooling of several alloys, from a state of fusion, go far to show the former to be the case. (Rudberg.) As, however, the metallic compounds are generally soluble in each other, or combine by fusion and mixture, their nature is much obscured. Alloys generally melt at lower temperatures than those required for the fusion of their separate metals, which affords strong evidence of a chemical change having taken place. They also usually possess more tenacity and hardness than the mean of their constituents; but their malleability, ductility, and their power of resisting oxygen are diminished. The combination of two brittle metals is always *brittle;* that of a brittle and a ductile metal *generally so;* and this is also sometimes the case with two *ductile* metals. From the number of the metals, it is evident that several hundred combinations may be made, but about 60 are all that have been carefully examined by the chemist, and not more than ⅓d part of that number has been applied to useful purposes. Among these, however, may be found some possessing most valuable properties, not to be met with in the pure metals.

Prep. No general rules for the manufacture of alloys applicable to each can be given; but it may be remarked that, in uniting those metals, differing greatly in their fusibility, the more fusible one should not be added to the other until it be melted, or sufficiently heated, and then at the lowest possible temperature at which a perfect union will take place between the two, lest the more fusible one should evaporate or be oxidized, and thus cause the compound to be imperfect. The mixture is usually effected under a flux, or some material that will prevent evaporation and exposure to the atmosphere. Thus: in melting lead and tin together, in forming solder, resin or tallow is thrown upon the surface; in tinning copper, the surface is rubbed with sal ammonia; and in combining some metals, powdered charcoal is used for the same purpose. For further information on this subject, the reader is referred to the following table, and to the separate articles devoted to the more important alloys. (See Bronze, Brass, Pewter, &c.)

Table of the principal Alloys.

Combining metals.	*Alloys produced.*
Arsenic and copper . . .	White Copper or Packfong.
Tin and Lead	Solder and Common Pewter
Tin with Antimony, Copper, and Bismuth	Best Pewter or Britannia Metal.
Tin with Lead and Bismuth	Fusible Metal.
Tin and Copper	Bronze Metal, Speculum do. Bell do. Cannon do.
Copper and zinc	Brass. Dutch gold.
Copper with Zinc, Nickel, and Iron	German silver.
Silver and Copper . . .	Standard Silver.
Gold with Copper and Silver	Do. Gold.
Mercury and other Metals	Amalgams.

(See also Amalgams.)

ALMOND TREE, (Amygdalus communis.) The kernels, *sweet almonds*, are pectoral and cooling, but mawkish; imported from the south of Europe and the Barbary coast. *Blanched almonds.* Almonds thrown into boiling water until the skin comes off by pressing between the fingers, the hot water is then strained away, the almonds flung into cold water, peeled, and dried, either in a stove or the sun, until they are brittle. *Burnt almonds.* Used to color and flavor liqueurs. *Bitter almonds.* A variety, imported from Mogadore, used to relieve the flavor of the sweet almonds, and to clear muddy water; both pressed for oil. *Almond cake,* left on pressing the oil, used for washing the hands.

Remarks. Almonds are principally used for obtaining the oil; and in medicine for the preparation of a confection and mixture; and in confectionary, as an agreeable flavoring, &c.

ALMOND FLAVOR. *Syn.* Essence of bitter Almonds. Essence of peach Kernels. Quintessence of Noyeau, &c. *Prep.* Dissolve 1 oz. of essential oil of bitter almonds in 1 pint of spirits of wine.

Prop., uses, &c. Used as a flavoring for wine, cordials, perfumery, pastry, &c., and in any case where it is wished to impart an agreeable nutty flavor or smell; also to prepare bitter almond water. *Caution.* It should be used in very small quantities, as it is very powerful. *A few drops are sufficient for several pounds of pastry.*

ALMONDS, TO CANDY. *Oper.* Blanch

any quantity of almonds, then fry or bake them in butter, until they acquire a light brown color; wipe them with a napkin, pour over them sirup, (boiled to a thread,) and stir until cold.

Remarks. According to Mrs. Rundel, almonds so prepared were highly thought of by the London guests of his Highness Prince Ekbaladoola, the Nawaub of Oude, from whose cook this receipt was obtained.

ALMOND PASTE. *Prep.* Blanched almonds 4 oz.; white of 1 egg; spirit of wine and rose water, q. s. *Proc.* Beat the almonds to a smooth paste in a mortar, then add the white of egg and enough rose-water, mixed with ½ its weight of spirit of wine, to give the proper consistence. *Use.* As a cosmetic, to prevent chapped hands, &c.

Remark. The skins will easily come off if the almonds be immersed for a few minutes in boiling hot water.

ALOES. As there are several descriptions of this drug, and the commoner sorts are frequently sold for the more expensive, the following characteristics will assist the reader in recognising such deceptions.

ALOES, SOCOTRINE. *Char.* Color, garnet red to golden red; smell, peculiar and aromatic, not unlike a decaying russet apple, especially when breathed on or warmed; taste, permanently and intensely bitter; fracture, conchoidal; softens in the hand and becomes adhesive, yet retains considerable brittleness; powder, *bright golden yellow color;* central portions of the lumps often soft, especially when first imported. The Ed. Ph. states that socotrine aloes should be "in thin pieces, translucent and garnet red, almost entirely soluble in spirit of the strength of sherry; very rare."

ALOES, HEPATIC. *Char.* Less odorous, darker-colored, and more opaque than the preceding; digested in spirit of wine, gives a yellow granular powder, resembling lycopodium, and insoluble in water, alcohol, ether, and dilute sulphuric acid; but freely soluble in liquor of potassa, which it turns red. *Remarks.* The finer and paler samples of this aloes constitute the mass of what is sold for socotrine. It yields a powder of a duller color than the latter.

ALOES, BARBADOES. *Char.* Color, dark brown or black; smell, strong and unpleasant, especially when breathed upon; powder, *dull olive yellow.*

ALOES, CAPE. *Char.* Smell, stronger than the last; color, deep greenish brown; appearance, shining and resinous; fracture, glassy; powder, lively *greenish-yellow color.*

Remarks. The above are the principal kinds of aloes; but there are several other common sorts, as the Mocha, Caballine, and Indian, all of which are melted and doctored up by the conscientious druggist, and sold for Barbadoes and hepatics. They may, however, be readily distinguished by an experienced person, by their odor and appearance, which are widely different.

ALOES, STRAINED. *Syn.* MELTED ALOES. ALOE COLATA. *Oper.* I. Melt aloes in a copper pan by the heat of a steam or water-bath, then press them through a strong hair or wire sieve.

II. Melt the aloes as above, but with the addition of about twice their weight of water, strain and evaporate.

Remarks. Mocha and other common aloes, treated in this way and colored, are frequently sold for *melted* socotrine and hepatics. The coloring employed is usually the precipitated carbonate of iron (sesquioxide) or Venetian red, in fine powder, and sometimes a little annatto. The imposture is not readily detected by mere inspection by any one unaccustomed to these matters, hence the impunity with which the fraud is perpetrated. The object in melting aloes is to deprive it of the foreign matters, which it generally contains in large quantities, as sand, leaves, pieces of wood, &c. The action of the heat drives off much of the nauseous smell from the commoner kinds, at the same time that it deepens their color and renders their appearance more translucent and resinous, and hence disguises their original nature. The operation of melting aloes on the large scale, is usually carried on at *night,* in consequence of the nauseous fumes evolved, which may be smelt at a great distance.

ALOETIC ACID. This acid exists in a watery solution of aloes. Trommsdorf supposed it to be the gallic acid, but Dr. Pereira regards it as a distinct principle. Gallic acid gives a blue color with the persalts of iron, but infusion of aloes produces an olive brown one. (Pereira.) *Prep.* It is prepared by adding diacetate of lead to an infusion of aloes, and decomposing the precipitate with sulphureted hydrogen. *Remarks.* This acid must be distinguished from polychromic, chrysammic, and other acids produced from aloes by the action of nitric acid.

ALTERATIVES. (From the Latin *altero,* I change.) Medicines that establish the healthy functions of the body, without producing any sensible evacuation, by perspiration, vomiting, or purging. Small doses of the preparations of mercury are among the most useful and generally employed alteratives. Various formulæ for alterative medicines will be found in this work.

ALTHIONIC ACID. Discovered by Regnault in the residual liquor from the preparation of olefiant gas, from alcohol, and oil of vitriol.

Prep. Dilute with water and neutralize with hydrate or milk of lime. Decant the solution, which contains althionate of lime, evaporate and crystallize. Dissolve the crystals in water, and precipitate with oxalic acid; the solution is dilute althionic acid.

Prop. A sour liquid, forming salts, called althionates, with the bases, which have the same composition as the sulpho-vinates; they are, however, distinct salts. (Regnault and Ettling.)

ALUM. *Syn.* LUMP ALUM. ROCK ALUM. SULPHATE OF ALUMINA AND POTASH. ALUMEN, (*Lat.;*) ALUN, (*Fr.;*) ALAUN, (*Ger.;*) ALUIN, (*Dut.*) A salt composed of alumina, potassa, and sulphuric acid, and in its usual state, a large quantity of combined water.

Manufact. The principal alum works in England are near Paisley and Whitby. The minerals from which it is procured are called aluminous slate, shale, or schist, and frequently alum ore. *Proc.* The ore, placed in heaps and moistened from time to time with water, becomes gradually hot, and falls into a pulverent state. When it does not possess this property, by mere exposure to air and moisture, it is broken into pieces and laid

upon a bed of brushwood and small coal, to the depth of about 4 feet, when the pile is fired, and fresh lumps of alum rock thrown on, until the mass becomes of considerable height and size; the combustion is then conducted with a smothered fire, until the calcination is complete. The pile is then allowed to cool, and further exposed to the action of air and moisture. The residuum of the burning is now placed in large stone cisterns, and thoroughly edulcorated with water, until all the soluble portion is dissolved; the solution is then concentrated in another stone cistern, so made that the flame and heated air of its reverberatory furnace sweep the surface of the liquor. The evaporation is continued until it is *near* the point, but *somewhat weaker* than that at which it would deposite crystals on cooling; it is then run off, after defecation, into other cisterns, and solution of common muriate or sulphate of potassa, or (sometimes) impure sulphate or carbonate of ammonia, is added until a cloud or milkiness ceases to be produced on adding more; it is then allowed to settle and get thoroughly cold, and the supernatant mother liquor being drawn off with a pump or syphon, the precipitate is well drained. It is next well washed by stirring it up with a little *very cold water*, which after draining off, the operation is repeated a second time. A saturated solution of the alum is then formed in a leaden boiler, and the clear portion is run off, while boiling hot, into crystallizing vessels, called "*roaching casks*," from which it is taken, after the lapse of about a week, in the form of large crystalline masses, which are broken up and packed in casks for sale.

Remarks. The above is an outline of the most approved mode of making the alum of commerce. It has lately, however, been made at some chemical works on the banks of the Tyne, by the direct combination of oil of vitriol with a pure aluminous clay, the potash being afterwards added. This is a revival of the method first adopted by Chaptal. A *patent alum* is manufactured at the same works, which contains *no alkali*, and is, consequently, preferable for dyeing, as it is the alumina alone that forms the valuable ingredient in alums. Salts having the same general appearance and behavior as common alum, may be made by replacing the sulphate of potassa in the common alum, by ammonia or soda. Such compounds are known as ammonia and soda alum. The best sort of alum is formed when potassa alone has been employed in its manufacture. Good alum contains about 11 per cent. of alumina, 10 per cent. of potassa, 33 of sulphuric acid, and 46 of water.

Uses, &c. Alum is used in large quantities in many manufactories; added to tallow, it renders it harder; printers' cushions, and the blocks used in the calico manufactory, are rubbed with burnt alum to remove any greasiness, which might prevent the ink or color from sticking. Wood, sufficiently soaked in a solution of alum, does not easily take fire; and the same is true of paper impregnated with it, which is fitter to keep gunpowder, as it also excludes moisture. Paper impregnated with alum is useful in whitening silver, and silvering brass without heat. Alum mixed in milk helps the separation of its butter. If added in a very small quantity to turbid water, in a few minutes it renders it perfectly limpid, without any bad taste or quality; while the sulphuric acid imparts to it a very sensible acidity, and does not precipitate so soon, or so well, the opaque earthy mixtures that render it turbid, as I have often tried. It is used in making pyrophorus, in tanning, and many other manufactures, particularly in the art of dyeing, in which it is of the greatest and most important use, by cleansing and opening the pores on the surface of the substance to be dyed, rendering it fit for receiving the coloring particles, (by imparting alumina to the stuff,) and in this way making the color fixed. Crayons generally consist of the earth of alum, finely powdered, and tinged for the purpose. *In medicine* alum is used as a tonic and stringent, in doses of 5 to 20 grs.; as a gargle, (ʒj to ½ pint of water;) and as a collyrium and injection, (10 to 15 grs. to 6 oz. of water.) In lead colic, ʒss to ʒij of alum dissolved in gum water, every 3 or 4 hours, is said to be infallible. Powdered alum is frequently applied with the tips of the fingers, in cases of sore throat and ulcerations of the mouth, &c.

Pur. The usual impurity which renders alum unfit for the uses of the dyer, is the ferro-sulphate of potassa, but if iron be present in any other shape, it is equally injurious. Common alum frequently contains ammonia, from urine or the crude sulphate of the gas-works, having been employed in its manufacture. This may be detected by adding a little quicklime or caustic potassa. Powdered alum is commonly adulterated with large quantities of common salt, when its solution may be tested as described for muriatic acid and the muriates. Pure alum should form a colorless solution with water, and give a white precipitate with pure potassa soluble in an excess of the latter. It should suffer no change on the addition of tinct. of galls, prussiate of potash, or sulphureted hydrogen.

Ant. When excessive doses of alum have been taken, an emetic of sulphate of zinc should be given immediately, followed by copious draughts of warm water, and as soon as the vomiting ceases, give a purgative.

ALUM, BURNT. *Syn.* Dried Alum. Alumen ustum. Alumen siccatum. A. exsiccatum. *Proc.* Liquefy alum in a shallow earthen vessel over the fire, then cautiously raise the heat until ebullition has ceased. (P. L.)

Remarks. It is better to take *more time*, than to employ *too much* heat, lest a portion of the acid be driven off as well as the water. *Use.* Similar to common alum, but less soluble; dose 10 to 20 grs. in colic; it is used as an escharotic to burn down proud flesh, &c.

ALUM, IRON. *Prep.* Mix the solution of sulphate of potassa with a solution of tersulphate of peroxide of iron, and crystallize by spontaneous evaporation.

Remarks. This salt for the most part resembles common alum. It has *sometimes* a slight pink color. In a similar way may be made chrome and manganese alums. In all these salts ammonia may be substituted for potassa, with similar results.

ALUM, ROACH. *Syn.* Roman Alum. Turkey Alum. Red Alum, &c. A very pure sort of alum, imported from Roccha in Syria, and Tolfa in Italy, covered with an efflorescence of a palish

red or rose color. The article generally met with in commerce under this name is, however, nothing but common English alum, broken into pieces about the size of almonds, and colored with a little bole or rose pink. This is done by shaking the fragments in a sieve over a vessel of hot water, and then stirring them up with the color, until the surface is uniformly tinged therewith. In the genuine roach alum, the color not only covers the surface, but also partially pervades the substance of the crystals.

ALUM, WHEY. *Prep.* Boil ½ oz. of alum with a pint of milk, and strain it. *Use.* A wine-glassful in diarrhœa two or three times daily.

ALUMINA. *Syn.* Pure Alumine. Oxide of Aluminum. Magistery of Alum. Aluminous Earth. Earth of Alum. Argil, &c. This substance is the base of the common alum, just described, and is about one of the most abundant productions of nature. It forms a large proportion of the clay out of which bricks, pipes, and earthenware are manufactured, and in a pure and crystallized state, constitutes the ruby and sapphire, two of the hardest and most valuable of the gems.

Prep. I. Dissolve alum in 6 times its weight of boiling water, add a solution of carbonate of potassa, (in slight excess,) agitate for a few minutes, filter and wash with distilled water. To render this *perfectly* pure, it must be dissolved in weak muriatic acid, and again thrown down with ammonia, washed with water, and exposed to a white heat in a crucible. (Berzelius.)

II. Precipitate a solution of alum with a solution of chloride of barium, filter, evaporate to dryness, and ignite the residuum. (Liebig.)

III. Expose perfectly pure ammonia alum to a white heat. (Gay Lussac.)

Remarks. It is necessary to employ perfectly pure alum to prevent the product being vitiated. The third is the simplest process, where pure ammonia alum can be got; but as this is seldom the case, the second should be used in preference to the first. The hydrate of alumina, in the moist state, is used to mix with oxide of cobalt, and several other substances, as a base for the color. In this form it is sometimes called gelatinous alumina.

ALUMINA AND ITS SALTS, TESTS FOR. 1. Ammonia and the alkaline carbonates separate a bulky white powder (hydrate of alumina) from its solutions in the acids. 2. Pure potassa and soda throw down a white powder, soluble in excess of the precipitant. 3. Phosphate of ammonia gives a white precipitate. 4. Iodide of potassium causes a white precipitate, passing into a permanent yellow. 5. At a strong red heat its salts part with some of their acid. 6. Neither oxalate of ammonia, tartaric acid, prussiate of potash, nor tincture of galls, disturb their solutions. 7. Bisulphate of potash, added to concentrated solutions, gives a precipitate of octohedral crystals of alum. (See the article Bread.)

ALUMINA, ACETATE OF. *Prep.* I. Add a solution of acetate of baryta to another of sulphate of alumina.

II. (*Calico printer's mordant.*) *Prep.* Add 100 parts of alum to 120 parts of sugar of lead, each being first dissolved separately in hot water, and allowed to cool before mixing; decant the clear liquor.

Prop. Very soluble in water; astringent; by evaporation, it may be procured as a gummy mass but much heat decomposes it. *Use.* In calico printing as a mordant, mixed with starch or gum to thicken it. In dyeing, as a mordant, the thickening being omitted. Its valuable properties depend upon the feeble affinity existing between its constituents, which is counterbalanced by that of the cotton fibres at a moderate heat. Chemically pure acetate of alumina is made by the first formula, or by dissolving the fresh hydrate in concentrated acetic acid. The dyer's mordant, made like No. II., contains much sulphate of potassa, which is necessary for its proper action on the cloth.

ALUMINA, SULPHATE OF. *Syn.* Tersulphate of Alumina. *Prep.* Saturate dilute sulphuric acid with the freshly precipitated hydrate, evaporate, and crystallize.

Remarks. Crystallizes with difficulty. The disulphate falls down from its solution when ammonia is added. The mineral called aluminite, found near Newhaven, in Sussex, and other places, is a disulphate of alumina.

ALUMINUM. *Syn.* Aluminium. The metallic base of alumina; discovered by Davy. The following is Wohler's method of obtaining this metal.

Prep. Make a thick paste of alumina, powdered charcoal, sugar, and oil, and heat it in a covered crucible until all the organic matter is destroyed; then transfer the product to a porcelain tube, and connect the one end with another tube containing dried muriate of lime, and the other end with a small tubulated receiver. Then expose the porcelain tube to the heat of a small oblong furnace, and having connected the muriate of lime tube with a vessel disengaging chlorine, pass the gas through the apparatus, at the same time raising the heat of the tube to redness. In one or two hours, or as soon as the tube becomes choked, the whole must be allowed to cool, and taken to pieces, and the chloride of aluminum thus formed collected. 9 or 10 pieces of potassium, of about the size of peas, are then to be placed in a platina crucible, and upon them an equal number of similar pieces of the sesquichloride of alumina, formed as above; the cover is now to be put on and secured in its place with a wire, and the heat of a spirit lamp cautiously applied, until the spontaneous incandescence of the matter ceases. When cold, throw the crucible into a large vessel of cold water, agitate and collect the gray powder deposited, and again wash it well and dry it.

Prop. A gray powder, consisting of small metallic scales, resembling platina. It is not acted on by cold water, but is dissolved by the alkalis and some of the acids. Heated to redness, it catches fire and burns with great rapidity in the air, and in oxygen gas, with intense brilliancy. The powder, blown upon the flame of a candle, displays an immense number of inflamed points of great splendor. When heated to redness in the vapor of phosphorus, it burns vividly, and produces *sesquiphosphoret of aluminum.* When mixed with selenium and exposed to heat, a blackish powder, or *seleniuret of alumina,* is formed. When heated until strongly incandescent, and small pieces of sulphur dropped upon its surface, the most brilliant

combustion ensues with the formation of the *sesquisulphuret*. Both this and the last article possess a semi-metallic lustre, and are easily decomposed by exposure and moisture. Should any of the chloride remain unconsumed, it may be preserved in naphtha.

AMADOU. This word is derived from the French, and is applied to a spongy, combustible substance, made from a species of mushroom, (the boletus igniarius,) which grows on the trunks of some old trees.

Collect. and prep. It should be collected in the months of August and September, and the outer bark having been removed with a knife, the inner spongy light-brown substance must be carefully separated from the woody part below. It must be next cut into slices and well beaten with a hammer or mallet, until they become soft and easily pulled to pieces between the fingers. It is now fit for use.

Uses, &c. It is used for stopping bleeding and some other surgical purposes. When covered with resin plaster, it forms an excellent article for the protection of abraded surfaces in exposed situations, and a small piece thus prepared, of a circular shape, having a round hole cut in the middle, the size of the apex of the corn, forms the very best corn-plaster, as from its great softness it at once protects the part from pressure, and removes the cause. It is also used to make a match or tinder.

AMADOU TINDER. *Syn.* Boletus Tinder. German Tinder. Spunk. Touchmatch. Touchwood. *Prep.* I. Boil the prepared amadou in a strong solution of saltpetre, dry and beat it well with a mallet, then again soak it in the solution, dry and rub out the excess of saltpetre.

II. Make a thin paste with gunpowder and water, to which a little spirit may be added, then thoroughly imbue the prepared amadou with it; dry, beat out the loose powder, and again rub it with the paste; lastly, dry and rub out the loose matter.

Remarks. From the color of the last tinder, it has received the name of black spunk; the former is the most cleanly, the last the most combustible. The former is sometimes called red amadou. It is much used as a touchmatch, and instead of tinder, especially on the continent, where most smokers, prior to the general use of congreves, carried a box with them containing a little amadou and a small flint and steel.

AMALGAMS. (From ἅμα, together, and γαμεῖν, to marry.) Substances formed by mixing quicksilver with another metal. Alloys containing quicksilver. *Remarks.* Mercury unites with most of the metals by mere contact, forming amalgams. These are employed for various purposes in the arts, as silvering, gilding, coating mirrors, &c. (See the following Articles.)

AMALGAM, AMMONIACAL. This is a compound of mercury, hydrogen, and nitrogen, produced by placing a globule of metallic mercury in a small cavity, formed in a piece of sal ammoniac; the negative pole of a powerful voltaic battery is then brought in contact with the metal, and the positive pole with the ammoniacal salt. After a few seconds an amalgam of a ramified shape, and of the consistence of soft butter, is formed. On withdrawing the influence of the battery, the whole returns to its former condition. 2. By putting an amalgam of mercury and potassium into the moistened cavity of the sal ammoniac, similar results ensue. *Remarks.* The phenomena attending the formation of this amalgam have been brought forward to prove the compound nature of nitrogen and the existence of the theoretical base ammonium.

AMALGAM, ELECTRICAL. *Ing.* Zinc and tin, 1 oz. each; quicksilver, 2 oz. *Proc.* Melt the first two in an iron ladle, then withdraw it from the fire and add the mercury also, made hot; stir well together with an iron rod, pour the melted metal into a wooden box, and shake it violently until cold. It should be preserved in a corked glass vial.

Use For covering the cushions of electrical machines, for which purpose, a little must be poured out on a piece of clean paper, crushed quite smooth with a flat knife, and then spread thinly on the surface of the rubber, previously touched over with a little tallow.

AMALGAM OF GOLD. *Prep.* Place one part of gold in a small iron saucepan or ladle, perfectly clean, then add 8 parts of mercury, and apply a gentle heat, when the gold will dissolve; agitate the mixture for one minute, and pour it out on a clean plate or stone slab.

Use. For gilding brass, copper, &c. The metal to be gilded is first rubbed over with a solution of nitrate of mercury, and then covered with a very thin film of the amalgam. On heat being applied, the mercury volatilizes, leaving the gold behind.

Remarks. A much less proportion of gold is often employed than the above, where a very thin and cheap gilding is required, as by increasing the quantity of the mercury, the precious metal may be extended over a much larger surface. A similar amalgam prepared with silver is used for silvering.

AMALGAM FOR MIRRORS, &c. *Ing.* Lead and tin of each 2 oz.; bismuth 2 oz.; mercury 4 oz. *Proc.* Add the mercury to the rest in a melted state and removed from the fire; mix well with an iron rod.

Uses, &c. This amalgam melts at a low heat, and is employed for silvering the insides of hollow glass vessels, globes, convex mirrors, &c. The glass being well cleaned, is carefully warmed, and the amalgam, rendered fluid by heat, is then poured in, and the vessel turned round and round, so that the metal may be brought in contact with every part of the glass, which it is desired to cover. At a certain temperature this amalgam readily adheres to glass.

AMBER. *Syn.* Succinum (*Lat.*); Succin (*Fr.*); Bernstein (*Ger.*) A yellow semi-transparent, vegeto-mineral substance, somewhat resembling copal, much used for the manufacture of trinkets, mouth-pieces for pipes, &c. It is found upon the coasts of the Baltic Sea, Sicily, Poland, Saxony, Siberia, Greenland, &c.

Remarks. The finer sorts of amber fetch very high prices. A piece of a pound weight is said to be worth from 10*l.* to 15*l.* 5000 dollars were lately offered in Prussia for a piece weighing 13 lbs., and which, it was stated by the Armenian merchants, would fetch from 30 to 40,000 dollars in Constantinople. It would thus appear to be more valued

in the east than in England. In the royal cabinet, Berlin, there is a piece weighing 18 lbs., and supposed to be the largest ever found. The coarser kinds are employed in medicine, chemistry, and the arts.

Identity. Amber may be known from mellite and copal, both of which articles are occasionally substituted for it, by the following characteristics. 1. *Mellite* is infusible by heat, and burns white. 2. A bit of copal, heated on the point of a knife, catches fire, and runs into drops, which flatten as they fall. 3. Amber burns with spitting and frothing, and when its liquefied particles drop, they rebound from the plane on which they fall. (M. Haüy.)

AMBER IS JOINED AND MENDED by smearing the surfaces of the pieces with linseed or boiled oil, and then strongly pressing them together, at the same time holding them over a charcoal fire, or heating them in any other way in which they will not be exposed to injury.

AMBER IS WORKED in a lathe, polished with whiting and water or oil, and finished off by friction with flannel. During the operation the pieces often become hot and electrical, and fly into fragments, to avoid which, they should be kept cool, and only worked for a short period at a time. The workmen are said to suffer considerably from electrical excitement, often experiencing severe nervous tremors of the hands and arms.

AMBER, FACTITIOUS. *Prep.* Dissolve shellac in an alkaline lye, then pass chlorine through the solution until the whole of the lac is precipitated. After washing in water, this must be melted and kept over the fire until it runs *clear*, taking care that it does not burn; it should then be poured into moulds of the size of the pieces required.

Remarks. The darkest and hardest pieces of copal are also often substituted for amber. The above operation requires considerable management. (See CHLORINE and GAS.)

AMBER, SOLUBLE. *Prep.* Heat the amber cautiously in an iron pot, over a clear fire, until it softens and becomes semi-liquid; then add pale boiled linseed oil, heated very hot, and well mix it in by stirring. The best proportions are 3 lbs. of oil to 4 lbs. of amber.

Uses, &c. In this state, on being cooled a little, it may be made into a varnish by the addition of oil of turpentine; or it may be preserved for any length of time if covered from the air, and is always ready for the above purpose on being gently heated. It is sometimes used as a cement for glass and earthenware, by rubbing it on the edges of the broken piece, previously heated. Amber is soluble in sulphuric acid and the pure alkalis, but neither of these solutions can be used in the arts. The previous method is that followed by the varnish-makers.

AMBER, TO IMPROVE. There are two methods practised by the workman to harden common amber, and to render it clearer. *Oper.* I. Boil the pieces of amber in rape oil for 24 hours. II. Surround the amber with clean sand in an iron pot, and expose it to a gradually increasing heat for 30 or 40 hours. During this process pieces must be kept in the sand at the side of the pot, for the purpose of occasional examination, lest the heat be raised too high, or be too long continued. *Remarks.* The second process is said to require much skill and experience for its successful performance.

AMBER, CAMPHOR. *Syn.* CRYSTALLINE PYRETINE. VOLATILE RESIN OF AMBER. This substance is obtained as a yellowish light sublimate towards the end of the process of the destructive distillation of amber in close vessels; it comes over after the last portion of the oil, and is found in the neck of the retort.

AMBER VARNISH. *Prep.* Amber 1 lb.; pale boiled oil 10 oz.; turpentine 1 pint. *Proc.* Render the amber, placed in an iron pot, semi-liquid by heat; then add the oil, mix, remove it from the fire, and when cooled a little, stir in the turpentine.

II. To the amber, melted as above, add 2 oz of shellac, and proceed as before.

Remarks. This varnish is rather dark, but remarkably tough. The first form is the best. It is used for the same purposes as copal varnish, and forms an excellent article for covering wood, or any other substance not of a white or very pale color. It dries well, and is very hard and durable.

AMBER VARNISH, BLACK. *Prep.* Amber 1 lb.; boiled oil ½ pint; powdered asphaltum 6 oz.; oil of turpentine 1 pint. *Proc.* Melt the amber, as before described, then add the asphaltum, previously mixed with the cold oil, and afterwards heated very hot, mix well, remove the vessel from the fire, and when cooled a little add the turpentine, also made warm.

Remarks. Each of the above varnishes should be reduced to a proper consistence with more turpentine if it be required. The last form produces the *beautiful black varnish* used by the coach-makers. Some manufacturers omit the whole or part of the asphaltum, and use the same quantity of clear black rosin instead, in which case the color is brought up by lampblack reduced to an impalpable powder, or previously ground very fine with a little boiled oil. The varnish made in this way, lacks, however, that richness, brilliancy, and depth of blackness imparted by asphaltum.

AMBERGRIS. *Syn.* AMBERGRISEA (*Lat.*) AMBREGRIS (*Fr.*) A substance found in irregular masses floating on the sea in tropical climates, and supposed to be a morbid secretion of the liver or intestines of the spermaceti whale. *Prop.* Dirty pale color; very odorous; lighter than water; largely employed in perfumery. *Pur.* From its high price (about 21s. per oz. retail) it is frequently adulterated with cheaper matter. When quite pure it is nearly or wholly soluble in hot ether and alcohol, and yields about 85% of ambreine. Its sp. gr. should not exceed ·926 nor be less than ·780. It should adhere to the edge of a knife when scraped, and should yield to the pressure of the nails. It melts at 144°, and flies off as a white vapor at 212°. It should burn with an agreeable odor, and leave no notable quantity of ashes. It is frequently adulterated with gum benzoin, labdanum, farina, meal, &c., mixed together, and scented with musk. *Dose, &c.* It has been given in doses of 3 to 10 grs. as an aphrodisiac.

AMBERGRIS, FACTITIOUS OR REDUCED. An article is sold of this description, which is made in the following way. *Prep.* Ben nuts 6 oz.; spermaceti 8 oz.; gum benzoin 20 oz.; or-

ris powder 16 oz.; starch 8 oz.; asphaltum 3 oz.; mucilage of gum tragacanth q. s.; good grain musk 1 oz.; genuine ambergris 8 oz.; liquor of ammonia 1 oz. *Proc.* Beat to a perfectly homogeneous mass, make it up into lumps, and dry.

Remarks. This article is readily distinguished from genuine ambergris by its imperfect solubility in alcohol.

AMBREINE. *Syn.* AMBREINA. ODOROUS PRINCIPLE OF AMBERGRIS. *Prep.* Digest ambergris in hot alcohol of 0·827 until the latter will dissolve no more, then filter. The ambreine will be deposited on cooling, in an irregular crystalline mass. It may be purified by resolution.

Prop. White, smells of amber, and is often advantageously substituted for that substance in perfumery. Melts at 86°; volatilizes at 212°. Nitric acid converts it into ambreic acid. This acid combines with the bases, and resembles cholesteric acid.

AMIDINE. A substance found in starch paste that has been long exposed to the atmosphere, and also formed immediately by the action of hot water. (Saussure, Caventou.) Its properties are intermediate between those of starch and gum.

AMILENE. *Prep.* When the oil of potato spirit is repeatedly distilled with anhydrous phosphoric acid, an ethereous liquid, possessing a peculiar aromatic odor, is obtained, which has been called amilene by Cahours.

AMMELIDE. A white powder, possessing some peculiar properties, discovered by Liebig. *Prep.* It is prepared by dissolving melam, melamine, or ammeline, in strong sulphuric acid, adding alcohol, and washing the precipitate with cold water. It is purified by resolution in dilute nitric acid, and precipitation by carbonate of ammonia.

AMMELINE. *Prep.* Dissolve melam in boiling dilute muriatic acid, evaporate and crystallize. Dissolve the crystals in pure water, and precipitate with ammonia. *Remarks.* A weak alkaline base, discovered by Liebig. It consists of very fine needles, having a silky lustre.

AMMONIA. *Syn.* VOLATILE ALKALI. ALKALINE AIR. GASEOUS AMMONIA. AZOTURETED HYDROGEN. Pure ammonia is an incondensable colorless gas, possessing great pungency and acridness, and powerful alkaline properties. Water readily absorbs about 500 times its volume of this substance, and in this state forms strong liquid ammonia, which, when much more dilute, is popularly known as spirits of hartshorn, or water of ammonia. As usually met with in the form of a semi-crystalline whitish mass, commonly called smelling salts, it is combined with carbonic acid and water, forming a sesquicarbonate of this base.

Hist., Sources, &c. Ammonia, in combination with acids, is frequently found ready formed in nature; but that met with in commerce is an artificial production. It is found, in variable quantities, among the saline product of volcanoes, in sea water, in bituminous coal, and in the atmosphere, especially that of large towns. The minute stellated crystals sometimes found on dirty windows in London and other populous cities consist of sulphate of ammonia. (Brande.) Ammonia was originally brought from Egypt, where it was obtained by sublimation, under the form of sal ammoniac, from the soot produced by burning camel's dung. It was afterwards procured from putrid urine by distillation; but at the present day it is chiefly prepared from the ammoniacal liquor of the gas-works, and the manufactories of ivory black, animal charcoal, &c. In these places a larger quantity of crude ammoniacal liquor is obtained, to which either sulphuric or muriatic acid is added, by which it is converted into a salt, which may be obtained nearly pure by evaporation, crystallization, and subsequent sublimation Other processes have been adopted for the preparation of the principal salts of ammonia, viz., its sulphate, carbonate, and muriate, some of which have been patented, but none of these have got into general use.

Prep. Mix unslaked lime with an equal weight of sal ammoniac, both dry and in fine powder; introduce the mixture into a glass retort, and join the beak by a collar of Indian rubber to a glass tube about 18 inches long, which must lie horizontally, and have its beak bent up ready to be placed under a glass jar, on the shelf of a mercurial pneumatic trough. Heat being applied by means of a spirit-lamp, and the air contained in the apparatus having been expelled, the gas may be collected for use. Ammonia cannot be dried by means of muriate of lime.

Use. It is employed in several chemical processes; absorbed by water it forms liquor of ammonia, spirits of hartshorn, &c., which see.

Tests and Char. Ammonia is easily recognised by—1. Its pungent odor. 2. By turning vegetable blues green and yellows brown, but which soon regain their previous colors, especially on the application of heat. 3. By producing dense white fumes when brought in contact with those of muriatic acid, as for instance, by holding the stopper moistened with the latter over the former. *The salts of ammonia* may be known by the following properties:—1. The exhalation of ammoniacal gas (recognised by its odor) when mixed with caustic potassa, or soda. 2. Dropped into a solution of chloride of platinum, they produce a yellow precipitate. They are mostly *soluble in water, volatile*, and crystallizable.

Estimation. This is usually performed by putting a given weight of the sample into a small retort, the end of which is made to dip into a vessel containing dilute muriatic acid. A strong solution of caustic potassa is then poured into the retort, and heat applied by means of a small spirit lamp. When all the ammonia is distilled over, the acid solution must be evaporated to dryness and weighed, and from the quantity of the muriate thus found, the weight of pure ammonia will be known; 54 parts of the former being equivalent to 17 of the latter. If the article for examination be a solid substance (as a salt) it may be dissolved in water or dilute acid before being put into the retort.

AMMONIA, ACETATE OF. *Prep.* I. Mix together equal parts of sal ammoniac and acetate of potassa, and distil; binacetate of ammonia passes over into the receiver, as an oily liquid, which on cooling forms a radiated crystalline mass. By passing dry ammoniacal gas into this salt, melted by a gentle heat, it is transformed into the neutral acetate, and becomes solid and inodorous.

II. By saturating strong acetic acid with am

monia, and evaporating over sulphuric acid in vacuo, crystals of acetate of ammonia may be obtained.

Prop. Very soluble both in alcohol and water; very deliquescent.

AMMONIA, ACETATE, SOLUTION OF. *Syn.* MINDERUS SPIRIT. LIQUID ACETATE OF AMMONIA. WATER OF ACETATE OF AMMONIA. *Prep.* Saturate distilled vinegar with carbonate of ammonia.

Proportions.

	Sesquicarbonate of ammonia.	Distilled vinegar.
Lond. Ph. .	℥ivss	4 pints.
Edin. " .	℥j	f℥xxiv (s. g. 1·005)
Dub. " .	1 part.	about 30 parts.

Prop. Colorless; taste slightly urinous; neutral to litmus and turmeric paper; when concentrated by heat and mixed with oil of vitriol, it emits the fumes of vinegar, and those of ammonia, when mixed with caustic alkali or liquor of potassa in excess.

Use, Dose, &c. It is a very common febrifuge and diaphoretic, and an excellent *aperient* saline liquor. Taken warm in bed, it generally proves a powerful *sudorific;* and as it operates without heat, it is used in febrile and inflammatory disorders, where medicines of the warm kind, if they fail of producing sweat, aggravate the disease. Its action may likewise be determined to the kidneys, by walking about in cool air. The common dose is half an ounce, either by itself or along with other medicines adapted to the intention. Externally it is frequently used as a collyrium in chronic ophthalmia: 1 oz. to 9 oz. of water.

Remarks. It is very necessary to avoid an excess of ammonia, as its presence would prove in many cases injurious, especially in eye-waters. *A very trifling* excess of acid is preferable. The point of saturation is known by the effervescence becoming feeble on adding more ammonia, and the liquor being neutral to turmeric and litmus paper.

AMMONIA, SOLUTION OF ACETATE OF, (CONCENTRATED.) *Prep.* Saturate acetic acid, sp. gr. 1·038, with sesquicarbonate of ammonia in powder; about 2½ lbs. of the latter to 1 gallon of the former.

Remarks. The same precautions are necessary to produce a neutral solution as in the previous article. This article has a great demand in the wholesale drug trade, under the name of concentrated liquor of acetate of ammonia, (liq. ammon. acet. conc.) It is very convenient for dispensing. fʒj added to fʒvij of water, forms the liquor ammoniæ acetatis of the L. Ph.

AMMONIA, ARSENIATE OF. *Prep.* Saturate a strong solution of *arsenic* acid with the liquor of sesquicarbonate of ammonia; evaporate and crystallize. *Remarks.* A binarseniate may also be formed by adding an excess of acid.

AMMONIA, ARSENITE OF. *Prep.* Dissolve sesquicarbonate of ammonia in a hot and strong solution of *arsenious* acid, until saturation is produced; evaporate as last. *Use.* To make the arsenite of iron. Its properties and action are similar to those of arsenite of potash.

AMMONIA, ARGENTO-CHLORIDE OF. *Syn* AMMONIO-CHLORIDE OF SILVER. *Prep.* Expose well-washed and freshly precipitated chloride of silver to the action of ammoniacal gas, by placing a small cup containing liquor of ammonia, in an evaporating basin containing the chloride, and covering the whole with a sheet of glass or writing paper. After the lapse of a few hours, digest the precipitate in liquor of ammonia, sp. gr. ·880, gradually applying a gentle heat until at length the water boils; then remove the flask from the fire and allow it to cool, when crystals will form. These must then be collected, washed with a little cold liquor of ammonia, and dried by pressure between blotting-paper. *Caution. This article should only be prepared in small quantities at a time, as a brown fulminating powder, of the most dangerous description,* is not unfrequently thrown down from the liquor, and has sometimes led to accidents.

AMMONIA, BENZOATE OF. *Prep.* Dissolve pure benzoic acid in strong liquor of carbonate of ammonia, until the latter is saturated, applying (cautiously) a gentle heat; cool and crystallize. *Uses, &c.* As a chemical reagent.

Remarks. When the solution is boiled for a short time, and abandoned to spontaneous evaporation, crystals of acid benzoate of ammonia are deposited.

AMMONIA, BIMALATE OF. *Prep* Add a strong solution of malic acid to another of neutral malate of ammonia; cautiously evaporate and crystallize. *Prop.* Large crystals; taste, acid and agreeably saline; very soluble in water.

AMMONIA, CARBONATE OF. *Syn.* SUBCARBONATE OF DITTO. SESQUICARBONATE OF DITTO. VOLATILE SAL AMMONIAC. BAKER'S SALT. VOLATILE SALTS. PREPARED AMMONIA. AMMONIÆ SESQUICARBONAS, (P. L. and E.) AMMONIÆ CARBONAS, (P. D.) CARBONATE D'AMMONIAQUE, (*Fr.;*) KOHLENSAURES AMMONIAK, (*Ger.*) This is the substance popularly known as "*smelling salts.*"

Prep. I. Sal ammoniac 1 lb.; dried chalk 1½ lb. *Proc.* Pulverize the ingredients separately, then mix and sublime with a gradually increasing heat, (L. and E. Ph.) *Remarks.* The above are the proportions of the London and Scotch Colleges; they are as 2 to 3. The D. Ph. directs equal quantities of dried carbonate of soda and sal ammoniac. On the large scale this salt is prepared as follows.

II. Sal ammoniac, or pure commercial sulphate of ammonia, and chalk, equal parts, both dry and in powder. Mix and sublime from an iron pot, into a long earthen or leaden receiver, well cooled.

Remarks. The receiver is usually fitted with a moveable lead cover, secured by a water joint, and has an open lead pipe in the bottom, to allow the liquid products of the distillation to drain off into a second receiver. When made of the *impure* sulphate of ammonia, it must be resublimed in iron pots, furnished with leaden heads kept cool. A little water is commonly introduced into the subliming pots, to render the product translucent The heat is usually applied by means of a common furnace, but a steam or water bath is preferable, as the temperature required for this purpose does not exceed 200° F.

In the above processes the salt is formed by the double decomposition of the ingredients, a muriate or sulphate of lime being left in the retort, and

carbonate (sesqui-) of ammonia passing over into the receiver. It is commonly called a carbonate, but it is properly a sesquicarbonate, containing 1½ atom of carbonic acid and 1 atom of ammonia, besides combined water. (Phillips, Rose, Thompson.) As it is usually met with, *its* composition is variable, owing to the action of the atmosphere, &c. The chemically pure carbonate of ammonia can only be prepared by bringing together perfectly pure and dry carbonic acid and ammoniacal gases. Such is the competition at present existing in the ammonia trade, that this salt may be bought of very fine quality at 5d. a pound, in quantity. *Prop.* Soluble in 4 parts of cold water; but boiling water and alcohol decompose it, with the evolution of carbonic acid gas. By age or exposure to air, the surface assumes an opaque white color, from a portion of the ammonia flying off, and the remainder being converted into a bicarbonate.

Tests and Char. It is recognised in the same way as ammonia, and it is known to be a carbonate by giving a white precipitate with chloride of barium.

Uses. Much used by bakers, especially in their fancy goods, and to make extemporaneous bread and pastry; and by the chemist and pharmaceutist for the preparation of many of the salts of ammonia. As a medicine it is stimulant, antacid, diaphoretic, and antispasmodic. *Dose.* 5 to 15 grs. in pills or solution, (in hysteria, dyspepsia, heartburn, or chronic rheumatism.) A plaster made of 1 part of powdered carbonate of ammonia, and 3 parts of extract of belladonna, and spread upon leather, is used for allaying rheumatic pains. Sesquicarbonate of ammonia is also used to make an effervescing saline draught.

20 grs. of sesquicarbonate of ammonia, in solution, should be used, to either—	f36 of lemon juice, 24 grs. of citric acid, or 25 grs. of tartaric acid.

With the addition of a few drops of any aromatic essential oil, as lavender, bergamotte, &c. It is much used as a smelling salt in cases of fainting, &c.

AMMONIA, CARBONATE. (SUPER, OR BICARBONATE.) *Prep.* (Dub. Ph.) Dissolve carbonate of ammonia in water, and pass a stream of carbonic acid gas through it, until effervescence ceases. Dry the crystals without heat, and preserve in stoppered bottles. (See CARBONIC ACID.) *Remarks.* After the ammoniacal solution is thoroughly saturated with gas, evaporation must be conducted with *a very gentle heat,* when small prismatic crystals will form, having neither smell nor taste.

Prop., Uses, &c. Similar to the sesquicarbonate, except being devoid of smell. *Dose.* 6 to 24 grains.

AMMONIA, CITRATE. *Prep.* I. (*Extemporaneous.*) Saturate lemon juice with carbonate of ammonia, about ʒj of the latter to f℥ij and ʒij of the former.

II. (*Crystals.*) Saturate a solution of pure citric acid as above; evaporate and crystallize, (about 7 parts of acid to 6 of sesquicarbonate of ammonia.)

Uses, &c. A solution of the crystals is employed as a chemical reagent; the 1st form is used as a mild saline aperient and diaphoretic in febrile disorders.

AMMONIA, CYANATE OF. *Syn.* UREA. *Prep.* Mix 28 parts of perfectly dry ferro-cyanide of potassium with 14 parts of black oxide of manganese, both pure and in fine powder; then place them on a smooth iron plate, and heat them to a dull red, over a charcoal fire. When the mass begins to burn, it must be frequently stirred; after which cool and dissolve in cold water, filter and add 20½ parts of dry sulphate of ammonia, and decant the clear from the precipitated sulphate of potassa. Concentrate at a heat below 212°, again decant, evaporate to dryness, and digest in boiling alcohol of 80%; crystals of urea will be deposited as the solution cools. (Liebig.) *Prod.* 4 oz. of perfectly colorless and beautifully crystallized urea, from 1 lb. of the ferro-cyanide of potassium.

AMMONIA, HYDROSULPHURET OF. *Syn.* HYDROSULPHATE OF AMMONIA. BOYLE'S FUMING LIQUOR. BEGUIN'S SULPHURETED SPIRIT. HEPATIZED AMMONIA. SULPHURET OF AMMONIA. *Prep.* Reduce 5 parts of sulphuret of iron to coarse powder, put it into a retort, and pour thereon 7 parts of sulphuric acid, diluted with 32 parts of water, and pass the gas evolved through 4 parts of the strong liquor of ammonia, applying a gentle heat towards the end of the process.

Remarks. This operation is best conducted in a Woolf's apparatus, putting into the first bottle a little water, into the second, the liquor of ammonia, and into the third, some milk of lime to absorb the superfluous gas, and prevent its escape into the apartment. *This gas* is sulphureted hydrogen, which is not only very fœtid, but poisonous.

Prop. The hydrosulphuret of ammonia, when quite pure, is a gaseous body, readily absorbable by water, forming a transparent solution. It is this gas which constitutes the nauseous effluvia evolved from privies, and decomposing animal matter. *Dose.* 5 drops and upwards, mixed with water, and instantly swallowed to prevent decomposition, in diabetes. It is principally employed by the chemist as a test liquor for metals.

Ant. When this liquid is swallowed in large doses it acts as a violent poison. Dilute solution of chlorine, or the chloride of lime or soda, followed by a powerful emetic, or the stomach-pump, are the best antidotes. When the gas has been respired, free exposure to fresh air, and copious affusions of cold water, with moderate draughts of brandy and water, and the use of the smelling-bottle, (ammoniacal,) should be adopted.

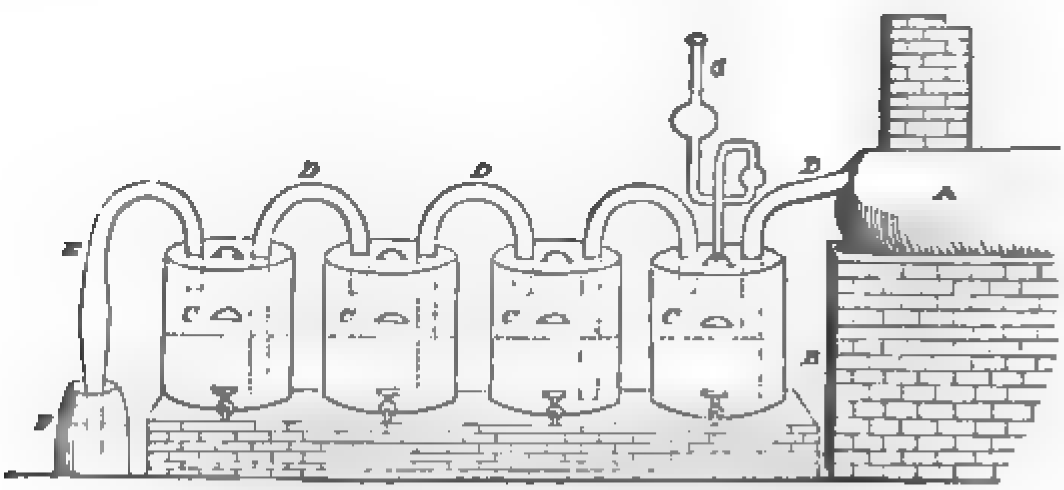
AMMONIA, LIQUOR OF. *Syn.* WATER OF AMMONIA. SOLUTION OF AMMONIA. WATER OF CAUSTIC AMMONIA. DISSOLUTION D'AMMONIAQUE (*Fr.*) LIQUORE DI AMMONIACO (*Ital.*) ATZENDER AMMONIUM-LIQUOR (*Ger.*) *Prep.* I. (*Liquor ammoniæ,* P. L.) *Ing.* Newly-burnt lime ℥viij; sal ammoniac, in small lumps ℥x; water 2 pints *Proc.* Put the lime into a retort and slake with a little water, then add the sal ammoniac, and the remainder of the water; distil f℥xv of the solution with a gradually increased heat into a *well-cooled* receiver. The sp. gr. should be 0·960.

II. (*Aqua ammoniæ fortior, and aqua ammon* P. E.) Both these articles are prepared by one process, by using a second receiver containing

double the quantity of water in the 1st. Sp. gr. 0·880 and 0·960. The proportions are equal parts of lime and sal ammoniac.

III. (*Aq. ammon. caustica.* D. Ph.) The specific gravity is 0·950.

IV. *On the commercial scale* this article is prepared from a mixture of about equal parts of quicklime and sal ammoniac, or sulphate of ammonia, which are heated together in an iron cylinder or retort, connected with a refrigerator, consisting of a row of stone bottles with double necks containing water, and kept very cold. The arrangement of this apparatus is represented below, which, with the accompanying references, will explain itself



A, Cylindrical Iron Retort.
B, Furnace for ditto.
C C C C, Stoneware Receivers.
D D D D, Connecting Pipes.
E F, Waste Pipe and Receiver.
G, Safety Tube

There are two methods of proceeding in mixing the ingredients: the one is to mix the dry ingredients together, and to drive over the dry gas into water; the other is first to slake the lime with a little water, then to add the sal ammoniac, and mix the whole to a pap before applying heat. In either case a proportionate quantity of water is put into the condenser, and the operation is nearly similar, but the latter method requires the least heat.

Remarks. Whatever form may be adopted to prepare liquid ammonia, it is absolutely necessary to keep the receivers as cool as possible for the purpose of promoting the absorption of the gas, and to prevent its loss. On the small scale the glass receivers or bottles should be surrounded with ice and furnished with a safety tube to prevent accidents. The water contained in the first bottle will be the strongest, if it be kept well cooled, and the others will progressively decrease in strength. By mixing the contents of one bottle with another, water of almost any strength may be made. This article is now seldom made by the druggist on the small scale, the large chemical manufactories supplying it at very low rates, and of very superior quality. In the shops, liquor of ammonia is kept of two or three strengths: one of a sp. gr. of ·880, for dissolving essential oils and filling smelling-bottles, &c.; another at 0·960, liq. of ammonia, P. L.; and a third about the strength of common spirits of hartshorn, for which it is sold. 1 measure of the first mixed with 3 measures of distilled water will make a water of about 0·970, and with only 2 measures of water, one of about 0·960. I have known the strongest sold so low as 9d. per lb., and the last at 1½d. *Caution.* It should be kept in well-stoppered bottles in a cool cellar.

Props., Uses, &c. Ammonia-water is stimulant, antacid, diaphoretic, and rubefacient. *Dose.* 5 to 20 drops, mixed with water. It is seldom used internally. It enters into the composition of several valuable external remedies, and is employed in many chemical operations.

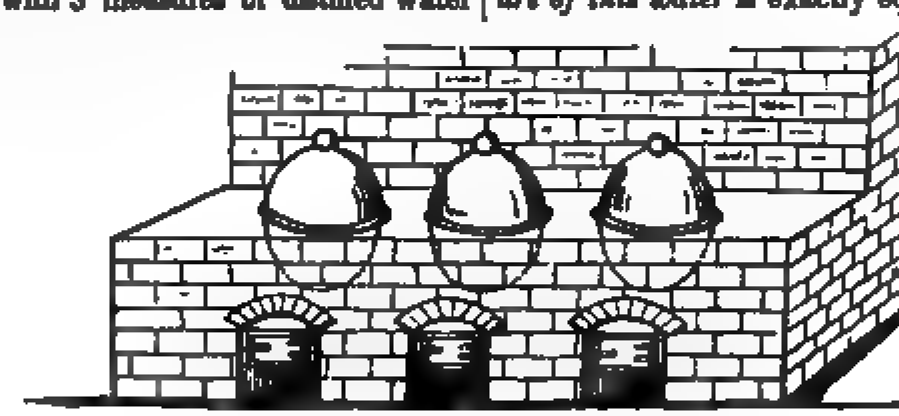
Pur. It should neither effervesce with acids, nor form a precipitate with lime, water, or chloride of calcium. When neutralized with nitric acid, neither nitrate of silver, oxalic acid, nor sesquicarbonate of ammonia, should produce any precipitate.

Ant. When the fumes have been inhaled, expose the patient to a current of fresh air, and when the liquid has been swallowed, administer vinegar or lemon-juice mixed with water.

Strength. The usual method of ascertaining the strength of liquid ammonia is by taking its specific gravity; before this is done, however, it is best to test it for its purity, as the presence of foreign matter will alter its density. (See ALKALIMETRY and AMMONIMETRY.)

AMMONIA, LIQUID, FOR TESTING. *Syn.* HENRY'S PURE AMMONIA WATER. *Prep.* Add distilled water to pure liquid ammonia, until its sp. gr. be exactly 0·970.

Use. For testing, in acidimetry, &c. *One measure of this water* is exactly equal to *one measure*



of sulphuric acid, sp. gr. 1·135; *one* measure of *nitric acid*, sp. gr. 1·143, and one measure of muriatic acid, sp. gr. 1·074. Useful in assaying waters.

AMMONIA, MURIATE OF. *Syn.* HYDROCHLORATE OF AMMONIA. SAL AMMONIAC. CHLORIDE OF AMMONIUM. CHLORO-AMIDIDE OF HYDROGEN. *Hist.* This substance is said to have been known to antiquity; it was formerly prepared in Egypt by the sublimation of the soot from camel's dung, which yields from ⅙ to ¼ its weight. (See AMMONIA.) The sal ammoniac of commerce is now wholly prepared at the great chemical works, and never by the small consumer, by whom it is merely occasionally refined or purified.

Prep. The crude ammoniacal salt of the gas-works is placed in iron pots, lined with clay, and a leaden dome or head adapted, and heat applied until the whole has sublimed. When the crude salt is a sulphate, it is mixed with a sufficient quantity of muriate of soda before sublimation, and the sal ammoniac is formed by the double decomposition of the ingredients. The preceding figure represents the arrangement of the pots and furnace, which was adopted a few years since at the Westminster gas-works.

The preparation of sal ammoniac from bone-spirit salt is nearly similar.

Prop. The sal ammoniac of commerce is found under the form of large hemispherical, cup-like cakes or masses, having a semi-crystalline texture, and varying in weight from 100 to 1000 lbs.

Use. It is much used in the arts, especially in the working of metals and in dyeing; it is also employed in large quantities to give a factitious pungency to snuff; in chemistry to form frigoric mixtures, &c., and in medicine, it is given as a diuretic, stimulant, and tonic. *Dose.* 5 to 20 grs. (combined with bark, in agues.) 1 oz. to half a pint of water forms a good chilblain lotion.

Pur. It forms a clear and colorless solution with water, and wholly volatilizes by heat. Mixed with lime or caustic potassa, it evolves the pungent odor of ammonia; it gives a white curdy precipitate with nitrate of silver.

Remarks. The sal ammoniac of commerce is generally sufficiently pure for all the purposes of the arts, but when wanted of greater purity, it may be broken into pieces and re-sublimed from an earthenware vessel into a large receiver of earthenware or glass, in which state it is known as "flowers of sal ammoniac," from being in fine powder. Chemically pure hydrochlorate of ammonia may be preparedby adding the pure carbonate of ammonia to dilute hydrochloric acid until saturated.

AMMONIA, NITRATE OF. *Syn.* NITRATE OF OXIDE OF AMMONIUM. NITRUM FLAMMANS. NITRUM SEMI-VOLATILE. *Prep.* Dilute nitric acid with 3 times its weight of water, then gradually add sesquicarbonate of ammonia in powder, to saturation; evaporate and crystallize.

Uses, &c. This salt is principally employed for the preparation of nitrous oxide, or laughing gas, of which nearly 3 cubic feet may be procured from 1 lb. (Davy.) It forms a very convenient "freezing mixture" with water, and may be used for this purpose any number of times by simply evaporating the solution to dryness, when the salt will be obtained unaltered, ready for another operation. *Dose.* 20 to 30 grs., as a febrifuge, but it appears worthless in this respect. *Remarks.* Nitrate of ammonia crystallizes in beautiful hexagonal prisms, when the process is conducted at a heat not exceeding 100° F., but at 212°, in long silky fibres or needles. When dried at 300°, it forms a compact white mass. The first is called *prismatic*, the second *fibrous*, and the third *compact* nitrate of ammonia.

AMMONIA, OXALATE OF. (AMMONIÆ OXALAS, P. E.) *Prep.* Oxalic acid ℥iv, water 4 pints, sesquicarbonate of ammonia ℥viij. *Proc.* Dissolve the acid in the water, then add the ammonia in powder; evaporate and crystallize.

Remarks. The above is the form of the Ed. Ph., but all that is required is to saturate a solution of oxalic acid with ammonia. It is used as a test for lime, with which it produces a white precipitate soluble in nitric acid.

AMMONIA, WATER OF OXALATE OF. *Prep.* Dissolve oxalate of ammonia in 10 or 12 times its weight of pure water. *Use.* As above.

AMMONIA, SUCCINATE OF. *Prep.* Saturate a solution of succinic acid with ammonia, (liq. or carb.,) evaporate and crystallize. *Use.* As a test for iron. It is said to be antispasmodic.

AMMONIA, SULPHATE OF. *Syn.* SULFAMIDE. SECRET SALT OF GLAUBER. SULPHATE OF OXIDE OF AMMONIUM. OXYSULPHION OF AMMONIUM. SECRET SAL AMMONIAC. AMMONIÆ SULPHAS. (*Lat.*) The manufacture of the crude sulphate has been already described; the pure salt is made as follows:

Prep. Saturate dilute sulphuric acid with ammonia; evaporate and crystallize.

Uses, &c. It is diuretic and aperient, but has been little used in medicine. *Dose.* 5 to 30 grains. The crude sulphate forms an excellent manure. (See MANURES.)

AMMONIACAL LAVENDER. *Syn.* AMMONIACAL ALCOHOLATE OF LAVENDER, (P. Cod.) *Prep.* Dissolve 1 oz. of English oil of lavender in 2 lbs. of spirits of ammonia. *Use.* Stimulant; as a scent in fainting.

AMMONIMETRY. *Syn.* AMMONIOMETRY. The operation by which the strength of liquid ammonia or ammonia water is determined.

Proc. The strength of liquid ammonia is best found from its specific gravity, which may be easily ascertained by an hydrometer, or sp. gr. bottle. (See SPECIFIC GRAVITY.) When the content of ammonia per cent. may be found by mere inspection of either of the following tables, or approximately by deducting the sp. gr. expressed in three integers from 998, and dividing the remainder by 4; the quotient will give the per centage very nearly. (Ure.) This rule may be employed for such sp. gr. as are not contained in the tables.

I. TABLE of the Per Centage of Pure Ammonia, in Water of Ammonia of the specific gravity 0·8750 to 0·9692. By Sir H. DAVY.

Sp. Gr.	Ammonia.	Water.
0·8750	32·50	67·50
0·8875	29·25	70·75
0·9000	26·00	74·00
0·9054	25·37	74·63

Sp. Gr.	Ammonia.	Water.
0·9166	22·07	77·93
0·9255	19·54	80·46
0·9326	17·52	82·48
0·9385	15·88	84·12
0·9435	14·53	85·47
0·9476	13·46	86·54
0·9513	12·40	87·60
0·9545	11·56	88·44
0·9573	10·82	89·18
0·9597	10·17	89·83
0·9619	9·60	90·40
0·9692	9·50	90·50

II. Table of the Per Centage of Pure Ammonia, and of Ammonia Water of 0·9000 in Water of Ammonia of the specific gravity 0·9000 to 0·9945. By Dr. Ure.

Water of 0·900.	Ammonia in 100.	Water in 100.	Sp. Gr. by experiment.
100	26·500	73·500	0·9000
95	25·175	74·825	0·9045
90	23·850	76·150	0·9090
85	22·525	77·475	0·9133
80	21·200	78·800	0·9177
75	19·875	80·125	0·9227
70	18·550	81·450	0·9275
65	17·225	82·775	0·9320
60	15·900	84·100	0·9363
55	14·575	85·425	0·9410
50	13·250	86·750	0·9455
45	11·925	88·075	0·9510
40	10·600	89·400	0·9564
35	9·275	90·725	0·9614
30	7·950	92·050	0·9662
25	6·625	93·375	0·9716
20	5·300	94·700	0·9768
15	3·975	96·025	0·9828
10	2·650	97·350	0·9887
5	1·325	98·675	0·9945

AMMONIACUM. A gum resin, the inspissated juice of the dorema ammoniacum. It is stimulant and expectorant, and is much used in catarrhs. *Dose.* 10 to 30 grs. in pills, or diffused through water.

AMMONIACUM, STRAINED. *Prep.* I. Boil the ammoniacum with water, until it forms an emulsion or milk, then strain it through canvass; boil the refuse a second time with more water; mix the liquors, and evaporate to a proper consistence.

II. Place the gum on a sieve or canvass strainer, and put it on the top of a copper pan, containing a little boiling water. The steam will soften the gum, which will then run through, leaving the impurities behind; evaporate as before.

Remarks. The first method is that usually adopted in trade; but the second preserves the odor of the gum much better. *Use.* To make the plaster of ammoniacum, and the plaster of ammoniacum and mercury.

AMNIOTIC ACID. Vauquelin and Buniva gave this name to allantoin, which, by some unaccountable mistake, they represent to have found in the liquor amnii of the cow, instead of the fluid of the allantois, as shown by Lassaigne.

AMULETS. Substances worn about the person to protect the wearer against some real or imaginary evil. Their protective power depends entirely on the imagination; they are therefore now wholly discarded, except by the most superstitious and ignorant. Camphor is frequently worn as a protective against fever.

AMYGDALINE. Discovered by Robiquet and Boutron Charlard. *Source.* The bitter almond and the laurocerasus.

Prep. Powder bitter almonds, from which the oil has been thoroughly expressed, and boil it repeatedly in alcohol of 93 or 94§; mix the several tinctures, and distil off the alcohol; mix the sirupy residuum with water, add a little yeast, and ferment; after the fermentation has ceased, evaporate in a water bath to the consistence of a sirup, and add alcohol of 94§; collect the precipitate, drain well, and purify by repeated re-solutions and crystallizations. *Prod.* 3 to 4§.

Prop., &c. *Form,* Silken crystalline scales; taste, sweet and nutty; scentless; soluble in water and *hot* alcohol. Its solution, mixed with milk of almonds, produces prussic acid and essential oil of almonds.

AMYGDALINIC ACID. A new acid discovered by Wohler and Liebig.

Prep. Dissolve amygdaline in baryta water, and boil the solution in a glass vessel as long as ammonia is evolved; then add dilute sulphuric acid until precipitation ceases; filter and evaporate the clear liquid in a water bath. *Prop., &c.* A colorless transparent acidulous mass; deliquescent in damp air, and soluble in water. With the bases it forms soluble salts but little known, called amygdalinates.

AMYLIC ACID. A new acid compound, first described by M. Tünnerman in Trommsdorff's 'Journal.' Its ultimate constituents are carbon 2·5, oxygen 3. It is but little known.

Prep. Three parts of muriatic acid are gradually added through a feeding tube, to one part each of starch, black oxide of manganese, and water, previously well mixed together and heated in a capacious tubulated retort, connected with a well-cooled receiver. The product is impure amylic acid, which should be saturated with carbonate of lime, and crystallized by gentle evaporation. This salt, decomposed by 73 per cent. of sulphuric acid, yields by distillation pure amylic acid.

Prop. It forms salts with the bases, which are mostly soluble and deliquescent, and possess the property of reducing the nitrate of silver and muriate of gold. It evaporates when gently heated, and gives out a sharp smell, resembling prussic acid.

ANACARDIUM INK. The cashew nut contains a fluid between the kernel and shell, which forms an excellent marking ink. On linen and cotton it turns gradually black, and is very durable. (Ure.)

ANALYSIS, (in Chemistry.) The resolution of any substance into its elements. It is divided into *qualitative* and *quantitative* analysis; and these again into *proximate* and *ultimate* analysis. The *first* consists in merely finding the components of a compound; the *second*, the components and the proportions of each of them; the *third*,

the proximate or compound constituents; and the *fourth*, the chemical elements of which it is composed. For success in chemical analysis a thorough acquaintance with the various properties of bodies is required, as well as an aptitude in applying this knowledge in discriminating them and separating them from each other. Judgment and expertness in manipulation are also essential. To enter fully into the subject of chemical analysis is not the object of the present work; nor would its size admit of such, even though every page of it were devoted to this subject. The reader will, however, find appended to each article of importance the most simple means of determining its *purity*, as well as detecting its presence in mixtures, and in some cases estimating its quantity.

ANATOMICAL PREPARATIONS, FLUID FOR. (*Objects of Natural History, &c.*) *Prep.* I. Saturate water with sulphurous acid, and add a little creosote.

II. Dissolve 4 parts of chloride of tin in 100 of water, to which 3 per cent. of muriatic acid has been added.

III. Dissolve 5 or 6 parts of corrosive sublimate in 100 of water, to which 2% of muriatic acid has been added.

IV. Mix together one part of ammonia water (strong) with 3 times its weight (each) of water and spirit of wine.

Remarks. These fluids are used by immersing the objects therein, in close vessels. The third formula is apt to render animal substances very hard.

ANCHOVIES, BRITISH. *Prep.* To a peck of sprats put two pounds of salt, three ounces of bay-salt, one pound of saltpetre, two ounces of prunella, and a few grains of cochineal; pound them all in a mortar, then put into a stone pan or anchovy barrel, first a layer of sprats, and then one of the compound, and so on alternately to the top. Press them down hard; cover them close for six months, and they will be fit for use, and will really produce a most excellent flavored sauce. *Remarks.* A large trade is done in this article, especially for making anchovy paste or sauce, when a little more coloring is added.

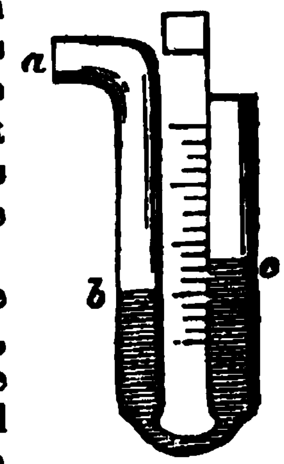
ANCHOVY POWDER. *Prep.* I. Pound anchovies to a paste, then rub them through a sieve, and add enough flour to make a dough, which must be rolled out into thin slices and dried for powdering.

II. Substitute British anchovies, and add coloring. *Use.* To make sauces.

ANCHUSIC ACID. This name has been given to the coloring principle of alkanet root, (the anchusa tinctoria,) but little is known respecting it. (See ALKANET ROOT.)

ANEMOMETER. An instrument for determining the force of the wind.

An excellent instrument of this sort which may be applied to determine the draught of a chimney as well, is the anemometer of Dr. Lind, the construction of which, by means of the annexed engraving, will be rendered familiar. *App.* The open end, *a*, is kept by means of a vane presented to the wind, which acting on the surface of the liquid (water) *b*, raises it in the arm *c*. The difference of the level of the fluid in the two arms of the instrument is the measure of the force of the wind. To estimate the draught of a flue or chimney, the arm *c* is placed in the chimney, and the orifice *a* in the apartment.



ANEMONINE. A substance noticed by Löwig and Fehling, extracted by hot alcohol from the anemone pulsatilla, nemorosa, and pratensis. By the action of baryta water on this substance, Löwig obtained a compound which has been called anemonic acid.

ANDERSON'S PILLS. *Prep.* Barbadoes aloes 2 oz.; jalap 1 oz., (both in powder;) oil of aniseed 2 drops; mix and beat them into a mass with sirup. *Dose.* 5 to 20 grains; purgative.

ANGELICA, CANDIED. *Prep.* Boil the fresh stalks in water, to remove their bitterness, then put them into a sirup boiled to a full candy height, and boiling hot; let them remain until nearly cold, when they may be taken out and dried. *Prop.* Cordial and stomachic.

ANGELICA, EXTRACT OF. I. (Dr. MOHR.) Macerate 2 lbs. of the bruised root in 1 gallon of rectified spirit of wine, for 7 days; strain and press; then macerate again in 1 gallon of proof spirit; filter each separately; mix and distil off the spirit; lastly, evaporate the remainder in a water bath to the consistence of an extract. *Remarks.* Quality very fine; odor and taste strongly balsamic.

II. Macerate 2 lbs. of bruised angelica root in 1 gallon of a mixture of equal parts of rectified spirit and water for 10 days, frequently shaking; then proceed as before. *Remarks.* Not so balsamic as the former.

ANGELICA, INFUSION OF. Dr. Mohr directs the use of hot water, or preferably wine. *Remarks.* An oil and water is also obtained from angelica, by distillation; a tincture is prepared, (with rectified spirit,) and pills are made of the extract.

ANGELIC ACID. During a recent analysis of angelica root, by L. A. Buchner, jun., he discovered a peculiar volatile acid, of a pungent sour smell, and biting acid taste; sometimes fluid and oleaginous, and sometimes crystallized in striated prisms. (Schmidt's Jahrb., Aug. 1842.)

ANGELICINE. A substance obtained from the root of angelica. The process is troublesome, and the product small.

ANGEL WATER. *Syn.* PORTUGAL WATER. *Prep.* Mix together 1 pint each of orange-flower and rose-water, ½ pint of myrtle water, ¼ oz. of essence of musk, and 1 oz. of essence of ambergris; shake them well up, and filter through white blotting-paper.

ANGOSTURA BARK. The true medicinal angostura or cusparia bark is brought from the West Indies; but a spurious and poisonous species is imported from the East Indies, and is frequently sold for or mixed with the former. The following tabular view of the characteristics of each will afford a ready means of detecting this fraud.

Tabular View of the Characteristics of the True and False Angostura Barks; drawn up by Dr. Pereira, from his own researches, and those of Guibourt, Fee, and others.

		True Angostura Bark.	Nux Vomica, or False Angostura Bark.
Form		Quills or flat pieces, straight or slightly bent	Quills or flat pieces; short; often very much twisted, like dried horn; arched backwards
Odor		Disagreeable	None, or very slight.
Taste		Bitter, afterwards somewhat acrid; persistent	Intensely bitter; very persistent.
Hardness and density		Bark fragile when dry; easily cut; light; tissue not very dense	Broken, or cut with difficulty; heavy; tissue compact.
Fracture		Dull and blackish	Resinous.
Epidermoid crust		Whitish or yellowish; insipid; unchanged, or rendered slightly orange red by nitric acid	Variable; sometimes a spongy rust-colored layer at other times whitish, prominent spots, more or less scattered or approximated. Nitric acid makes it intensely dark green or blackish.
Inner surface		Separable into laminæ; deepened by nitric acid	Not separable into laminæ; rendered blood red by nitric acid.
Infusion of the bark in 24 parts of water, with	Tinct. Litmus	Blue color destroyed	Slightly reddened.
	Sesquichloride of Iron	Flocculent dark grayish-brown precipitate	Clear yellowish-green liquor.
	Prussiate of Potash	No change; hydrochloric acid caused a yellow precipitate	Slight turbidness, not increased by hydrochloric acid.
	Nitric Acid	A small quantity makes the liquor cloudy; a large quantity makes it a transparent deep red	A small quantity makes the liquor clear and paler; a large quantity transparent red.

ANGOSTURIN. *Syn.* Cusparin. Saladin. Bitter Extractive. *Prep.* Digest bruised angostura bark in alcohol until the latter will take up no more; then filter and submit it to spontaneous evaporation. *Prop.* Dissolves in alcohol, water, and alkaline lyes; neutral; tincture of galls precipitates it from its solutions.

ANHYDROUS. (In Chemistry.) Without water; a term frequently applied to gases, salts, alcohol, acids, and some other substances, to express their existence in the *dry* state. The gases may generally be rendered anhydrous, by passing them through a tube containing very dry powdered chloride of calcium, and some of them by passing through strong sulphuric acid. Salts may generally be dried by cautiously submitting them to the action of heat; and alcohol, and many other volatile fluids, by careful distillation from chloride of calcium.

ANIMAL SUBSTANCES USED AS FOOD, PRESERVATION OF. Animal substances are preserved in various ways, among which may be mentioned—

1. *Exposure to the sun*, or in a stove, to as high a heat as possible without scorching them.

2. *Exposure to the frost* until they become frozen, and then keeping them in this state. Meat, fish, poultry, &c. are generally preserved in this way in the colder parts of North America, in Russia, and in many other parts of the world. In Lower Canada, the meat killed early in the winter is frequently kept in a frozen state for summer use, to prevent the necessity of killing during the hotter portions of the year. It remains perfectly fresh, tender, and good flavored.

3. *Salting in brine.* This method is both easy and effectual. The best plan is to dissolve about 4 lbs. of good salt in 1 gallon of water, for brine, and to immerse the meat therein, at the same time adding a few handfuls of undissolved large grained rock salt, more than it will dissolve, for the purpose of keeping up its strength. Three to ten days, depending on the size, is sufficiently long to keep the meat in the brine; when it is taken out it should be hung up to dry, packed in barrels with coarse-grained salt, or smoked, whichever may be desired. When the brine has been used for some time, it should be boiled with some more salt and 2 or 3 eggs, then skimmed and strained. Saltpetre added to brine gives the meat a red color, and brown sugar improves the flavor.

4. *Dry salting.* In many parts, as in Hampshire, Yorkshire, &c., the process of dry salting is adopted, which consists of merely well rubbing the salt, mixed with a little saltpetre, into the meat, and afterwards sprinkling some over it, and placing it on a board or trough in such a manner that the brine may drain off. Sometimes fresh meat is packed at once in casks, with the best *coarse-grained salt.*

5. *Pickling.* This plan is to steep the substance in vinegar, or a mixture of vinegar and beer. Fish is often served in this way.

6. *Pyroligneous acid* brushed over animal substances will keep them for any length of time. This acid imparts a smoky flavor; but pure acetic acid may be used instead. Before use, the substance should be washed or soaked in water.

7. *Immersion in olive oil.* Salmon and other fish are often preserved in jars of salad oil, well corked up, and cemented over.

8. *Potting.* Small birds, fish, cooked meat, &c. are frequently pounded to a paste, with spices and butter, and pressed into pots until nearly full, when melted clarified butter is poured over to about ¼ or ⅛ of an inch in depth. This plan is called "*potting.*"

9. *Smoking.* This is done on the large scale by hanging the articles up in smoking rooms, into which smoke is brought from dry wood fires, kindled in the cellar, for the purpose of allowing it to cool and deposite its cruder part, before it arrives at the meat. This process requires from six days to as many weeks to perform it properly, and is best done in winter. In farm-houses, where dry wood is burnt, hams, &c. are often smoked by

hanging them up in some *cool* part of the kitchen chimney. When the meat is cut into slices, or scored deeply with a knife, to allow the smoke to penetrate it, it is called "*buccaning*." This is frequently performed by hunters in the remoter parts of Europe, by placing the slices on a grating of sticks, about 3 or 4 feet high, over a fire made with the branches of trees, and continuing the drying and smoking until the meat be sufficiently cured.

10. *Jerking*. In some hot countries the meat, cut in thin slices, is dried in the sun, beat into a paste in a mortar, and pressed into jars for use. Sometimes meal or flour is added. This plan is called "jerking," or "charqui."

11. *For sea-stores*, a new and simple plan has been lately adopted. *Proc.* Immerse the meat, cut into slices of from 4 to 8 ounces each, for five minutes in a vessel of boiling water, and dry them on network, at a regular temperature of from 120° to 125° Fahr. Next evaporate the soup formed by washing the meat, to the consistence of a thick varnish, adding a little spice to flavor it; into this fluid immerse the perfectly dry pieces of flesh, and again expose them to the proper drying temperature. Repeat the operation of dipping and drying a second and a third time. *Remarks.* For use, the meat must be cooked in the usual way for boiling, &c. In this manner, meat may be preserved without salt, for 15 to 20 months.

12. *Skins are preserved by tanning*, or exposure to the action of oak bark and other astringents, until they are converted into leather; or by *tawing* them, which is somewhat similar.

Other methods have also been occasionally adopted for objects of natural history and anatomical preparations; as dilute spirit or weak solution of corrosive sublimate, both of which, however, harden the texture of animal substances considerably. This may be prevented in the former by adding a little liquor of ammonia. (See PUTREFACTION.)

ANIMATION, SUSPENDED. *Syn.* ASPHYXIA. *Causes.* Various; hence it has been divided into four varieties, viz.:

1. *From suffocation produced by hanging and drowning.*

2. *From suffocation produced by the inhalation of irrespirable gases or vapors, as the fumes of charcoal, fixed air, &c.*

3. *From strokes of lightning or electricity.*

4. *From extreme cold.* (Dr. Mason Good.)

No general rules can be given exactly suitable to each case; but the reader is referred to DROWNING. Whenever it is possible to procure medical aid, it should be immediately sought, as the delay of a single minute may put the case beyond the reach of assistance. The following valuable remarks on asphyxia, from the pen of an eminent physician, may, however, be well introduced here:

The treatment of asphyxia involves an attention both to the functions of respiration and to that of the true spinal marrow. The object, doubtless, is to effect a restoration of the respiratory and circulatory functions, the former of which has been arrested by the external conditions of the patient; the latter, by the contact of morbidly carbonized blood with the capillary vessels of the lungs. The first thing to be attempted is the restoration of warmth by active friction with warm hands, &c.; the second, the imitation of artificial respiration, by any means at hand, of which none is better, usually, than the action of alternate pressure and its relaxation, applied to the thorax and abdomen, so as to induce expiration first, and inspiration immediately by the play of the elasticity of the ribs. The third effort is made by suddenly dashing cold water on the face and general surface, previously warmed by the frictions, in the hope of inducing a more decided inspiration. Artificial respiration must be attended to, if these measures, very promptly enforced, fail; and unless the proper apparatus be present, the mouth of another person, of robust make, is to be applied to that of the asphyxiated person, covered with a handkerchief, the nostrils being closed. (Dr. Marshall Hall.)

ANISEED, COMPOUND SPIRIT OF. *Prep.* Aniseeds and angelica seeds, of each, 8 oz.; cassia bark and caraways, of each, ½ oz.; all bruised; proof spirit and water, of each, 1 gallon. *Proc.* Macerate for 3 or 4 days, then distil over 1 gallon.

II. Oil of aniseed 2 drachms; oil of angelica ½ drachm; oil of cassia 20 drops; oil of caraway 15 drops; proof spirit 1 gallon. Mix well.

Use. A pleasant cordial in flatulence, low spirits, &c. *Dose.* ½ oz. in water. Much used by some old ladies. *Remarks.* Should it be milky, shake it up with a tablespoonful of magnesia, and filter through blotting-paper.

ANISETTE DE BOURDEAUX. *Ing.* Aniseed 4 oz.; coriander and sweet fennel seeds, of each, 1 oz.; rectified spirit ½ gallon; water 3 quarts. *Proc.* Bruise the seeds, and macerate them for 2 days in the spirit and water; then draw over 7 pints, and add lump sugar 2 lbs.

II. Lump sugar 1½ lb.; oil of aniseed 12 drops; oil of cassia and caraway, of each, 5 drops; spirit, 60 u. p., 3 quarts. *Proc.* Rub a little of the sugar with the oils, then dissolve it in the spirit; add the water and filter through magnesia; lastly, dissolve the remaining portion of the sugar in the filtered liquor.

III. Good brandy 3 quarts; sugar 1¼ lb.; aniseed water 1 pint. As above. *Remarks.* An agreeable cordial.

ANNEALING. The process by which glass is rendered less frangible, and metals which have become brittle again rendered tough and malleable. *Glass* vessels, and other articles of glass, are annealed by being placed in an oven or apartment near the furnaces at which they are formed, called the "*leer*," where they are allowed to cool slowly, the process being prolonged according to their bulk. *Steel, iron, and other metals* are annealed by heating them and allowing them to cool slowly on the hearth of the furnace, or any other suitable place, unexposed to the cold. As a specimen of *unannealed glass*, the *Prince Rupert's drop* may be mentioned, and of unannealed *metals, common cast iron;* to each of which the reader is referred, in their alphabetical places.

ANNOTTO. A valuable coloring matter, imported into Europe in cakes, and usually made up in England into rolls, before sale. *Source.* The pellicles of the seeds of the bixa orellana. *Sol.* Alcohol, ether, volatile, and fixed oils, to each of which it imparts a beautiful orange color; very soluble in alkaline lyes, which darken it, and in

strong sulphuric acid, which turns it blue. *Remarks.* The best annotto is known as roll annotto; flag and egg annotto are not so much esteemed. *Use.* For dyeing, painting, coloring, varnishing, cheese-making, &c.

ANNOTTO, PURIFIED. *Syn.* ORELLINE. CONCENTRATED ANNOTTO. *Prep.* Boil annotto in a solution of pearlash, until it will dissolve no more; then add oil of vitriol, previously diluted with 20 times its weight of water, until no more coloring matter is thrown down, but not enough to make the liquor taste sour; wash the precipitate with a little cold water; then drain and dry it.

Remarks. This is the pure coloring matter of annotto, and possesses all the properties of the best annotto in a concentrated form.

ANNOTTO, COMMON. *Syn.* REDUCED ANNOTTO. ENGLISH ANNOTTO. *Ing.* Egg or flag annotto 24 lbs.; gum tragacanth, 10 lbs.; starch 6 lbs.; soap 1½ lb.; red bole, or Venetian red, 1 lb.; water q. s. *Proc.* Mix by heat in a copper pan, and form into rolls.

Remarks. Used for common purposes. Should it be attempted to pass this off for genuine annotto, the fraud may be detected by its partial solubility in alcohol.

ANNOTTO, CHOICE OF. Annotto should be chosen of a good flame color; brighter in the middle than on the outside. It should feel soft and smooth, and have a good consistence. It should possess a strong smell.

ANNOTTO DYE. *Prep.* Cut the annotto into small pieces, and boil it in a copper, with an equal weight of good pearlashes, then dilute with water to a proper color. *Process of dyeing.* Immerse the articles, previously rinsed in clean water, in the dye, and give them a good boil; then drain them out and rinse them well in clean water.

Remarks. Annotto is chiefly used for silks, to which it imparts a fine orange yellow color, the shade of which may be modified, by using different proportions of pearlash, and also by giving the stuff different mordants before putting it into the dye-bath.

ANODYNE. (From the Gr. ἀ, without, and ὀδύνη, pain.) A medicine which allays pain. Among the principal anodynes may be mentioned opium, morphia, camphor, and other medicines of the same kind. "The constant use of anodynes begets their necessity." (W. Cooley.)

ANODYNE NECKLACES, are formed of the roots of hyoscyamus, Job's tears, allspice steeped in brandy, jumble beads, or elk's hoof, to suit the fancies of the prescribers. *Use.* To procure easy dentition in children, and sleep in fevers. (Bah!)

ANODYNE, INFANTILE. *Prep.* Sirup of red poppies 1 oz., aniseed water 3 oz., brandy or spirit of wine ½ oz.; mix. *Use.* An excellent anodyne for infants. *Dose.* A small teaspoonful as required.

ANODYNE, MARTIAL. *Prep.* Dissolve ammoniated iron in water, and precipitate with liquor of potassa; wash and dry. *Remarks.* An obsolete preparation. It is sesqui-oxide of iron.

ANODYNE, MINERAL. An old preparation formed by dissolving diaphoretic antimony in water, and evaporating to dryness.

ANO ZABAGLIONE. *Prep.* Put 2 eggs, 3 teaspoonfuls of sugar, and 2 small glasses of marsala, into a chocolate cup, over the fire, and keep it rapidly stirred, until it begins to rise and hardens, then serve it up in glasses. *Remarks.* A pleasant Italian receipt for a cold: very nutritious.

ANTACIDS. Medicines that neutralize the acid of the stomach, and thus tend to remove heartburn, dyspepsia, and diarrhœa. The principal antacids are the carbonates of potassa, soda, ammonia, lime, and magnesia. Ammonia is the most powerful, and when the acidity is conjoined with nausea and faintness, is the best; when great irritability of the coats of the stomach exist, *potash* is preferable; when accompanied with diarrhœa, *carbonate of lime*, (prepared chalk;) and when with *costiveness*, *magnesia*. (See ABSORBENTS.) The *dose* of the *carbonates* of *potassa* and *soda* in powder is *half a teaspoonful*, of *chalk*, *a teaspoonful*, of *magnesia*, *a dessert spoonful*, and of *carbonate of ammonia*, 10 *grs.*, or a teaspoonful of the solution. All these are taken in water.

ANTHELMINTICS. Medicines that destroy worms. *List.* Among the principal anthelmintics are, *calomel*, *tin powder*, *castor oil*, *oil of turpentine*, *cowhage*, and *gamboge*. *Remarks.* A good plan for removing worms from children, is to give 3 to 5 grs. of calomel in sugar, overnight, and a dose of castor oil the next morning. The motions should be observed, and if worms be found, the same treatment may be followed once a week, until they are wholly removed.

ANTHIARINE. *Syn.* ANTIARINE. The active principle of the antiaris toxicaria, or upas poison-tree of Java. It is extracted from the upas poison by alcohol, and is obtained under the form of small crystalline scales. It is a frightful poison, to which no antidote is known.

ANTHRAKOKALI. A remedy recommended by Dr. Polya in scrofula and chronic rheumatism. *Prep.* Mix in an iron basin over the fire, 160 parts of powdered coal with 192 parts of strong boiling solution of caustic potassa. Stir until converted into a homogeneous black powder. *Dose* 1 gramme with ·25 gramme of powdered liquorice, 3 or 4 times daily.

Remarks. What remedy next? *Answer.* (See FULIGOKALI.) This is as bad as curing hydrophobia with the top of the snuff of a mould candle, or consumption with naphtha.

ANTHRAKOKALI, POMMADE OF. *Prep.* Anthrakokali in fine powder 1 part, lard 30 parts; mix.

Remarks. "*Said*" to have been tried by Dr Gibert at the Hôpital St. Louis, on 24 cases of cutaneous disease, many of which were cured, and in all, the symptoms were ameliorated.—?

ANTHRANILIC ACID. An acid discovered by Fritzsche, and prepared from indigo.

Prep. Dissolve indigo in a hot solution of pure potassa, sp. gr. 1·35, and add powdered peroxide of manganese, until the liquid on dilution and exposure to the air ceases to form indigo blue. It now contains anthranilate of potassa and free alkali; neutralize the alkali with sulphuric acid, dissolve out the anthranilate with alcohol, and decompose it with acetic acid, when orange-colored crystals of impure anthranilic acid will be obtained. Purify by uniting it with lime, crystallizing the salt and decomposing it with acetic acid,

when large colorless tabular crystals will be deposited as the solution cools. This is the pure hydrated acid.

Remarks. This acid is fusible and volatile, yielding crystals resembling those of benzoic acid. It dissolves in water, alcohol, and ether, and forms salts with the bases, called anthranilates. By destructive distillation, it yields aniline.

ANTI-ATTRITION. *Prep.* Grind together blacklead with 4 times its weight of lard or tallow. *Use.* To lessen friction in machinery, and to prevent iron rusting. *Remark.* This was once a *patent* article. Camphor is sometimes added, (7 lbs. to the cwt.)

ANTIDOTES. Medicines used to prevent or remove the effects of any poison or disease. Attached to each of the principal poisonous preparations mentioned in this work, the reader will find a notice of the best antidotes and treatment of cases of poisoning therewith.

ANTIHECTIC POWDER, POTERIUS'. *Prep.* Melt equal parts of tin and metallic antimony, powder, mix with six parts of powdered nitre, and deflagrate in a red hot crucible; lastly, powder and wash well with water. *Uses.* Astringent and tonic; formerly used in consumption. *Dose.* 10 to 30 grs. It is a mere mixture of the oxides of antimony and tin.

ANTIHYSTERIC DRAUGHT. (Dr. Josat.) *Prep.* Cyanuret of potassium 0·05 grammes; distilled lettuce water 60 grammes; sirup of orange flowers 20 grammes; mix.

Admin. One or two teaspoonfuls every ten minutes when the fit is expected; during the fit it may be given in larger doses; which, however intense, will be stopped or greatly allayed. Such is the assurance of Dr. Josat, who declares its efficacy to have been indisputably proved, in upward of 55 cases.

ANTIFERMENT. A substance sold in the cider districts, for the purpose of arresting fermentation. *Prep.* I. It generally consists of sulphite of lime in powder, or a mixture of equal parts of the sulphite and powdered mustard.

II. Mix together 14 lbs. of mustard seed with 1 lb. of cloves, and bruise them well without drying.

Use. A portion of either of the above added to cider or perry, tends to allay the fermentation, when it has been renewed. The second may be used for wine and beer as well as cider. *Caution.* In the above the sulph*ite* must be employed, not the sulph*ate*, which is quite a different article. (See Fermentation.)

ANTIMONIC ACID. *Syn.* Peroxide of Antimony. An acid compound formed of antimony and oxygen. It is the metal in its highest state of oxidation.

Prep. I. Digest metallic antimony in strong nitric acid, or dissolve it in nitro-muriatic acid; then evaporate by heat until the excess of acid be expelled, and throw the solution into cold water. The precipitate is the hydrated acid; by exposure to a heat of about 500° or 600° Fahr., the water is driven off, and the anhydrous acid remains behind.

II. Mix powdered metallic antimony with six times its weight of nitre, ignite in a silver crucible, and when cold, wash out the excess of alkali with hot water; the remaining antimoniate of potash, decomposed by muriatic acid, yields an insoluble residue of antimonic acid.

Prop. The hydrated acid (freshly precipitated) reddens litmus, and is insoluble in water, unless soured with tartaric or muriatic acid. When heated nearly to redness, it gives out oxygen and becomes antimonious acid. The hydrated acid is a white powder; the anhydrous acid has a pale yellow color, and is insoluble in water even with the assistance of the acids. With the bases it forms salts called antimoniates. *Uses.* It has been used in medicine, but owing to the high state of oxidation of the metal, appears to be nearly inert. It is said to be diaphoretic in doses of 2 to 10 grs., but it has been given in ½ oz. doses, 2 or 3 times daily, with good effect? (Wilson.) It is now seldom used in medicine. *Tests.* (See Antimony and Antimonious Acid.)

ANTIMONIOUS ACID. *Syn.* Binoxide of Antimony. Deutoxide of Antimony. An acid of antimony, containing 1 eq. less of oxygen than the last, or 2 eq. of antimony, and 4 eq. of oxygen.

Prep. I. Expose the white hydrated antimonic acid to a red heat, when 1 eq. of oxygen will be driven off along with the water, and pure antimonious acid remain.

II. Either the oxide or sulphuret of antimony, exposed to a strong heat, long contained in open vessels, gradually absorbs oxygen, and passes into antimonious acid.

III. The hydrated acid may be prepared by adding an acid to the antimonite of an alkali.

Prop. White, very infusible; insoluble in water, likewise in acids after being heated to redness. It combines with the bases forming salts called antimonites. The hydrated acid reddens litmus and dissolves in the muriatic and tartaric acids. *Use.* It is employed in medicine, and forms the basis of the celebrated nostrum, James's powder, as well as the pulvis antimonialis of the L. Ph. It appears, however, to be very inactive and uncertain in its operation. Dr. Elliotson exhibited the pulvis antimonialis, which contains nearly 40 per cent. of this acid, in doses of upwards of 100 grs., without producing any visible effect. The high state of oxidation in which the antimony exists in this compound, as mentioned in the last article, may account for its inactivity.

Remarks. Neither the salts of this nor the last acid have been applied to any useful purpose. *Tests.* (See Antimony.)

ANTIMONY. *Syn.* Metallic Antimony. Regulus of Antimony. *Hist., &c.* This word is generally applied to a gray metallic ore, which is a *sulphuret* of antimony. The pure metal, formerly called regulus of antimony, is of a whitish color, and semi-crystalline appearance. The derivation of the name is singular: Basil Valentine, a monk who flourished in the 15th century, believing that it fattened pigs, administered some to his brethren, with the charitable intention of giving them a plump appearance, but the experiment was attended with fatal results. Hence it was called "*anti-moine*," "*antimonk*," and gradually, antimony. The sulphuret is even now often given by farriers to horses, to render their coats sleek.

Prep. I. Heat the protoxide of antimony to redness in a crucible, having previously mixed it with an equal weight of cream of tartar; pour the melted metal into conical moulds.

II. Mix the powdered sulphuret of antimony of commerce with ½ its weight of iron filings, and submit it to a strong red heat in a covered crucible.

III. Common sulphuret of antimony 16 oz., cream of tartar 12 oz., nitre 6 oz.; mix, and proceed as above. When cold, separate the scoria. *Remarks.* The first form gives a chemically pure metal. On the large scale, the ore of antimony is reduced in a peculiarly shaped flame furnace, and afterwards melted under coal dust, in crucibles holding 20 to 30 lbs., placed upon a reverberatory hearth. The following formula has been recommended on the large scale.

IV. 100 parts of sulphuret ore, 60 parts of hammerschlag, (oxide of iron from the rolling mills,) 50 parts of common soda, or glauber salts, and 10 parts of charcoal. (Berthier.) *Prod.* From 65 to 70 parts of good metal.

Prop. Antimony is a whitish, brittle, volatile, and inflammable metal, and imparts its brittleness to its alloys.

Uses. It is used in medicine; combined with lead, it forms type metals, and with lead and tin, music plate metal, pewter, &c.

Tests. Sulphureted hydrogen throws down an orange-colored precipitate, soluble in pure potassa, and also in hot muriatic acid; from the latter solution, water throws down a whitish powder. If the sample be in the solid state, powder, boil in muriatic acid, and test as above.

Estim. Strongly acidulate the solution with tartaric acid, then throw down the antimony as a sulphuret by passing sulphureted hydrogen gas through it. After warming the solution and allowing it to cool again, the precipitate may be collected on a filter, dried, and weighed. A small portion must now be digested in strong muriatic acid, which will completely dissolve it if it be the simple sulphuret; in which case the quantity of antimony will be obtained by multiplying the weight of the sulphuret by 5, and dividing the product by 7. Should, however, only part of the precipitate be soluble in strong muriatic acid, a known weight of it must be introduced into a flask, and fuming nitric acid added, drop by drop, with great care, until a considerable quantity has been thus added; hydrochloric acid should now be added, and the mixture digested at a gentle heat, until the whole of the sulphur be dissolved. The solution must next be diluted with water, strongly acidulated with tartaric acid, and chloride of barium added as long as it produces a precipitate. This collected, dried, and weighed, and the weight divided by 3, will give the quantity of sulphur in the sample last operated on, which, by proper allowance and deduction from the weight of the sulphuret first found, will give the quantity of metal as before.

ANTIMONY ASH. *Prep.* Roast the common sulphuret of antimony in an earthen crucible for an hour. *Remarks.* Emetic in small doses, used to make metallic antimony.

ANTIMONY, DIAPHORETIC. *Syn.* Calx of Antimony. Peroxide of Antimony. *Prep.* Mix 1 lb. of powdered sulphuret of antimony with 3 lbs. of powdered nitre, and deflagrate by spoonfuls at a time, in a red hot crucible; collect the calx and powder it.

Remarks. The flowers that collect on the sides of the crucible must be carefully rejected, as they are violently emetic. *Use.* Once much employed in medicine as a gentle diaphoretic and laxative When this article has been well washed in water, it is called washed diaphoretic antimony, washed calx of ditto, &c. The process deprives it of some of its alkali.

ANTIMONY, FLOWERS OF. *Prep.* Throw powdered sulphuret of antimony, by spoonfuls, into an ignited tubulated retort, that has a short and very wide neck, until as many flowers collect in the receiver as are required. *Remarks* An impure oxysulphuret of antimony. Emetic in doses of 1 to 3 grs.

ANTIMONY, FLOWERS OF, (ARGENTINE.) *Syn.* Sesquioxide of Antimony. *Prep.* Keep metallic antimony melted in a vessel, freely exposed to the air, and furnished with a cool place for the flowers to rest upon; collect the flowers as deposited. *Remarks.* These flowers were formerly thought to be the binoxide, but Berzelius has clearly shown them to be the sesquioxide.

ANTIMONY, FULMINATING. *Syn* Fulminating Antimonial Powder. *Prep.* I. Grind well together 100 parts of dried tartar emetic, and 3 parts of lamp-black, or charcoal powder, then take a crucible, capable of holding 3 oz. of water, and having ground its edge smooth, and rubbed the inside with powdered charcoal, ¾ fill it with the above mixture, cover it with a layer of charcoal powder, and lute on the cover. Expose it for 3 hours to strong heat in a reverberatory furnace, and when taken out, let it stand to cool for 6 or 7 hours, before removing its contents, to prevent an explosion. The crucible being now opened, the contents must be hastily transferred without breaking to a wide-mouthed stoppered vial, when, after some time, it will crumble down into a powder of itself. (M. Serullas.)

II. Triturate together, very carefully, 100 parts of antimony, 75 parts of carbureted (roasted to blackness) cream of tartar, and 12 parts of lampblack: preserve it in vials. (Ann. de Chim., Oct. 1822.)

Remarks. When the above processes are properly conducted, the resulting powders fulminate violently on contact with water. It is to the presence of the very inflammable metal potassium that they owe this property. Another compound, made with 60 parts of carbureted cream of tartar, 120 bismuth, and 1 of nitre, treated as above, contains an alloy very rich in potassium. A piece the size of a pea introduced into a mass of gunpowder explodes it on being thrown into water. *Use.* For making some kind of fireworks. It is very probable that this is the preparation used by Capt. Warner.

ANTIMONY, MAGISTERY OF DIAPHORETIC. *Syn.* Materia Perlata. *Prep.* Add oil of vitriol to the water used in washing diaphoretic antimony, until it ceases to produce a precipitate. Wash this well with water.

ANTIMONY, MARTIAL DIAPHORETIC. *Syn.* Anticachecticum Ludovici. *Prep.* Fuse

equal weights of iron filings and sulphuret of antimony in a crucible, cool, powder, and mix with 3 times their weight of nitre, and deflagrate them by spoonfuls in a red hot crucible. Wash the product in water, and collect the brown precipitate. *Use.* Formerly given as a tonic, in doses of 10 to 20 grs.

ANTIMONY, MEDICINAL. *Syn.* MEDICINAL REGULUS OF ANTIMONY. *Prep.* Crude antimony in powder, melted with nearly its own weight of salt, and about ¼ of its weight of potash, or ½ its weight of a mixture of nitre and argol. When cold, separate the ashes from the mass, wash and powder. *Use.* Said to be stronger than crude antimony. Used in some quack medicines.

ANTIMONY, MURIATE OF. *Syn.* BUTTER OF ANTIMONY. CHLORIDE OF DITTO. SESQUICHLORIDE OF DITTO. OIL OF CAUSTIC ANTIMONY. *Prep.* Mix 2 parts of metallic antimony with 5 parts of corrosive sublimate, and distil from a wide-necked retort.

II. Grind together equal parts of common antimony and corrosive sublimate, and proceed as before.

III. Common antimony roasted until gray, or glass of antimony, 9 oz.; powder and mix with common salt 2 lbs.; oil of vitriol 1½ lb.; water 1 lb.; distil. *Prod.* 2½ lbs. of butter of antimony.

IV. Common sulphuret or glass of antimony, as last, 7 lbs.; common salt, 28 lbs.; oil vitriol, 21 lbs.; water, 14 lbs.; distil.

V. Boil 20 parts of powdered common sulphuret of antimony, in 100 parts of muriatic acid to which 1 part of nitric acid has been added. A little pernitrate of iron is used to color it, and it is made up to the sp. gr. of about 1·4. This article is improved if the crude antimony be roasted before dissolving it in the acid.

Prop. When pure, it somewhat resembles butter, melts with a gentle heat, and crystallizes on cooling; it deliquesces into an oily liquid when exposed in a damp place, and this was once the common method of obtaining a cheaper article for sale. It is decomposed by water. *Use.* It is a common caustic with farriers.

Remarks. The first of these processes produces the pure sesquichloride of antimony, the second an article less pure, and the last one the liquid sold as butter of antimony in the shops. The solution of the antimony in the acid is attended with the evolution of a large quantity of sulphureted hydrogen; it should therefore be done under a chimney.

ANTIMONY, SOLUTION OF MURIATE OF. *Syn.* LIQUOR STIBII MURIATICI. (Pharm. Borruss.) *Prep.* Dissolve pure oxide of antimony in pure muriatic acid.

ANTIMONY, OXIDE OF. *Syn.* SESQUIOXIDE OF ANTIMONY. *Prep.* I. (P. E.) Dissolve ℥iv of sulphuret of antimony in fine powder, in 1 pint of muriatic acid by heat, filter and pour the solution into 5 pints of water, collect the precipitate on a calico filter, and wash it well, *first* with cold water, and then with a weak solution of carbonate of soda; and lastly, a second time with cold water, until the latter ceases to affect turmeric paper. Dry with a gentle heat.

II. To the solution of the sulphuret of antimony as prepared above, enough water is added at 167° Fahr. to produce slight turbidness; it is then left to itself until all the sulphureted hydrogen has escaped, when it is again filtered and mixed with 6 times its weight of water. *Prod.* From 4 oz. of the sulphuret,—1¾ oz. pure white oxide of antimony soluble without residue in tartaric acid. (Giesler.)

III. Digest the precipitate obtained by mixing chloride of antimony with cold water, in a weak solution of carbonate of potassa, having first well washed it with cold water; agitate occasionally for some hours, then collect the powder, wash it well and dry it.

IV. Add a solution of carbonate of soda to another of tartar emetic; wash the precipitate well, and dry it.

Remarks. This is a dirty white powder; fusible and volatile; changing into antimonious acid when strongly heated in open vessels. It is a feeble base. *Uses.* To make tartar emetic, and in medicine, as a diaphoretic, in doses of 2 to 10 grs., and an emetic and purgative in larger doses. It has been proposed as a substitute for James's Powder. *Pur. and Tests.* It is completely soluble in hydrochloric acid, and again thrown down as a white powder by cold water; perfectly soluble in a solution of tartaric acid; it is thrown down from its solutions as an orange-red powder by sulphureted hydrogen; it volatilizes by heat.

ANTIMONY, OXYCHLORIDE OF. *Syn.* MERCURIUS VITÆ. POWDER OF ALGAROTH. OXYDUM ANTIMONII NITRO-MURIATICUM, (D. P.) *Prep.* Mix the liquid chloride of antimony with cold water; wash and dry the precipitate. *Prop.* Similar to the oxide. Used to make tartar emetic.

ANTIMONY, PURGING. *Syn.* CATHARTIC ANTIMONY. *Prep.* Digest ½ lb. of glass of antimony in 1½ lb. of oil of vitriol for two days, evaporate to dryness, powder and wash the residuum; dry and melt with 4 oz. of Glauber salts, and 8 oz. of sal enixum; again powder, wash, and dry. *Remarks.* This has been said to be the most certain of all the antimonial purges. *Dose.* 2 to 10 grs Seldom used.

ANTIMONY, SMELTED. *Prep.* Melt crude antimony, and pour it into conical moulds. *Uses, &c.* Diaphoretic and alterative. *Dose.* 10 to 60 grs. Used in rheumatism, scrofula, and skin diseases the refining of gold, &c.; and when reduced to powder. by ladies, to paint their eyelashes black.

ANTISEPTICS Substances that prevent putrefaction. The principal antiseptics are *common salt, saltpetre, spices, sugar, vinegar*, and *creosote*. For antiseptic process, see ANIMAL SUBSTANCES, PUTREFACTION, PROVISIONS, &c.

ANTISEPTIC MEDICINES. Of these the principal ones are *bark, acids, wine, spirits*, and *camphor*.

ANTISPASMODICS. Medicines that allay spasms and other pains. *Bark, opium, camphor, ether, musk, castor, assafœtida, valerian*, and *chalybeates*, are antispasmodics.

ANTISPASMODIC MIXTURE. (DR. COLLIER.) *Prep.* Mixtures of assafœtida and camphor of each ℥iss, tincture of valerian ℥j. Mix. *Dose.* One tablespoonful three or four times daily.

ANXIETY, NERVOUS. This unpleasant state may be removed by keeping the bowels reg-

ular with mild purgatives, taking plenty of exercise in the open air, adopting a light nutritious diet, and seeking pleasant society. A teaspoonful of carbonate of soda or magnesia, or a few drops of laudanum, taken the last thing at night, will generally have the effect of *preventing watchfulness.*

APERIENT. A medicine that gently opens the bowels. Among the best mild aperients may be mentioned small doses of *castor oil, Epsom salts, phosphate of soda,* (*tasteless salt,*) or *seidlitz powder; compound rhubarb pills, compound aloetic pills,* and *pil. rufi.*

APERIENT, DR. COLLIER'S SALINE, (ANTIMONIAL.) *Ing.* Double tartrate of potassa and soda ℥ij, carbonate of soda ʒij, outer yellow peel of the orange (fresh) ʒij, tartar emetic 1 gr., boiling water 1½ pint. *Pro.* Pour the water on the other ingredients, and macerate until cold in a covered vessel. *Dose.* A small tumbler or teacupful, mixed with a tablespoonful of lemon juice, or about a dozen grains of tartaric or citric acid, and drunk while effervescing, forms an agreeable mild aperient.

APIARY. (From *apis,* a bee.) A place where bees are kept.

Establishment of an Apiary. The proper time for this purpose is about February, or the beginning of March, as the stocks have then passed through the winter in safety; the combs are then empty of broods, and light of honey, and may be removed with safety and ease. *Stocks* should be selected by a competent judge, as the weight alone cannot always be relied on; such as weigh 12 lbs. and upwards, the number of bees being also observed, and that they are well combed to near the bottom, may be safely chosen.

As soon as they are brought home they should be set in the *bee-house,* care being taken to keep them dry and from the attacks of vermin. The next day plaster the hive to the bee-board, leaving an entrance the size of the little finger.

If the season has passed, the first and early swarm should be selected, as late ones or casts are not worth keeping, unless two or three of them have been united.

The time for removing stocks is in the evening; the hives should be raised by wedges some hours previous, unless the floor be moveable with the hive, otherwise many bees will remain on the floor at the time of removal, and prove very troublesome. When the floor is moveable, plaster the hive with mortar to the board, and pin a card pierced with holes before the entrance; in this way it will travel any distance in safety.

Swarms should be brought home the same evening that they are purchased; if delayed a day or two, combs will be worked, and subject to be broken in removing.

Management of Bees. The best situation for bees is to the north, with a range of hills wooded on the summit, and toward the base enriched with heather; and southward, gardens where hardy winter-greens have been allowed to flower, as early food for the bees. White mustard should also be sown very early, in patches near the hives; but not nearer than one yard. A few dwarf flowers may come within two feet, but tall ones would assist insects to get up. To the west it would be desirable to have a shrubbery, a wood, a broomy common, or heather moor.

The stations for the hives must be six yards asunder, and never nearer than three yards. The board on which they are placed ought to be of one piece; or if joined, the under side of the joining should be lined with a thinner board, fixed closely with wooden pins. The edges of this rounded standard should project four inches all round from the hive. Place it on three wooden pillars sixteen inches long, ten inches above the ground, but six inches of its length should be firmly thrust into the earth; in all, its length should be sixteen inches. The pillar in front should be an inch shorter than the other two, and the three pillars should be within twelve or fourteen inches of the outer edge of the board, to exclude rats and mice. For the same reason no tall-growing plant, no wall, nor any means for ascent should be within three or four feet of the hive. In fine weather the entrance to the hive must be four inches long, and an inch and a half in depth.

In the beginning of the fine season, when the bees can get food, or have stores remaining, the bee-master has nothing to do but to keep the ground about the hives clear from weeds, and from whatever might enable vermin to climb there. Yet as a thriving stock inclines very soon to swarm, the hives must be frequently looked after from eight in the morning till five in the afternoon. The symptoms are generally thus:—The little city seems crowded with inhabitants. They are continually in motion during the day; and after working-time they make loud noises. The drones may be seen flying about in the heat of the day, and the working bees go with a reeling motion and busy hum. When the bees come regularly out of the hive, let no noise, no interruption incommode them; but if they fly long, as if they were unsettled, some tinkling noise, or the loud report of a gun, will make the fugitives repair to the nearest lodgings. If there is an empty hive, with combs and some honey in it, they will readily go there. If a new hive is used, remember to smooth it well within, and singe off loose straws. Perpendicular sticks should never be employed. Four cross sticks at equal distances will support the combs. Old hives do very well for late swarms, that are not to be preserved through the winter; but box-hives are best for them, as the bees work fastest there. They are not, however, fit for being kept through the cold seasons.

It is to be observed, that great haste in forcing a swarm into the hive may disperse them. Give them time to settle undisturbed, though keep a steady eye on their motions; but whenever they gather into a cluster, lose no time in placing the hive over them. If the swarm rest on any thing that can be brought to the ground, spread a clean linen cloth; lay two sticks on it, two feet asunder; lay the body on which the swarm have fixed, gently on the sticks, covering it with the hive by a motion the least perceptible, and taking care that the edges of the hive rest upon the sticks. Cover hive and all with a cloth, for the sun might allure the bees to rise again. When they have gone into the hive, cover it with its own board, and carry it cautiously to its station. Bees are

apt to leave their hive even after they begin to work, so they must be watched till evening, and throughout the ensuing day. Whenever they are sure to remain, fix the hive to its board with a little lime round the edges; and crown it with green sods, to keep out too great heat or rain.

If a hive divides into two swarms, it is a sign that each swarm has a queen. Put each into old hives or boxes, but they must be kept separate. If a cluster of bees about the size of a small plum are seen together, the queen will generally be found there. Separate them, and with a drinking glass turned down, you may seize the queen. Put her, and a score or two of her subjects, into a box full of holes, large enough to admit air, and yet not to allow the bees to escape. Feed her with honey-combs, and keep her in reserve in case of the death of a queen in one of the hives. When a hive ceases to work, it is a sure sign the queen is no more. Then the bee-master may wait an hour and not see a loaded bee enter the habitation. But if the spare queen be taken late in the evening, (wet her wings to prevent her escape,) and introduced to the desponding society, they will receive her gladly, and begin to work.

If a hive fight among themselves, be assured there are two queens; and they will destroy each other, if one is not taken away.

When bees are to swarm a second or more times they do not come out in clusters; but they make a sound called *bellings*, which may be heard; ceasing for a little, and renewed again and again. If there are different tones, it is certain there are several young queens in the hive. It is only by putting the ear close to it that the sound can be heard distinctly.

To take the honey without destroying the bees. In the dusk of the evening, when the bees are quietly lodged, approach the hive, and turn it gently over. Having steadily placed it in a small pit, previously dug to receive it, with its bottom upwards, cover it with a clean new hive, which has been properly prepared, with a few sticks across the inside of it, and rubbed with aromatic herbs. Having carefully adjusted the mouth of each hive to the other, so that no aperture remains between them, take a small stick, and beat gently round the sides of the lower hive for about ten minutes or a quarter of an hour, in which time the bees will leave their cells in the lower hive, ascend, and adhere to the upper one. Then gently lift the new hive, with all its little tenants, and place it on the stand from which the other hive was taken. This should be done some time in the week preceding Midsummer-day, that the bees may have time, before the summer flowers have faded, to lay in a new stock of honey, which they will not fail to do, for their subsistence through winter.

The color of the honey shows whether it is fine or inferior. If it be wanted to press some in the comb, choose the fairest and those that have not been broken: wrap each comb in white paper, such as lines the blue cover of loaf sugar. Set it edgewise as it stood in the hive, and it may be preserved many months. The combs meant to be drained must be cut in slices. Lay them on a hair-search, supported by a rack over the jar, in which the honey is to remain; for the less it is stirred after draining, it keeps the better. Fill the jar to the brim, as a little scum must be taken off when it has settled. A bladder well washed in lukewarm water, ought to be laid over the double fold of white paper with which it is covered.

To keep hives for winter. They must not be more than three years old, and well stocked with bees. A hive for preserving should weigh from thirty to forty pounds. Place them in October where they are to remain. Stocks of less weight than 21 lbs. in September should never be kept. In most cases light stocks will require feeding, which may be done by inserting little troughs containing a mixture of equal parts of sugar and mild beer, into the hive in the evening, and removing them the next morning. (See also BEES.)

APOPLEXY. A sudden suspension or loss of the powers of sense and motion; the heart continuing to beat and the lungs to act, but generally with difficulty. During the fit the patient frequently lies in a state resembling sleep, or the stupor induced by drunkenness.

Treat. Medical aid should be *immediately* sought, as the delay of only a few minutes may render the skill of the most talented surgeon unavailing. Until the arrival of the latter, the patient should be kept easy and cool, with head and shoulders elevated, the neckcloth removed, and the clothes loosened, to avoid pressure on any portion of the body; the windows should be opened, and crowding round the patient especially avoided, a free exposure to fresh air being desirable. In this state of affairs the practitioner should be waited for. Where medical aid cannot be procured, (as in remote places, &c.,) rather copious bleeding from the arm should be resorted to; cold water should be poured upon the head, and the bowels opened by means of active purgatives: 10 grs. of calomel may be immediately given, and its action promoted by the use of saline purgatives and stimulating clysters. The legs may be placed in pretty warm water, and blisters applied between the shoulders. When these means prove successful, the remainder of the treatment may consist in the administration of mild purgatives and diaphoretics, avoiding stimulating food or drinks, and other exciting causes.

Prev. Apoplexy is frequently preceded by giddiness, pain, and swimming in the head, loss of memory, drowsiness, noises in the ears, specks floating before the eyes, nightmare, laborious respiration, &c. When any of these symptoms occur in a person of apoplectic habit, opening medicines and a light diet should be at once adopted, and wine, beer, and spirits avoided; and if the symptoms increase or continue, bleeding may be had recourse to. If the admonitions of nature were attended to, many cases of apoplexy might be prevented.

Remarks. Short, robust, and plethoric persons, having short, thick necks, are the most liable to apoplexy; in them the fit generally comes on without warning. Persons once attacked with this malady are regarded as especially liable to the same again.

APPENSA. I. Root of vervain hung round the neck by a yard of white satin riband for scrofula; but the usual medicines must be exhibited during the same period.

II. A root of the peony suspended to the neck

in epilepsy; its use to be accompanied with that of the most active cathartics.

III. Magnes arsenicalis, or camphor, hung to the neck so as to reach the pit of the stomach, to guard against contagion.

Remarks. All these probably act by keeping up the courage and spirits of the wearer.

APPETITE. An instinctive desire to perform certain natural functions. In its commoner sense, it is confined to a desire for food.

Remarks. The sensations of hunger and thirst are seated in the stomach, and are necessary to the body in a state of health. They are, however, frequently disordered and altered in various ways, in consequence of diseased action of the stomach and nervous system, or from vicious habits. A healthy appetite for food is usually a most certain indication that nature requires a supply; yet when irregular, it should never be indulged in beyond a moderate extent. In the gratification of the appetite, certain regulations should be observed, and a boundary put to mere animal gratification. By slowly eating and thoroughly masticating or chewing the food, the stomach becomes gradually distended, and the individual feels himself satisfied only after he has received a due proportion thereof, sufficient for the nourishment of his body; but, on the contrary, if the food be swallowed too rapidly, and without proper mastication, it will press heavily and roughly against the sides of the stomach, and induce a sensation of fulness, before a sufficient quantity has been taken to meet the continual demands of life; the consequence will be, that hunger will soon return. Persons who labor or take much exercise have generally a better appetite than those who lead a sedentary occupation; this arises from the functions of the stomach and bowels being promoted through the action of the muscles of the abdomen increasing the healthy peristaltic action of those viscera. When an enormous appetite exists in persons leading a sedentary life, it may fairly be presumed that either the food passes off imperfectly digested, or that the coats of the stomach are in an unhealthy state. More food is required in winter than in summer, in consequence of a greater radiation of the heat of the body, and hence a greater desire for food is usually an accompaniment of that season. In persons who lead a more sedentary life in winter than in summer, the reverse is, however, frequently the case; the want of exercise producing a corresponding loss of appetite.

The various deviations from the healthy standard, or the natural desire for food, constitute *diseased appetite*, among which may be mentioned the following.

APPETITE, CANINE. *Syn.* VORACITY. INSATIABLE HUNGER. BULIMIA. This complaint is generally symptomatic of pregnancy, worms, and diseases of the stomach and other viscera, but sometimes exists as a separate disease. Many persons eat enormously from a mere vicious habit, which is certain to weaken the digestion, and thus induce an increasing desire for food.

Treat. When children display a voracious appetite, worms may be suspected, and vermifuges should be administered, which will generally remove it. In adults, the common cause is imperfect digestion, arising from stomach complaints or an excessive consumption of food, by which the system receives an insufficient quantity of nourishment, and the languor and gnawing pain of disease is mistaken for that of hunger. The best plan in this case is to regulate the diet, to keep the bowels moderately open with gentle laxatives, and to administer tonics, as bark and steel, or bitters, as orange peel and gentian. When *pregnancy* is the cause, a plentiful supply of nutritious food and good malt liquor may be adopted with advantage. When the practice wholly depends on vicious habits of indulgence, small doses of tartar-emetic or ipecacuanha, mixed with the food, will generally effect a cure.

APPETITE, DEPRAVED. *Syn.* PICA. A desire for unnatural food, as dirt, cinders, tallow, chalk, &c. *Treat.* The method detailed at the end of the last article may be followed in this. Emetics and purgatives, with rhubarb, bark, and steel, are the best remedies.

APPETITE, DEFICIENT. A bad appetite generally arises from a disordered stomach, and is best improved by exercise and the occasional use of saline purgatives. Chalybeates and bitters will also prove advantageous. A piece of rhubarb chewed an hour before dinner is employed by some persons to create an appetite; others suck 2 or 3 ginger lozenges, or take a small glass of bitters, for the same purpose. One or two 4-grain compound aloes pills of the London Pharmacopœia, taken in the middle of the morning, have been strongly recommended, under the name of dinner pills. (See also DYSPEPSIA.)

APPETITE, DRAUGHT TO PROMOTE THE. Compound tincture of gentian ½ oz.; sal volatile ½ a teaspoonful; cinnamon water 1 oz.; compound tincture of cardamoms 1 teaspoonful. Mix for a draught to be taken an hour before a meal.

APPETITE, MIXTURE TO RESTORE THE. *Prep.* Gentian root sliced ½ oz.; fresh orange and lemon peel, each 1 oz.; tincture of rhubarb 1 oz.; compound tincture of cardamoms ½ oz.; spirits of red lavender ½ oz.; boiling water 1 pint. *Proc.* Pour the water on the gentian and peels, and macerate for 2 hours; strain, and add the other ingredients; and if it be wanted very clear, it may be filtered through blotting paper; lastly, add 2 oz. of lump sugar. *Dose.* A small wine-glassful early in the morning or shortly before dinner.

APPLE. The apple is a wholesome and pleasant fruit when perfectly ripe, and may be eaten either raw, roasted, or boiled. The more aromatic and flavored varieties are well adapted for dessert fruit, and are especially useful to persons of a full or confined habit of body.

APPLE-FOOL. Put the peeled and cored fruit into a jar, with moist sugar to render it palatable, and a very little cider or perry; place the jar in a saucepan of water over the fire, and continue the heat until the apples become quite soft, then pulp them through a colander, and add a sufficient quantity of milk, a little cream, and sugar to complete the sweetening. Mix well.

APPLES A LA CREMONA. *Prep.* Cut the best cooking apples into small squares, until you have about 1½ lb., strew over them 1 lb. of

good moist sugar and several long strips of lemon-peel, then cover them up close in a bowl. Next day put the apples, &c., piece by piece, into a small stewpan, with 3 or 4 tablespoonfuls of cidor or perry, and simmer gently until they become clear; then take them out, and when cold build a wall round a small dish with the square pieces, place the strips of lemon-peel on the top, and pour the sirup into the middle.

APPLES, DRIED. *Syn.* BAKED APPLES. *Prep.* Place any quantity of apples in a cool oven, 6 or 7 times in succession, flattening them each time by gentle pressure, gradually applied, as soon as they are soft enough to bear it; then take them out, and as soon as cold put them on clean dishes or glass plates. The sour or tart variety of apples is the best for baking.

APPLES AND PEARS, PRESERVATION OF. One of the best ways to preserve valuable fruit of this description, is to wrap each in a piece of clean dry paper, and to fill small wide-mouthed jars or honey-pots therewith, and to pack them in the following manner, in a dry and very cold place, (as a cellar,) but where the frost cannot reach them. The pots, of the shape of fig. 1, are placed in rows one in the other, as in fig. 2, and the space (*a*) between the two pots filled up with plaster of Paris made into a paste with water; the joint is thus rendered air-tight, and the fruit will keep good for a long time. The mouth of the top jar should be covered with a slate.

1.

2.

Remarks. The fruit should not be *too ripe* for the purpose of being preserved; and the later sort is the best. The jars may be taken one at a time from the store-room, as wanted, and the fruit exposed for a week or ten days in a warm dry room before being eaten, which will much improve the flavor. Another plan, which is a modification of the above, is to place alternate layers of bran or clean dry sand and apples, either naked or wrapped in paper, in jars, until they are full, then to shake them well to settle the bran between the fruit, and to add more if required; they are the : packed away as before described.

II. *Fruit is kept in the large way for the London market* by placing in a cool situation, first a layer of straw or paper, then a layer of apples, next a layer of straw, and so on alternately, to the height of 20 to 25 inches, which cannot be well exceeded, as the weight of the superincumbent fruit would be apt to crush or injure the lower layers. This plan is frequently modified by placing alternate layers of fruit and paper in baskets or hampers, and covering them well over before placing them in the fruit-room. The baskets may then be piled one over the other without injury to the fruit.

Remarks. Apples or other fruit intended for preserving in the above way should never be laid in heaps or allowed to touch each other, as they thereby acquire a bad flavor. They should be gathered in dry weather and immediately carried to the fruit-room, when they should be laid, if not *singly*, at least thinly, on the floor or shelves, on paper, and packed away as soon as possible. The use of *brown paper* is inadmissible, as it conveys its peculiar flavor to the fruit. Thick *white brown* paper is the cheapest and the best.

III. (*American method.*) The apples or pears, after being peeled, are cut into eighths, the cores extracted, and then dried in the sun or in a kiln or oven until they are quite hard. *Remarks.* In this way fruit is kept in the United States for two or three years.

For use, wash the fruit in water, then pour boiling water on it; let it stand for a few minutes, and use it as fresh fruit. The water it has soaked in is an excellent substitute for fresh juice.

APPLE SUGAR. *Prep.* Express the juice, and add chalk until the whole of the acid is saturated; pour off the clear liquor; then clarify by boiling in a clean pan with some white of egg; skim off the dirt; and lastly evaporate by a gentle heat to a proper consistence. *Remarks.* 1 cwt. of apples yield about 84 lbs. of juice and 12 lbs. of crude sugar.

APRICOTS, DRIED. *Syn.* CANDIED APRICOTS. *Prep.* Thrust out the stones with a wooden skewer, then pare them and roll them in dry powdered lump sugar; afterwards put them into a cold sirup, made with 2 lbs. of lump sugar to ¾ of a pint of water, and heat them gradually *nearly* to the boiling point, turning them frequently. Then pour them into a deep dish, and next day scald them again, adding as much sugar as will dissolve; again let them rest until the next day, when they must be placed on a hair-sieve to drain and dry.

Remarks. The fruit should not be quite ripe. Sometimes the apricots are cut into halves or quarters before preserving, and at other times pickled with the skins on; in the latter case they are gathered sooner, and infused in cold water with some vine leaves; next taken out and gently immersed in fresh water until they turn yellow, and then rubbed with a flannel and some salt to remove the down; they are then again soaked in the pan with the vine leaves, until they turn greenish. The best are now selected, rubbed dry, the stones extracted, and boiled in sirup as above described.

AQUETTA. The poison prepared by the once notorious woman named Toffana Tophana, appears to have been alkarsine, or some preparation of the kadodule series, to which article the reader is referred. The emperor Charles VI. declared to his physician Garelli, that it was arsenic dissolved in aqua cymbelaria.

ARABESQUE. The ornamental designs of this kind, so much employed to beautify leather and fancy cloth binding, are produced by the pressure of hot plates or rollers, having the design sunk into them. (See BOOKBINDING.)

ARABINE. *Syn.* SOLUBLE GUM. *Prep.* Dissolve gum arabic in water; filter, and add alcohol to throw down the arabine; filter and dry the residuum by a gentle heat. *Prop.* Similar to pure gum arabic; over the finer sorts it possesses little or no advantage.

ARBUTUS SUGAR. *Prep.* From the fruit of the strawberry, in the same way as apple sugar. Strawberries are said to yield one-fifth of their weight of sugar, and the rape, or pressings, yield by fermentation and distillation a very pleasant spirit.

ARCANUM BECCHINUM. A solution of livers of sulphur and sugar in water. (Willis.)

ARCANUM CORALLINUM. Red oxide of mercury digested in potash water, and spirits burned on it. *Remarks.* Formerly used to excite salivation and as an escharotic.

ARCANUM DUPLICUM CATHOLICUM. An amulet composed of the roots of plantain and colchicum, recommended by Wedel against contagion. A relic of superstition.

ARCHIL. *Syn.* ORCHIL. TURNSOLE. LITMUS. CUDBEAR. PERSIO. A beautiful violet-red or blue color, prepared from several species of lichens, (the rocellus, parellus, &c.) In Great Britain it is principally prepared from the lecanora tartarea and parmelia omphilodes. Archil is met with in three states—a violet-red liquid paste—in blue lumps—and in powder.

Uses, &c. It is largely employed to dye blues, violets, &c., mixed with other colors, to which it imparts a beautiful bloom. It is generally used as a finishing bath, by passing the fabric, already dyed of the same color, through archil mixed with hot water. Its beauty, however, is deceptive, and soon decays. *Solvents.* Water, urine, ammoniacal and alkaline lyes, acidulated water. *Alkalis* turn it *blue, acids red;* hence its value as a test for these articles in chemistry. Spirit stained with archil is sometimes used to fill the tubes of thermometers, but the color soon fades. An aqueous infusion of archil stains marble of a beautiful violet color of considerable permanence. (Fay.) In the state of powder it is called cudbear, under which form, when used with skill, it possesses greater permanency, and dyes all shades, from pink and crimson to blue. The word archil, as commonly applied, means the liquid archil, or violet color, sold for staining wood, dyeing, &c. Lump archil, or dyer's archil, a similar colored substance, under the form of a paste or lumps. Turnsole or litmus is archil prepared of a bluish color, and made up into small lumps, and cudbear is archil in the state of powder, which has undergone some trifling preparation for the dyer. The names are, however, frequently used indiscriminately.

ARCHIL, TO DYE WITH. *Proc.* Diffuse the archil or cudbear in warm water, then raise it to nearly the boiling point, and pass the cloth, previously prepared by rinsing in cold water, through the dye until the proper shade is produced.

Remarks. This plan is principally employed to bloom or finish off goods dyed of a permanent color, as before alluded to. Pearlash, or milk of lime, added to the bath, deepens the shade; acids redden it. *A beautiful crimson red* is obtained, by first passing the stuff through a mordant of tin and tartar, and then through a bath of archil mixed with a little solution of tin. By proper management of this dye, lilachs, violets, mallows, rosemary flowers, soupes au vin, agates, and other shades may be produced, on silk or cloth, either alone, or in conjunction with other dyes to modify it. ½ lb. of archil or cudbear will dye 1 to 2 lbs. of cloth.

ARCHIL, FACTITIOUS. A factitious coloring matter, resembling archil, is prepared by fermenting together a mixture of rotten onions with an equal weight of pearlash, for a few days, and then adding ½ of the weight of the pearlash in sugar of lead. The particulars of the process essential to its success are, however, kept a secret.

ARCHIL, INFUSION OF. *Syn.* INFUSION OF LITMUS. *Prep.* Digest 1 oz. of powdered litmus in 1 pint of hot water, and filter. *Remarks.* It will not keep without the addition of spirit. Used for testing. (See the TINCTURE.)

ARCHIL, LIQUID. *Syn.* COMMON ARCHIL, (of the shops.) *Prep.* The archil lichen, well bruised between stones, is moistened with a crude ammoniacal liquor, or urine, mixed with a little quicklime; in a few days it acquires a purplish red color, and is then steeped in urine until all the color is extracted. *Use.* As a dye, especially for staining wood, and tinging silk stockings, &c.

Remarks. When the process is conducted with free access of air, and in rooms heated by steam, (stove rooms,) the color turns more on the violet, and the product is called *red* archil; but when the manufacture is carried on in close vessels, the product is bluish, and hence called blue archil. In this way various shades of color are produced.

ARCHIL, LUMP. *Syn.* LITMUS. TURNSOLE. *Prep.* The archil plant, ground to powder, is moistened with urine, or bone spirit, and allowed to lie together for a few days, to ferment; a small proportion of chalk or gypsum is now added, and the whole is made up into small squares, (lump archil,) or preserved in the state of paste.

Remarks. When the ground lichen is mixed with about half its weight of pearlash before fermenting, and afterwards made with a small quantity of lime, it becomes quite blue, and is then called *litmus* or *turnsole.*

ARCHIL PAPER. *Syn.* LITMUS PAPER. I. (*Blue.*) *Prep.* Stain thin unglazed writing-paper with infusion of litmus; dry, and keep it from the light. *Use.* As a test for acids, which turn it red. *Remarks.* It should be of a *blue* color. Should the infusion of litmus turn a little on the violet, add a minute quantity of alkali (which will turn it blue) before wetting the paper.

II. (*Red.*) Add 2 or 3 drops of acetic acid to the infusion of litmus, or enough to turn it red; then stain the paper, as above. *Use.* As a test turned blue by alkalis.

Remarks. A convenient extemporaneous method of preparing this paper, is to take a strip of the blue litmus paper, and hold it for an instant over a bottle containing muriatic acid, which will turn it red. In this state it is very sensitive to alkalis. A good method of keeping these papers for use, is to cut them into strips about ½ an inch wide and 3 inches long, and to tie them up in bundles, or to keep them in a box of a similar size to the paper. They are then always ready for use, as well as excluded from the light.

ARCHIL, POWDERED. *Syn.* CUDBEAR. DYER'S ARCHIL. *Prep.* The bruised archil lichen is sprinkled with bone spirit and urine, and allowed to ferment for a few days in the open air, as before described, when it is dried and ground to a fine powder. *Use.* As a dye.

ARCHIL, TINCTURE OF. *Syn.* TINCTURE OF LITMUS. I. (*Blue.*) *Ing.* Litmus, in powder, 1 oz.; water and rectified spirit, of each, ½ pint. *Proc.* Digest for a week. *Use.* As a test. It turns red with acids.

II. (*Red.*) To the above add acetic acid, just

sufficient to tinge it red. *Use.* As a test; turned blue by alkalis.

Remarks. A very slight trace of either acids or alkalis may be detected in mineral waters, or saline solutions, by means of either the infusion or the tincture of litmus, or litmus paper. The latter is, however, the more convenient, and is that generally used.

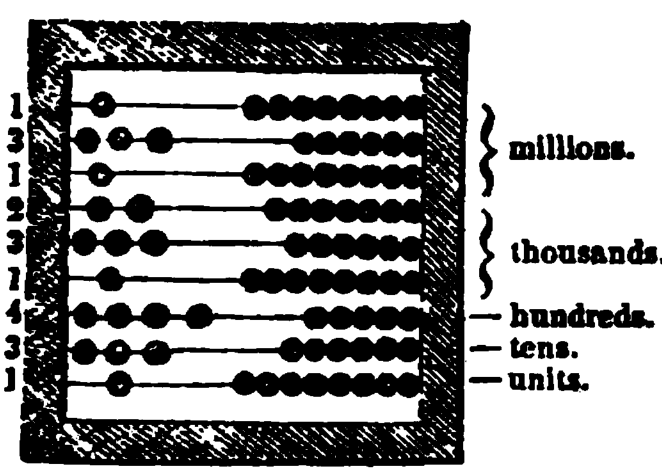
ARCÆUS, BALSAM OF. Mutton suet 4 parts; hogs' lard 2 parts; turpentine and rosin, of each, 3 parts. *Proc.* Melt, add 4 parts of hot water, and beat together until cold. *Remarks.* Once a noted ointment for sores and bruises.

ARICINA. *Syn.* Aricine. Cusconine. Cusco-cinchonia. An alkaline principle, discovered by Pelletier and Coriol, in the bark of the arica, or cusco-cinchona.

Prep. Boil the bark in water acidulated with sulphuric acid; repeat the process a second and third time; concentrate the mixed liquors, and precipitate with ammonia. Collect the powder on a filter, and purify by repeated resolutions and crystallizations from hot alcohol.

Remarks. It forms salts with the acids. It is supposed to be the teroxide of the base, of which quina is thought to be the binoxide and cinchona the monoxide.

ARITHMETER. *Syn.* Abacus. An instrument frequently employed in schools to teach young children the rudiments of arithmetic. Its construction is similar to the abacus of the Greek. The lines represent the nine digits, and progress from units upwards, as will be easily understood from the annexed figure, which has the number



131,231,431 on it, according to the common system of notation. Sometimes a small ball is suspended over the lines, which in that case adds *five* to the line below, and thus reduces the number of balls on each wire from 9 to 5.

ARNICINE. A resinous substance extracted by alcohol from the root and flowers of the mountain arnica. (Pfaff.)

ARRACK. A spirituous liquor, procured by distillation from palm-wine, or a fermented infusion of rice. It is imported from the East Indies, and much used to make punch. When sliced pine apples are placed in arrack, and the spirit kept for some time, it acquires a most delicious flavor, and is thought to be unrivalled for making nectarial punch.

ARRACK, FACTITIOUS. *Syn.* Mock Arrack. Vauxhall Nectar. *Prep.* Dissolve 23 grs. of flowers of benzoin (benzoic acid) in 1 quart of good pale Jamaica rum. *Sold for arrack.*

ARROW ROOT. A very pure and nutritious species of starch, prepared in the West Indies from the root of the maranta arundinacea.

Pur. The mass of what is sold for arrow root, in the shops, consists either wholly or in part of the fecula or farina, obtained from potatoes, and commonly called potato starch. This article is known in the trade as "*British arrow root,*" or simply "*arrow root,*" whereas, the genuine kind is always described as "*Bermuda,*" "*St. Vincent,*" "*St. Kitts,*" or at least as "*West Indian arrow root.*" The mere addition of an adjective is no proof of quality, and no sample should be bought without a proper examination. Arrow root is imported in tin canisters or cases, and in boxes and casks, but the former is most esteemed.

Tests, &c. Genuine arrow root is odorless and tasteless, and produces a sort of crackling noise when pressed or rubbed, and emits no peculiar odor when mixed with muriatic acid. Stirred up in a mortar with double its weight of a mixture of equal parts of aquafortis and water, it does not become gelatinous and adhesive in less than 15 minutes. (Dr. Scharling.)

ARROW ROOT, EAST INDIAN. *Source.* The roots of the curcuma angustifolia. *Char.* A white powder, somewhat resembling bicarbonate of soda or rochella salts. It does not crepitate between the fingers like West Indian arrow root.

ARROW ROOT, BRAZILIAN. *Syn.* Tapioca Meal. *Source.* The cassava plant. *Char.* Partially soluble in cold water; appearance inferior to W. I. arrow root; grains, mullar-shaped, when viewed by the microscope.

ARROW ROOT, ENGLISH. *Syn.* Farina. Potato Starch. *Source.* The esculent potato.

Char. I. When mixed with muriatic acid, a smell resembling fresh beans or rushes may be perceived. (Ann. Chem.)

II. One drachm of potato starch rubbed in a mortar, with a mixture of one drachm of aquafortis, previously diluted with 1 drachm of water, forms rapidly a very stiff and tenacious jelly. 5§ of potato starch, mixed with West Indian arrow root, may be detected in this way. (Scharling.)

ARROW ROOT, PORTLAND. *Source* The tubers of the arum maculatum, or wake-robin. *Char.* It resembles the Brazilian arrow root, mentioned above.

Remarks. By attention to the characteristics of each of the above varieties, the purity of any sample may be easily ascertained. The grains of each variety have a different appearance when viewed by the microscope, but when the sophistication takes place before grinding, the original form of the grains of each is lost, and this method of examination is then useless. The reader is referred, for further information on this subject, to Dr. Pereira's excellent work on Materia Medica, where he will find the subject fully explained and illustrated by engravings, from the pencil of the doctor's talented lady, representing the appearance of the magnified grains.

ARSENIATES. Salts formed of the arsenic acid and the bases. They are all poisonous. Most of the metallic arseniates may be made by adding a soluble salt of the metal to a solution of the acid, when the arseniate is precipitated.

ARSENIATE OF AMMONIA AND SODA, DOUBLE. *Prep.* Mix the separate solutions of the arseniate of soda and ammonia, evaporate and crystallize. *Poisonous.*

Remarks. In a similar way are made the double arseniates of soda and potassa, and of ammonia and potassa.

ARSENIATE OF BARYTA. *Prep.* Add a solution of chloride of barium to another of arseniate of potassa or soda; collect the precipitate and wash it well. *Remarks.* By dissolving this salt in a solution of arsenic acid and crystallizing, a biarseniate of baryta is obtained.

ARSENIATE OF POTASSA. *Prep.* Saturate a solution of the acid with potassa. Uncrystallizable.

ARSENIATE OF POTASSA, (SUPER- OR BI-.) *Syn.* ARSENIATED KALI. MACQUEER'S NEUTRAL ARSENICAL SALT. *Prep.* Heat together equal weights of nitre and arsenious acid; dissolve the melted mass in water, evaporate and crystallize.

Prop., Uses, &c. This salt is obtained in large crystals. It is tonic. *Dose* $\frac{1}{16}$ to $\frac{1}{4}$ of gr.; used in making cobalt blue.

Remarks. By a similar process to the above, the arseniates of lime and magnesia may be made. This salt (potassa) is made on a very extensive scale in Saxony.

ARSENIATE OF SODA. Saturate a solution of arsenic acid with another of carbonate of soda; evaporate and crystallize.

ARSENIATE OF SODA, (SUPER OR BI-SALT. *Prep.* Heat together in a crucible or bolthead, a mixture of 9 oz. of white arsenic with 1 lb. of dry nitrate of soda, until all the nitric acid be expelled. *Dose.* $\frac{1}{8}$ to $\frac{1}{6}$ gr.

ARSENIC. *Syn.* METALLIC ARSENIC. REGULUS OF ARSENIC. BLACK ARSENIC. A brittle, inflammable, volatile, and combustible metal, the base of white arsenic or arsenious acid.

Prep. I. Mix white arsenic in powder with twice its weight of black flux, and expose the mixture to a red heat, in a Hessian crucible, over which is luted an empty crucible to receive the metal. The upper one must be kept cool.

II. Mix white arsenic with twice its weight of soft soap, and fuse it in a crucible, with a very quick fire; pour the melted metal into inverted hot iron cones.

Remarks. The first is the more convenient process. *Caut.* Too much care cannot be taken to avoid inhaling the fumes; the process should be conducted only where there is a strong current of air to carry them off. On the large scale it is procured by distilling white arsenic with charcoal and iron, or lime. *Use.* To whiten copper, and in medicine.

ARSENIC, BROMIDE OF. *Syn.* SESQUIBROMIDE OF ARSENIC. *Prep.* Add dry arsenic in powder, cautiously, and in small quantities at a time, to bromine, as long as light continues to be emitted, then distil into a cool receiver. (Serullas.) *Prop.* Solid below 68°, boils at 428°. When liquid it is yellowish. *Poisonous.*

ARSENIC, PROTOCHLORIDE OF. *Prep.* Mix in a tubulated retort 1 part of arsenious acid, and 10 parts of strong sulphuric acid; heat to 212°, and throw in gradually small quantities of sea salt. Collect the chloride in a well-cooled receiver. (Dumas.) *Remarks.* The pure protochloride swims on a little hydrated portion when the process has been too long continued. The latter may be rendered anhydrous by distillation from strong sulphuric acid.

ARSENIC, SESQUICHLORIDE. *Syn.* CHLORIDE OF ARSENIC. BUTTER OF ARSENIC, FUMING LIQUOR OF DITTO. *Prep.* I. Distil together 6 parts of corrosive sublimate and 1 of arsenic. II. Boil muriatic acid, mixed with a little nitric acid, upon arsenic for some time, then concentrate and distil, (if required.)

Remarks. All the above are poisonous, corrosive, and volatile.

ARSENIC, IODIDE OF. *Syn.* PERIODIDE OF ARSENIC. *Prep.* Gently heat together in a tube or flask, 1 part of metallic arsenic in fine powder, with 6¼ parts of iodine, then sublime the iodide to separate the excess of arsenic. A sand-bath or the heat of a spirit-lamp should be employed for this purpose. *Prop.* An orange-red solid, volatile and soluble in water. *Dose.* $\frac{1}{8}$ to $\frac{1}{4}$ of gr. in lepra, lupus, psoriasis, impetigo, &c.

ARSENIC, OINTMENT OF IODIDE OF. (BIETT.) *Prep.* Mix well together 3 grs. of iodide of arsenic and 1 oz. of lard. *Use.* In corroding tubercular diseases.

ARSENIC, RED SULPHURET OF. *Syn.* PROTOSULPHURET OF ARSENIC. RED ARSENIC. REALGAR. This substance is found ready formed in nature, but it may also be produced by art.

Prep. Powdered white arsenic 2 parts, flowers of sulphur 1 part. *Proc.* Heat them together in a crucible, until in a state of perfect fusion.

Prop. Transparent ruby red-colored mass. *Very poisonous. Uses.* As a pigment and in fireworks. Not used in medicine. Its color is improved by sublimation in close vessels.

ARSENIC, YELLOW SULPHURET OF. *Syn.* SESQUISULPHURET OF ARSENIC. YELLOW ARSENIC. SULPHOARSENIOUS ACID. ORPIMENT. KING'S YELLOW. This sulphuret, like the last, is found ready formed in nature, and was once called auripigmentum, from its fine color.

Prep. I. Mix together equal parts of sulphur and arsenious acid, and sublime in a close vessel.

II. Transmit a current of sulphureted hydrogen gas through a solution of arsenious acid; collect the precipitate and well wash it in cold water.

Prop. Yellow crystalline lump, or fine golden yellow powder; very soluble in the pure alkalis.

Uses. As a dye, a pigment, in fireworks, and in some depilatories. Silk, woollen, or cotton goods, soaked in a solution of this substance in ammonia, and then suspended in a warm apartment, are permanently dyed of a beautiful yellow color. The native sulphurets (both red and yellow) are much less soluble than those prepared artificially, and are consequently less poisonous. The native varieties possess the finest color, and are hence preferred by artists. If sulphureted hydrogen be transmitted through a solution of arsenic acid, a persulphuret is formed which much resembles orpiment.

ARSENICAL CAUSTIC. (JUSTAMOND'S.) *Prep.* Melt together 2 parts of white arsenic and 1 part of antimony; when cold reduce the mass to a fine powder.

Remarks. A poisonous and dangerous escharotic, employed by M. Justamond, mixed with powdered opium, in cancer. It is seldom used in England.

ARSENICAL SOLUTION *Syn.* (Dr. DE-

VERGIE'S MINERAL SOLUTION.) *Prep.* Arsenious acid (crystallized) 0·10 centigramme; carbonate of potassa 0·10 centigramme; distilled water 500 grammes; compound tincture of melissa 0·50 centigramme; tincture of cochineal to a deep rose color. *Proc.* Dissolve the acid and potassa in the water, (hot,) and when cold add the rest.

Remarks. Each gramme is equal to $\frac{1}{5000}$ of arsenious acid, or $\frac{1}{36}$ of the strength of Fowler's solution. *Used* in similar cases to the solution of arsenite of potassa of the L. Ph., over which it is said to possess the advantages of greater convenience and safety in dispensing.

ARSENIC ACID. An acid formed by the combination of metallic arsenic with oxygen. *Hist.* The combinations of this acid were noticed by Macqueer, but we are indebted to Scheele for the subsequent discovery of the acid.

Prep. Pour 6 parts of strong nitric acid on 1 part of white arsenic in a glass vessel, and distil until the solution acquires the consistence of a sirup, then transfer it into a platina crucible, and expose it for some time to a faint dull red heat, to expel the nitric acid. *Remark.* The addition of a little muriatic acid facilitates the process. (Liebig.)

II. Submit arsenious acid to the action of aqueous chlorine.

Prop. Sour, reddens litmus, dissolves in 6 times its weight of cold water, (twice its weight, Lagrange,) and less of boiling, and forms salts with the bases, called arseniates. By careful evaporation it may be obtained under the form of small grains, but as usually met with has the consistence of sirup. It is deliquescent.

Use. It has not been employed in medicine, or the arts, but indirectly some of its combinations have been used in dyeing. It is a *more* violent poison than even the arsenious acid. (Brodie.)

Tests. Sulphureted hydrogen gives a yellow precipitate; nitrate of silver added to the solution of an arseniate, gives a precipitate of a brick red color; nitrate of lead gives a *white* one, and the salts of copper a bluish colored one. Pure lump sugar dissolved in an aqueous solution of arsenic acid, becomes in a few hours of a reddish color, and afterwards of a magnificent purple. (Ure.) This acid, whether free or combined, is reduced to the metallic state, and evolves a garlic odor when heated with charcoal. Wohler recommends the addition of sulphurous acid to the suspected liquor, and to boil it for a short time, when the arsenic acid will be reduced to arsenious acid, in which state it will be more susceptible of tests. See the next article.

ARSENIOUS ACID. *Syn.* WHITE ARSENIC. OXIDE OF ARSENIC. ARSENIC BLANC. ACIDE ARSENIEUX. (*Fr.*) ARSENICHSTE SAURE, GIFT MEHL. (*Ger.*) ACIDUM ARSENIOSUM. (P. L.) *Hist., Des., &c.* This substance, like the preceding, is a compound of metallic arsenic and oxygen, and is a powerful poison; in fact, one of the most virulent of the class to which it belongs. It is commonly known by the simple title of "*arsenic*," a term derived from the Greek, ἀρσενικόν, an epithet once applied to those natural substances which possess strongly poisonous and acrimonious properties; as orpiment was the usual form under which arsenic occurred, it consequently received the name, and hence this word has gradually been altered to its present application. (Paris.) Scheele first proved the white arsenic of the shops to consist of a metal and oxygen, but Fourcroy gave it the name of arsenious acid.

Source. The white arsenic of commerce is principally imported from Germany, where it is obtained in the process of roasting the arsenureted cobalt ores for making zaffre. At Altenburg it is procured from arsenical iron pyrites, and at Riechenstein from the sesquiarseniate of iron. About 600 to 800 tons are also annually collected in Cornwall, being a secondary product of the process of roasting the gray copper ores and white mundic. The crude article obtained in this way has to be purified by sublimation in suitable iron vessels, before it is fit for sale. It then forms a semi-transparent vitreous cake, which gradually becomes opaque, and of a snowy whiteness by exposure to the air, and *sometimes* falls into a pulverulent state on the surface. The powdered white arsenic of the shops is generally adulterated with plaster of Paris, white sand, or ground bone ashes, and is totally unfit for the purposes of chemistry or the manufacturer. To avoid this fraud, the best way is to purchase it in the lump, which will generally be found sufficiently pure. When wanted *very pure*, it may be resublimed in glass.

Prop. Volatilizes at 380° Fahr. Vapors smell of garlic; sp. gr. 3·7. Its taste is usually thought to be acrid, but this is not the case. It may be deliberately tasted without exciting more than a very faint impression of sweetness, and perhaps slight acidity. (Turner.) I can say from painful experience that such is the case. Hence its dangerous character as a poison. 100 parts of boiling water dissolve 8 parts of arsenious acid, (Bucholz and Klaproth;) but on cooling to 60° only 3 parts remain in solution. The opaque variety is the more soluble. (Guibourt.)

Uses. Extensively employed in the arts, and in medicine. In small therapeutical doses it is a valuable remedy in intermittent fevers, chronic skin diseases, (especially lepra and psoriasis,) and in some nervous diseases, (as neuralgia, epilepsy, chorea, tetanus, &c.) It is the active ingredient in the "*tasteless ague drop*," and the Tanjore pills, long celebrated in India for the cure of the bite of the cobra di capello, and other venomous serpents, as well as hydrophobia. It has been given in syphilis, chronic rheumatism, typhus, and several other diseases, with more or less advantage. Externally it has been employed in the form of powder, lotion, and ointment for the cure of cancer. Its use, whether internal or external, is always attended with danger, and should never be adopted without proper advice. It even proves destructive to vegetable life, (Jäger, Marcet, Macaire.) *Dose.* In substance, made into pills with crumb of bread and lump sugar, $\frac{1}{16}$th to $\frac{1}{8}$th of a grain, or in solution, (the liq. of arsenite of potassa, P. L.) 4 to 5 drops, 2 or 3 times daily, gradually and cautiously increased to 10 or 15 drops.

Pur. 1. It should wholly volatilize by heat. 2. 5 grs. boiled in 1 oz. of water should dissolve without leaving any residue. 3. Mixed with half its weight of black flux, and heated, it should sublime with the production of a garlic odor, and leave an ash behind, perfectly soluble in distilled water.

ARSENIOUS ACID, TESTING FOR. *Memo.* For the sake of brevity and convenience of reference, I shall describe the usual tests for arsenic, in alphabetical order, appending such remarks to each, as will render their application quite simple, even to persons but partially conversant with chemical manipulations.

I. *Ammoniacal acetate of copper* in a state of weak solution, gives a fine grass-green and very characteristic precipitate of arsenite of copper, or Scheele's green. This precipitate, well washed, and acted on by sulphureted hydrogen water, turns brownish-red; prussiate of potash turns it blood-red, and nitrate of silver yellow.

Susc. $\frac{1}{110000}$. (Ure.)

II. *Ammoniacal nitrate of silver. Syn. Hume's test.* A solution of this test, added to an aqueous solution of arsenious acid, gives a yellow precipitate of arsenite of silver. This precipitate is soluble in liquid ammonia, nitric acid, and in a solution of nitrate of ammonia.

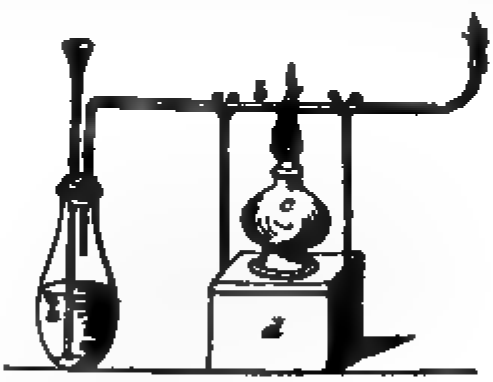
Susc. $\frac{1}{150000}$. (Devergie.)

Remarks. This test, when properly prepared, yields a yellow precipitate with no known substance save arsenious acid. It is usually said to be inapplicable to solutions containing sulphate or muriate of soda, or chlorine; but Dr. Ure declares that these substances do not interfere with the test if it be used in the following manner:—Dip a small glass rod into liquid ammonia, and then plunge it into the fluid under examination; dip another glass rod into a solution of pure nitrate of silver, and plunge this also into the sample, when either a fine yellow cloud will be formed, or at first merely a white curdy precipitate. After a second or third immersion of the nitrate rod, a central yellow spot will be perceived, surrounded with the white chloride of silver; and after another immersion the yellow cloud on the surface will become very evident. Another modification of this process is, to drop a little of the suspected fluid on white writing-paper, and to draw several times over it a stick of lunar caustic; if arsenic be present it will leave streaks that will assume a bright yellow color when brushed over with liquid ammonia; if the contrary be the case they will gradually fade and turn black. (Dr. Paris.)

III. *Ammoniacal sulphate of copper.* A dilute solution of this salt, added to another containing arsenious acid, gives a green precipitate of arsenite of copper.

Susc. $\frac{1}{5000}$. (Devergie.)

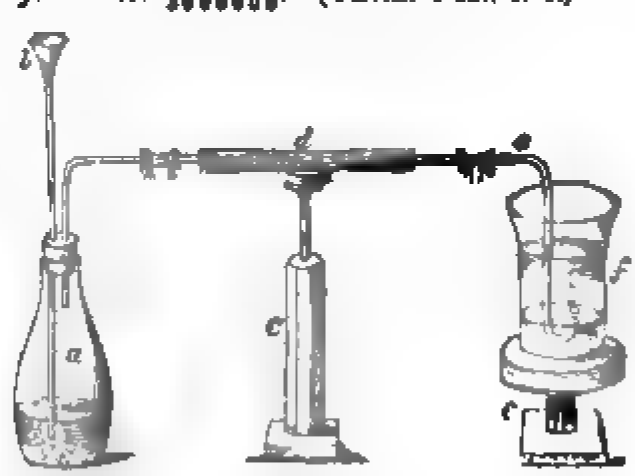
IV. *Ellis's Test.* This consists in forming arseniureted hydrogen gas in a Marsh's apparatus, or even in a common flask, and passing it through a horizontal tube containing slips of copper-leaf or riband, and having the one end drawn to a capillary size, at which the gas may be inflamed and tested. (See fig. below.) This is not, however, the object of the test, as will be presently seen. A small spirit-lamp must be placed under that part of the tube containing the copper, so as to render it warm, when, if arsenic be abundant in the gas, the copper will almost instantly become frosted over with a coating of metallic arsenic. After continuing the heat for a few minutes the lamp may be withdrawn. The copper on being removed from the tube will present a beautiful silvery surface, and may then be submitted to further examination. (See *Reinsch's Test*, p. 77.) The slips of copper are directed to be prepared for this purpose by heating them in a clear fire to a dull red, and then throwing them suddenly into cold water; when wiped dry they are ready for being placed in the horizontal tube for testing.



a, Flask containing the suspected fluid, dilute sulphuric acid, and zinc.
b, Portion of tube holding slips of copper.
c, Spirit-lamp.
d, Support.

Remarks. Mr. Robert Ellis has since found that the oxide of copper may be employed in the same way, and possesses some advantages over the metal. *Susc.* About $\frac{1}{500000}$.

V. *Lassaigne's Test.* (*Adopted by the French Academy.*) This consists in passing the arseniureted hydrogen, generated in a flask or Marsh's apparatus, through a solution of nitrate of silver. (See eng.) Black flocculi of metallic silver are deposited, and arsenious acid remains in solution mixed with nitric acid. A little dilute hydrochloric acid must now be added to precipitate any remaining nitrate of silver, when the liquid, after filtration, may be tested for arsenic in the usual way. *Susc.* $\frac{1}{2000000}$. (Chem. Gaz., I. 6.)



a, Bottle containing dilute sulphuric acid, zinc, and suspected fluid.
b, Funnel for supplying the bottle with acid.
c c, Supports.
d, Tube filled with asbestos.
e, Bent tube to convey the liberated gas.
f, Glass vessel containing a solution of nitrate of silver.

VI. *Lime Test.* Lime water occasions a white precipitate of arsenite of lime in a solution of arsenious acid, soluble in most acids, and in an excess of the arsenious solution. *Susc.* $\frac{1}{4000}$. (Devergie.) It is inapplicable when acids, oxalates, tartrates, or carbonates are present.

VII. *Marsh's Test. Syn. Arseniureted hydrogen test.* This test consists in the production and subsequent decomposition of arseniureted hydrogen. The principle of its action depends on

the property possessed by nascent hydrogen, of taking the metal from a solution of arsenious acid. The process is as follows: Some of the suspected liquid is mixed with dilute sulphuric acid and poured upon some pieces of zinc previously placed in the apparatus; hydrogen gas is immediately evolved, and if arsenic be present unites with it, forming arseniureted hydrogen gas, which may be recognised as follows:—

1. It possesses a garlic-like smell.

2. It burns with a bluish-white flame, and emits a whitish smoke.

3. When a piece of window-glass, or a white porcelain plate or saucer, is held a short distance *above* the flame, arsenious acid, under the form of a fine pulverulent film, is deposited thereon.

4. When the plate is held *in* the flame, a blackish deposite of metallic arsenic acid is obtained.

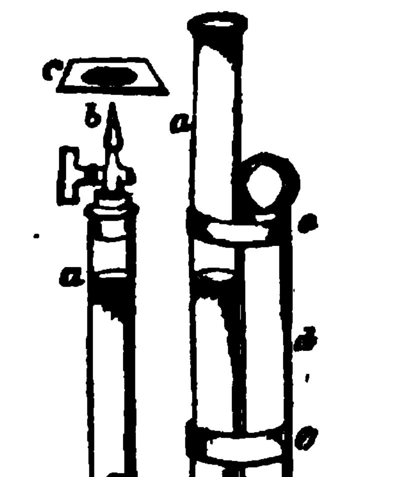
₄ Both these deposites may be obtained simultaneously by holding nearly vertically over the flame a glass tube 8 or 10 inches long, and $\frac{3}{8}$ths of an inch in diameter.

5. A solution of arsenious acid may be obtained by letting the flame play upon 3 or 4 drops of water, placed on the under side of the piece of glass or china, to which the liquid tests may be then applied. Another plan is to apply drops of the liquid tests to the plate as above, and to let the flame play on them successively.

6. The true arsenical spot is soluble in nitric acid, and gives with nitrate of silver a dull red precipitate; and when heated is turned reddish-brown by the action of sulphureted hydrogen.

7. When a tube through which the gas is made to pass is raised to a dull red heat at a certain part by means of a spirit lamp, a crust of metallic arsenic is deposited beyond the flame, on the cooler portion of the tube. The glass of which the tube is made should be of the most infusible kind. The mode of conducting this experiment is represented in the eng. at p. 76, omitting the copper wire.

Remarks. Care should be taken not to light the jet of gas before all the air is expelled from the apparatus, as without this precaution an explosion may take place. The following figure represents



a a, Bent glass tube, containing dilute sulphuric acid, zinc, and suspected fluid.
b, Stopcock and jet.
c d, Support.
e e, Bands to keep the tube upright.
f, Plate of glass to receive the stain.

the usual form of Mr. Marsh's apparatus, as well as the mode of its application in analysis; but a simple wide-mouthed bottle, furnished with a tube and cock, will answer quite as well or better, as the fluid is less liable to froth than in a narrow tube. Even a common medicine-vial, furnished with a tobacco-pipe for a burner, may be used when no more convenient apparatus is at hand.

Some objections have been raised to this mode of testing, from the great frothing which occurs in organic mixtures, and from antimony and imperfectly charred organic matter also forming crusts somewhat resembling those produced by arsenic. But this objection is invalid, because there are easy means of discriminating between true arsenical spots or deposites and false ones. (See the *Reduction Test*, p. 78.) Another objection is, that both zinc and sulphuric acid sometimes contain arsenic; but this is frivolous, as it only becomes necessary to observe that the substances employed be perfectly pure, which may be proved by testing the hydrogen evolved from the apparatus, before adding the liquid for examination.

Susc. $\frac{1}{1000000}$. (Commissioners of the French Academy;) $\frac{1}{5000000}$. (Mohr.;) weak traces at $\frac{3}{50000000}$. (Ann. der Chem. und Pharm.;) the $\frac{1}{150}$ of a grain. (Dr. Thompson.) It may be observed that the 7th, and 3d, or 4th method of using Marsh's apparatus, may be employed simultaneously; the former possesses the advantage of not requiring constant attention. Lassaigne's and Ellis's tests are modifications of Marsh's.

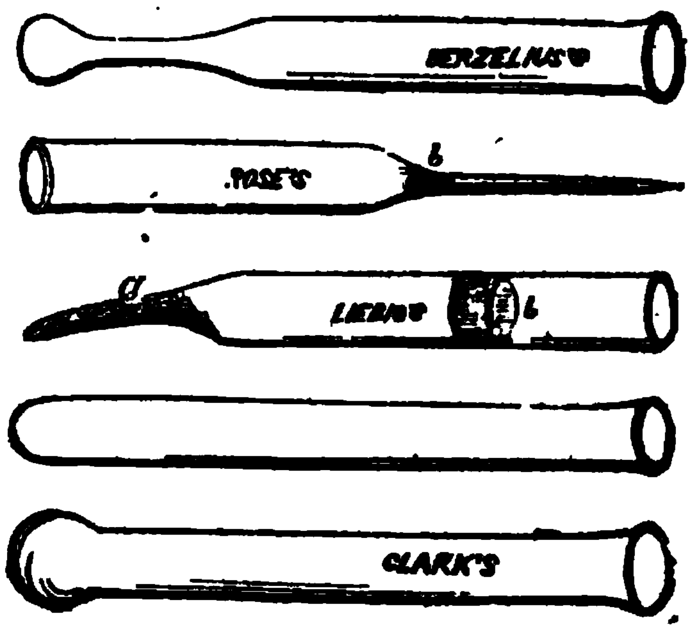
VIII. *Morton's Test.* This consists in immersing in the suspected fluid two platina plates, connected with the poles of a good galvanic battery. The hydrogen liberated at the negative electrode must be collected and examined in the same way as described in the last article. *Remarks.* The advantage of this apparatus is, that it obviates the use of zinc and sulphuric acid, and thus prevents the introduction of arsenic by either of those substances. This advantage is, however, rather *apparent* than *real*, as, with proper care, such need never be the case. *Susc.* $\frac{1}{10000}$. (Morton.)

IX. *Rensch's Test.* *Syn.* *Cupro-arsenical test.* If arsenic is contained in any acid, as, for instance, in phosphoric, sulphuric, acetic acid, &c., and this be boiled with metallic copper, the latter will remain perfectly bright; an aqueous solution of arsenious acid ($As^3 O^3$) likewise does not readily act on copper; if, however, a few drops of concentrated muriatic acid be allowed to run over the surface of the sheet of copper, the liquid being still hot, the copper will be instantly covered with the characteristic iron-gray film of arsenic.

A solution, diluted to 100,000 times, was prepared from another solution of arsenious acid, diluted to $\frac{1}{1000}$; these were mixed, with the utmost precision, with equal parts of concentrated and perfectly pure muriatic acid and distilled water, and different test liquids made with the former, until diluted to $\frac{1}{1000000}$ of its contents. By diluting with 500,000 parts of water, containing, therefore, $\frac{1}{1000000}$ of a grain of arsenic, the copper plate, after the liquor previously boiled had been allowed to stand for half an hour, was for the greater part covered with an extremely thin but

perceptible film of arsenic. As a controlling experiment, a perfectly similar plate was treated with dilute muriatic acid alone; this remained, however, quite unchanged; but it must be observed, that in the case of the copper remaining for several hours in the liquor under the influence of the atmosphere, it becomes covered with a black hue, perhaps an undissolved chloride of copper; this, however, can never cause misconception, since, if arsenic be really contained in the liquor, it will be completely precipitated after the lapse of half an hour, during which space of time metallic copper preserves its lustre in the acid liquor. In masticated food, taken from the contents of the stomach and bowels, arsenic may be as easily detected; they have only to be digested with dilute muriatic acid, and treated with a plate of copper. In order to detect the arsenic by another process, the copper plate must be rinsed with water, carefully dried over a flame, and then placed in a tube 15 inches long, and drawn out to a point at one extremity; a small bent tube, provided at the end with a pierced cork, being hermetically adapted thereto. The place where the copper plate lies must then be heated by the spirit-lamp, when the arsenious acid will sublime in small but perceptibly glittering crystals. If the point be then closed by fusion, the arsenious acid may be examined as such, or it may be dissolved in muriatic acid, and tested with nitrate of silver and sulphureted hydrogen, or in Marsh's apparatus. If it be intended to obtain metallic arsenic, and not arsenious acid, the small tube must be connected with a hydrogen apparatus, and heated. The arsenic will then deposite in its metallic form on any cold object. (Sächsisches Gew. Bl.)

Remarks. The suspected liquor should be kept perfectly acidulous during the whole period of the ebullition; "f℥ij of muriatic acid, to ℥viij of the liquid, are generally sufficient, but if the organic matter be an animal texture in a state of decay," a much larger quantity will be required. (Christison.) Copper leaf cut into small strips is the most convenient form of using that metal. When the quantity of arsenic in the suspected fluid is supposed to be small, nearly half an hour should elapse before the copper should be removed. (Christison.) By means of this test, Dr. Christison discovered arsenic in the stomach 4 months after interment. *Succ.* $\frac{1}{1000000}$. (Rensch.)



a, The arsenical mixture.
b, Arsenical ring.

X. *Reduction Test.* If arsenious acid be well mixed with an equal weight of newly-burnt charcoal, or half its weight of black flux, and the mixture be placed at the bottom of a small glass tube, and heated in the flame of a spirit-lamp or candle, metallic arsenic will sublime, and on reaching the cooler portion of the tube, again condense, in the form of a metallic crust or ring. Any common test-tube, of small diameter, may be employed for this purpose, but the reduction-tube of Berzelius is perhaps the most convenient. Care must be taken, whatever shaped tube may be used, to avoid soiling its sides in the operation of inserting the mixture; as, unless the tube be quite clear and dry, the experiment will not succeed. The preceding figures represent the kind of tubes generally used in this method of testing.

The metallic ring, or crust, is proved to be arsenical,—1, by the brilliancy of its outer surface often resembling a polished steel mirror.

2. The crystalline and grayish-white appearance of its inner surface.

3. Its volatility when heated, shown by its escaping from the hot portion of the tube and resting on the cooler part, further on.

4. Its conversion into minute octohedral crystals of arsenious acid, when repeatedly chased up and down the tube, by the cautious application of the flame of a spirit-lamp, first to one part, and then to another. This is best effected by holding that part of the tube to which the arsenic adheres, about $\frac{1}{4}$ of an inch above the flame, and in such a way that the metal may be slowly sublimed. The character of these crystals, with respect to volatility, lustre, transparency, and form, is so exceedingly well marked, that a practised eye may safely identify them; though their weight should not exceed the $\frac{1}{100}$ part of a grain. (Liebig and Gregory.) The form of the crystals is very evident with a microscope of 4 powers, (200, Wackenroder.) The oxide of antimony never forms octohedrons, but only prisms. (Wackenroder.) The tube is of course broken for this purpose.

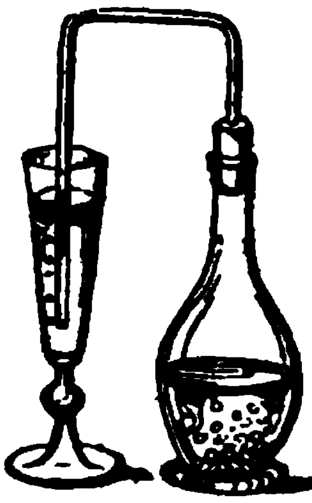
5. The film being converted into arsenious acid as in the last case, may be dissolved in hot distilled water, and tested by any of the usual chemical reagents.

Remarks. The above characteristics will fully show the nature of the film deposited in the reduction-tube. In operating in this way it is always necessary to heat the upper portion of the mixture *first*, and then to expose the bulb or bottom of the tube to the full flame. Any substance containing arsenic may be tested in this way, but if it be a sulphuret, the black flux must be employed, as charcoal alone is insufficient. This test is usually regarded as *decisive*, as we here actually obtain the arsenic in a *solid form*, which may be recognised by the *most unequivocal characters*.

XI. *Sulphureted Hydrogen.* This substance, passed through a solution of arsenious acid, immediately changes it to a yellow color; a turbidness shortly ensues, and a bright yellow precipitate of sesquisulphuret of arsenic or orpiment subsides after heating the liquid, and may be collected on a filter. It is necessary to acidulate the fluid with acetic or hydrochloric acid before applying the test, unless it be already very sour, when it should be first neutralized by an alkali, and then acidulated.

The transmission of the gas should be continued for at least half an hour. The precipitate is known to contain arsenic: 1, From its yellow color; 2, its solubility in liquid ammonia forming a colorless solution; and, 3, by yielding metallic arsenic when mixed with the black flux and submitted to the reduction test.

Remarks. When the sulphuret is very small in quantity, it is better to wash it in a little water, and to dissolve it in liquid ammonia, which may be then driven off in a watch-glass or capsule, after which it may be tested as before. (Devergie.) The engraving represents the mode of executing this test.



Mode of passing sulphureted hydrogen through an arsenical solution.

XII. *Voltaic Test.* The voltaic battery, made to act by two wires on a little arsenious solution, placed on a piece of window glass, developes metallic arsenic at the negative pole, and if the wire be formed of copper, it will become whitened and polished like silver, in consequence of the formation of a tombac alloy.

XIII. *Wollaston's Method* was to concentrate, by heat, in a capsule, a little of the suspected liquid, having previously filtered it if necessary, then to place it in the middle of a bit of window glass, and to draw lines with the fluid in different directions, so as to form a starlike figure. To one of these a particle of weak solution of ammoniacal nitrate of silver was added; to another ammoniacal acetate of copper; to a third the deuto-acetate of iron; to a fourth ammonio-acetate of cobalt; sulphureted hydrogen to a fifth, and lime-water to a sixth; a drop of sirup of violets to a seventh, and the two wires of a galvanic battery to the opposite edges of the whole. Thus with one drop of solution many exact experiments may be made. (Ure.)

General Remarks. *Detection of arsenic in organic mixtures, &c.* Most of the previous tests are only applicable, *with any degree of certainty*, to pure solutions of arsenious acid, or to those that are but *slightly* colored or contaminated with organic matter. The tests depending on the extrication of arseniureted hydrogen are *partial* exceptions to this rule; but even in them, if the suspected liquid be not *nearly limpid*, so much frothing will ensue as to render the process impracticable. In this respect Rensch's test, perhaps, possesses the advantage over the rest, as it may at once be applied to mixtures containing organic matter, without the latter undergoing any previous preparation. The reduction test is only applicable to solid arsenious acid, or to some of the compounds of arsenic which are obtained by means of the other tests. It has long been an object with chemists to remove organic matter from solutions, so as to render them sufficiently clear, light colored, and limpid, to permit of the action of reagents. Various means have been proposed for this purpose, some of which I shall notice below. Suppose a case of poisoning, the proceeding should be as follows:—The stomach being laid open, an examination should be made for any particles of powder which it may contain in an undissolved state; if any can be found they must be collected and tried by the reduction test as before described. Should no solid particles be discovered, the stomach should be cut into small pieces, and with its previous contents be boiled in a glass vessel with distilled water for half an hour, a little potassa or ammonia being added. The liquid may now be filtered, first through muslin and then through paper, and again boiled with a little acetic acid, after which it must be filtered a second time. In this state the liquid is usually clear enough to be tested with the ammonio-nitrate of silver, when, if this test act freely, the process of testing with other reagents may be proceeded with; but if, on the contrary, the indication be feeble, the liquor should be gently evaporated to dryness, and redissolved by boiling in repeated portions of distilled water, when, after being once more filtered, it will generally be sufficiently limpid for the perfect application of the tests. (Christison, Devergie.)

It has been recommended to add to the organic matter contained in a porcelain capsule, one-sixth of its weight of strong, *pure* sulphuric acid, and to heat the mixture until vapors of the acid begin to appear, constantly stirring with a glass rod during the whole time; the heat is to be continued until the charcoal thus formed becomes friable, and almost dry, when it must be cooled a little, and strong nitric or nitro-muriatic acid added by means of a pipette; the evaporation must then be continued to dryness. The residuum boiled with distilled water, and the solution filtered, will be ready for testing. (Danger and Flandin.)

Another plan is to boil the suspected fluid containing organic matter, with *pure* diluted sulphuric acid, until it becomes limpid, and then to filter, when the usual tests may be applied. (Fownes.) When there is much gelatine in the liquid it may be got rid of by adding an infusion of nut-galls, which will precipitate it. (Fownes.)

The last plan I shall mention is that of evaporating the suspected liquid to dryness, and then submitting it to the reduction test.

The following tables, taken from the "London Dispensatory," showing the reaction of several reagents on various organic solutions containing poison, will, in many cases, save the trouble of preparing the fluid previously to testing; or at least they offer a ready means of confirming the truth of any more exact method of analysis.

Comparative Table of the Precipitates obtained from Solutions of Arsenious Acid, of Bichloride of Mercury, of Potassio-Tartrate of Antimony, and of Chloride of Barium, with different Tests.—By Dr. A. T. Thomson.

TEST I.—WATER SATURATED WITH SULPHURETED HYDROGEN GAS.

Solvents.	Precipitates from Solutions of Arsenious Acid.	Precipitates from Solutions of Corrosive Sublimate.	Precipitates from Solutions of Tartar Emetic.	Precipitates from Solutions of Chloride of Barium.
Water ...	Bright lemon yellow, deepened by the addition of a few drops of strong acetic acid.*	Yellow at the instant of its formation, but soon becoming blackish.—On shaking the tube it changes to a dirty white.	Orange, curdy, partly suspended, partly thrown down. Ultimately bright orange.‡	Heavy, and of a dirty dark brown color.
Broth	Scarcely any at first, but on adding a few drops of strong acetic acid, a pale yellow.	Whitish yellow at first, quickly changing to mixed clots of yellow, black and white.	Pale orange at first, soon changing to a deeper bright orange.	Dirty pale brown, heavy.
Milk	Little change; but on the addition of a drop of strong acetic acid, a straw-colored precipitate.	Light ochre, requiring for its formation a large quantity of the test.	Golden yellow, with a shade of orange.	Dirty nankeen, with a shade of brown.
Tea	At first very pale yellow; after some time, a pale greenish yellow. The precipitate was curdy.†	Brownish white and yellow, mixed.	Deep orange, curdy, slowly formed: the supernatant fluid yellow.	Dirty light brown, deepening as it fell.
Madeira Wine	Turbid, pale yellow, the color of the wine destroyed.	Muddy, gradually displaying small floating black flocculi.	Pale orange, long suspended.	The chloride mixed with white wine is milky. Not tested.
Port Wine	Turbid, pale yellow; the precipitate slowly formed.	Nearly as in the white wine, like clouds through the purple of the wine.	Dark, dirty, orange brown.	Pale brown, heavy.
Coffee ...	A deep golden yellow.	Brownish black.	Deep orange-brown.	Not tested.
Gruel	Pale yellow, suspended.	Light brown, slowly formed.	Pale orange.	Not tested.

II.—SOLUTION OF SULPHURET OF POTASSIUM.

Solvents.	Arsenious Acid.	Corrosive Sublimate.	Tartar Emetic.	Chloride of Barium.
Water....	White, with a faint tint of sulphur-yellow, when a large quantity of the test was used.§	Black, mottled with yellow.	Bright orange.	Deep olive-green.
Broth	Pale, but bright, sulphur-yellow.	Clotted, heavy, black, mottled with gray.	Dull orange, heavy.	Pale brown, partly suspended.
Milk	Bright golden-yellow.	Black, clotted.	Orange.	Brown, greenish when the mixture was shaken.
Tea	A beautiful yellow.	Brownish-black.	Reddish orange, flocculent.	Not tried.
Coffee ...	A deep golden-yellow.‖	Nearly black.	Deep brownish-orange.	Not tried.
Madeira Wine	Sulphur-yellow.	Dirty white, or slate color.	Beautiful bright orange.	Vide 1st Table.
Port Wine	Fawn color.	Slate color, with violet supernatant fluid.¶	Dark brown, with a tinge of orange.	Violet, heavy.
Gruel	Bright queen's yellow.	Black dense clots.**	Orange clotted.	Dusky yellowish-green.

* This precipitate, dried upon a filter, and heated with some caustic potassa in a slender test tube, is decomposed in a few seconds, forming a sulphuret of potassium, while the arsenic is volatilized in its metallic form, and adheres to the sides of the tube. (Orfila.)

† All substances containing tannic acid in solution greatly impair the solvent influence of fluids on arsenious acid.

‡ Dr. Pereira states, that, when the solution of the tartar emetic is very dilute, and the sulphureted hydrogen gas passed through it *only for a few seconds*, the precipitate is of a lemon yellow, closely resembling that produced by arsenious acid. (Med. Gaz., April, 1836.)

§ This sulphuret, added to a solution of the phosphates, throws down a greenish-yellow precipitate, the supernatant fluid being yellow and turbid.

‖ Lime water, also, added to coffee containing arsenious acid, throws down a yellow precipitate; although it precipitates the watery solution of arsenious acid white. (Orfila.)

¶ Corrosive sublimate cannot be exhibited in port wine with an intention to commit murder, (except by a self-murderer,) as it changes the color of the wine to pale violet.

** All the precipitates by the sulphuret, when dried, and heated in a tube with iron filings, afford metallic mercury, which forms globules on the sides of the tube.

III.—SOLUTION OF AMMONIACO-SULPHATE OF COPPER.

Solvents.	Precipitates from Solutions of Arsenious Acid.	Precipitates from Solutions of Corrosive Sublimate.	Precipitates from Solutions of Tartar Emetic.	Precipitates from Solutions of Chloride of Barium.
Water....	Beautiful grass-green. It completely disappeared on the addition of a few drops of strong acetic acid.*	White, thick, and heavy.	Pale whitish-blue, very little thrown down.	Copious whitish-blue.
Broth	Beautiful pale green, suspended.†	White, curdy, partly suspended, partly thrown down.	Pale whitish-blue, with a tint of green.	Opaque, glaucous.
Milk	Pale grayish-green.	Bluish-white, curdy.	Whitish-blue.	Curdy white, with a tinge of blue.
Tea	Obscure olive, but scarcely a precipitate.	Dirty yellowish white, curdy.	Muddy, pale bluish-green.	Grayish, heavy, supernatant fluid, yellowish-green.
Coffee....	Dark grass-green.‡	Dirty white.	Dirty bluish-green.	Not tried.
Madeira Wine	Grayish, with a slight tinge of green.	Heavy clotted white, with a tint of green.	Æruginous blue.	Vide 1st Table.
Port Wine	Clotted, heavy, dark greenish-gray.	Heavy, clotted, bluish-gray.	Heavy, dirty slate-blue.	Dirty violaceous-gray.
Gruel	Beautiful grass-green.	Pale bluish-white.	Pale bluish-green.	Pale bluish-green.

IV.—SOLUTION OF AMMONIACO-NITRATE OF SILVER.

Water....	Copious bright sulphur-yellow.§	Dull yellowish white, clotted, changing to dirty-white.	Pale brown.	White, heavy; soon blackening.
Broth	White, (owing to the chloride of sodium,) but yellow when treated with nitric acid.	White, copious.	Brownish, mixed with much muriate of silver.	White, dense, curdy.
Milk	White, with a tint of yellow.	Dirty-white.	Very pale, scarcely visible brown.	Not tried.
Tea......	Yellowish white, which soon blackens.	Dirty-white.	Dirty-brown.	Not tried.
Coffee....	Yellow, remaining unchanged.	White, changing to black.	Not tried.	Not tried.
Madeira Wine	Pale sulphur-yellow.	Dirty-white, changing to black.	White.	Vide 1st Table.
Port Wine	White, becoming brown on exposure to the light.	Idem.	Dirty-white.	Heavy, dirty-white.
Gruel	Yellowish.	Dense, dirty-white clots.	Not tried.	Dense, clotted-white.

Caution. The result of no *single* test should be depended on. Those most to be relied on are the *Reduction test*, *Rensch's test*, and with *proper precautions* those depending on the liberation of *arseniureted hydrogen;* also among the liquid tests, the *ammoniacal acetate and sulphate of copper* and *nitrate of silver.* Otto has lately shown that when a poisonous mass of white of egg and potatoes is boiled with a lye of potassa and afterwards acidulated with muriatic acid, no precipitate is produced by sulphureted hydrogen. This results from the action of potassa on proteine bodies forming a sulphuret of potassium, the sulphur of which being liberated by the acid, throws down the arsenic, which is then removed by filtration. Hence it would appear a bad plan to boil such substances with potassa, as recommended by Christison and Devergie.

ARSENIC, ANTIDOTES TO. The hydrated sesquioxide of iron, in the gelatinous state, appears to be the only substance yet discovered worthy of being considered as an antidote to arsenic. It should be given in doses of a tablespoonful every ten minutes. Lime-water and chalk and

* This test is capable of detecting arsenious acid in a solution containing $\frac{1}{110000}$ of its weight. (Orfila.)

† It has been suggested that onions, boiled in broth, or eaten so as to impregnate with their qualities the contents of the stomach, might produce the same effects on ammoniaco-sulphate of copper, as if arsenious acid were present; but although the fluid is tinged a green color, yet no precipitate forms.

‡ Dr. Porter, of South Carolina, says, that sulphate of copper with ammonia produces the same colored precipitate in coffee which contains no arsenious acid. (American Journal of Science, vol. iii. p. 354.)

§ A similar precipitate is formed by nitrate of silver, in a solution of any of the phosphates, and with chromate of potassa; but the fact of the precipitate being occasioned by arsenious acid is easily ascertained by testing a fresh portion of the solution with lime-water. If it contain arsenious acid, a copious white precipitate will be thrown down; if a phosphate only, there is scarcely any change, or at the most a translucent flocculent precipitate, which remains long suspended. A method of employing this test was suggested by Dr. Paris: namely, to put upon a piece of clean white paper a broad streak of the suspected fluid, and then run lightly over it a stick of lunar caustic; or the streak may be brushed lightly over with liquid ammonia, immediately after the application of the caustic; if arsenious acid be present, a bright queen's yellow is instantly produced, which remains permanent for nearly an hour; but when the lunar caustic produces a bright yellow before the ammonia is applied, we may suspect the presence of some phosphate.

water have also been recommended. Opium, camphor, and ether, may be employed as after remedies, to recruit the nervous system.

Remarks. The first endeavor, in cases of poisoning by arsenic, should be to remove, if possible, the poison from the stomach; for this purpose strong emetics or the stomach-pump should be had recourse to, after which the hydrated sesquioxide of iron may be administered.

ARSENITES. Salts formed of the previous acid (arsenious) and the bases. The alkaline arsenites may be prepared by saturating a solution of the acid, with another of the base, and most of the insoluble arsenites may be made by adding a soluble salt of the metal to a solution of the arsenite of potassa or ammonia.

ARSENIURETED HYDROGEN. A compound of arsenic and hydrogen, discovered by Scheele.

Prep. Melt metallic arsenic with an equal weight of grain zinc, reduce the alloy to coarse powder, place it in a gas bottle, and pour over it strong muriatic acid. (Soubeiran.) It must be collected in the pneumatic trough.

Prop. Inflammable, extinguishes combustion, and destroys life. At a red heat it deposites its arsenic in the metallic state.

ARTICHOKE. This esculent resembles asparagus in its general properties, but it is said to be more nutritious and diuretic. It is dressed in several ways according to the fancy of the cook. See Asafœtida, p. 83.

ASAFŒTIDA CLYSTER. *Prep.* Asafœtida ½ gramme; yelk of 1 egg; water ½ pint. *Proc.* Dissolve. *Use.* This quantity is sufficient for 10 or 12 clysters for children under 1 year; 5 or 6 for those under 3 years; and 2 or 3 for those under 7. Two clysters are prescribed daily in hooping-cough.

Remark. M. Reiken has found this more successful in removing hooping-cough than any other remedy. To ensure success, it should not be administered until the feverish symptoms have passed. M. Reiken sometimes uses an ointment of asafœtida, as well as the clyster.

ASARABACCA SNUFF. *Syn.* Cephalic Snuff. *Prep.* Asarabacca leaves and Lundyfoot snuff, of each 1 oz.; lavender flowers, 1 drachm; essence of bergamotte and oil of cloves, of each 2 drops. *Proc.* Grind the lavender with the snuff and leaves to a fine powder, then add the perfume.

Remarks. This is a great improvement on the old form with herbs. It is an excellent errhine, and is much recommended in headaches, dimness of sight, &c.

ASARINE. A substance resembling camphor, obtained from the root of the Asarum Europæum, (Asarabacca,) by distillation along with water.

ASBOLINE. A substance found by Braconnot in soot, and on which he thinks the anthelmintic virtue of the latter depends. Berzelius regards it as impure acid pyretine.

ASCARIDES. Small thread worms that produce a disagreeable irritation near the extremity of the anus. They are best removed by mild purgatives and the use of a clyster of aloes.

ASCARIDES, ELECTUARY FOR. *Ing* Flowers of sulphur, 4 oz.; powdered jalap, 1 oz. powdered bark, 1 oz.; sirup of buckthorn, q. s *Proc.* Make them into an electuary. *Dose.* Two or three teaspoonfuls every morning.

ASH-BALLS. The ashes of various plants, especially ferns, damped and made into balls. *Use.* As a substitute for soap in washing, and to clean painting.

ASPARAGIN. *Syn.* Asparamide. Althæine Agedoile. A substance found in the potato, marshmallow, liquorice, asparagus, and some other vegetables.

Prep. Boil the expressed juice of the asparagus, filter, and evaporate.

II. Macerate the bruised root of the marshmallow with milk of lime; filter, precipitate with carbonate of ammonia, and evaporate.

Prop. In its purest state it forms large prismatic crystals, soluble in water and proof spirit. Alkalis and acids, with the aid of heat, convert it into aspartic acid.

ASPARAGUS. *Qual., &c.* A very nutritious article of food, possessing slightly diuretic properties, and little disposition to induce flatulence. Asparagus is cooked by boiling, which is done as quickly as possible, without breaking the heads, and is served with melted butter. The head, or upper part, is that which is eaten. Sometimes the lower or white end is removed before boiling. Many nice little side-dishes are made with asparagus; among which the following may be classed:—Cut off the top of a French roll and take away all the crumb, then fry it brown in butter, and fill it with a hot mixture of cream and yelk of egg, previously stirred together over the fire until thickened, and then beat up with the boiled tops of asparagus, and a little salt and nutmeg. Place on the top of the roll that was cut off, and over all stick in a few of the greenest heads of asparagus. This is called "asparagus forced."

ASPARAGUS, CULTIVATION OF. Choose that situation which is the longest exposed to the sun during the heat of the day. Dig a pit 5 feet deep, and sift the mould through a searce, having about 6 holes to the inch; then fill up the bed with the following layers: 1,—6 inches of good dung; 2,—6 inches of turf; 3,—6 inches of dung; 4,—6 inches of sifted earth. Repeat the layers in the same order a second time. Then fill up the last foot with a mixture of equal parts of sifted earth and dung. Now divide the ground into beds, 5 feet wide, by paths made of turf, laid down 18 inches wide and 9 inches deep. The plants must be set in March, 15 inches asunder, placing the bud or top of the root about 1½ inches beneath the surface, and spreading the roots out as much as possible. Mark the place where each plant is set, by placing a small piece of stick in the spot. As soon as the bed begins to sink, a few spadefuls of fine sand may be thrown over it, especially on the spots where the plants are set. Should some of the plants die, their places may be supplied by others, set later in the season. The plants should be 2 years old when transplanted, and in 3 years may be cut for the table.

Remarks. A bed of this kind will last 30 years or longer. The young plants are raised from seed, set two together, about 1 inch deep and 9 inches apart, in beds of good earth, removing the weakest of the two plants in the ensuing spring. A little good dung may be scattered over the beds in

autumn. The male plants alone should be selected for transplanting. During winter, asparagus may be raised by the use of tan in hotbeds.

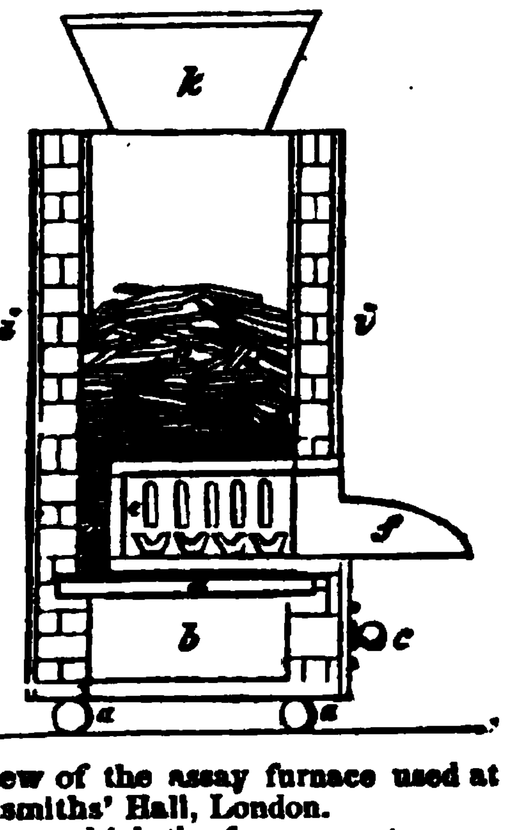
ASPHALTUM, PREPARED. *Syn.* Liquid Asphaltum. *Prep.* I. Melt Scio turpentine 2 oz.; then add powdered asphaltum 1 oz. When mixed, remove the vessel from the fire, cool a little, and add oil of turpentine until it be reduced to a proper consistence.

II. (Wilson's.) Melt 1 oz. of asphaltum; then add 2 oz. of balsam of copaiba. Remove it from the fire, and thin with turpentine.

Remarks. The turpentine must be heated before adding it to the other ingredients, as if cold, they will set before it can be mixed in. *Use.* As a black japan or varnish. An excellent glazing color.

ASPHALTUM, FACTITIOUS. A substance under this name, and which is also often sold for genuine asphaltum, is made from the bottoms of Barbadoes tar, by heating them until quite hard. Color and hardness inferior to asphaltum.

ASSAY, (ASSAYING.) *Syn.* Coupellation, (*Fr.*) Atreiben auf der Capelle, (*Ger.*) The method of determining the quantity of pure gold and silver in the alloys of these metals. This art requires great skill and experience in its performance; and from the costliness of the precious metals, and their general employment in the manufacture of coin, plate, jewellery, &c., is of the utmost importance. At the Royal Mint of England there are two assay-masters—the master's assayer and the king's assayer. The business of the former is to receive and examine the gold and silver ingots brought for coinage, and of the latter to examine the melted bars previously to their being coined into money. When the money is coined, it is "*pixed*" before being sent from the Mint. This consists in making an assay of one piece out of each "*journeyweight*" of coin, to ascertain if it be of the proper standard. The king's assayer thus becomes responsible for the purity of all the gold and silver coin issued from the Mint. The following is a brief notice of the art of assaying.



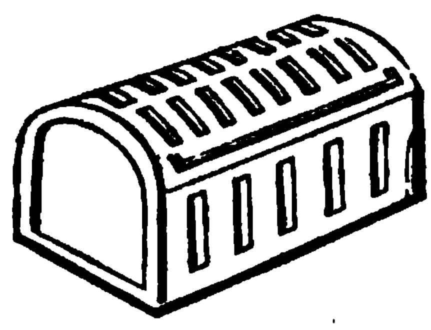
Sectional view of the assay furnace used at the Royal Mint and Goldsmiths' Hall, London.
a a, Rollers on which the furnace rests.
b, Ash-pit. c, One of the ash-pit dampers.
d, Grate supporting the muffle-plate.
e, Muffle containing the cupels.
f, The mouth-plate for the ignited charcoal.
h, Interior of furnace containing charcoal.
i i, Walls of the furnace.
k, Moveable chimney for regulating draught.

Operation of Assaying. *Materials, apparatus, &c.—The furnace.* Before an assay can be made, it is necessary to be provided with a suitable furnace, muffle, and cupel. The *furnace* used for assaying at the Royal Mint and Goldsmiths' Hall, London, has the following proportions, and is represented above.

Dimensions. Total height 2½ feet; from the bottom to the grate, 6 inches; the grate, muffle-plate, and bed of loam that covers it, 3 inches; the space between the grate and the bottom of the funnel or chimney, 21½ inches; funnel, 6 inches. A furnace of any other shape and size may be employed, provided it will afford a sufficient heat, and allow the introduction of the muffle.

The muffle is a pot of the shape of fig. 1, made of clay, and furnished with an opening to admit the introduction of the cupels, and inspection of the process. It is placed on the muffle-plate, (see preceding figure,) by which it is introduced into the furnace.

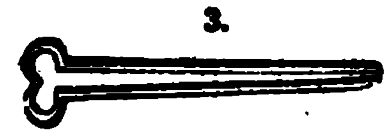
1.



The cupel is a sort of shallow crucible, made of bone ashes or burnt bones. At the Royal Mint the cupels are made of the calcined cores of ox-horns. The powder is slightly moistened with water, and a circular steel mould is filled therewith, and after being pressed down tight, is finished off with a rammer, having a convex face of polished steel, which is struck forcibly with a mallet, until the mass becomes sufficiently hard and adherent. The cupel is then carefully removed, and exposed in the air to dry, which usually takes from 14 to 21 days. Fig. 2 represents a cupel in section, and fig. 3 the tongs for charging the same. The best weight for cupels is said to be 180 to 200 grs.

2.

3.



Process of assaying. The muffle, with the cupels properly arranged, being placed in the furnace, the latter is filled up with charcoal, and lighted at the top by placing a few pieces, heated to whiteness, on last. When the cupels have been exposed for half an hour, and have become white by heat, the lead is put into them by means of the tongs, and as soon as this becomes thoroughly red and circulating, as it is called, the metal to be assayed, wrapped in a small piece of paper, is added, and the fire kept up strongly until the metal enters the lead and circulates well, when the heat may be slightly diminished, and so regulated that the assay shall appear convex and ardent, while the cupel is less red—that the undulations shall circulate in all directions, and that the middle of the metal shall appear smooth, surrounded with a small circle of litharge, which is being continually absorbed by the cupel. This treatment must be continued until the metal be-

comes bright and shining, or is said to "*lighten;*" after which certain prismatic colors, or rainbow hues, suddenly flash across the globules, and undulate and cross each other, and the latter metal soon after appears very brilliant and clear, and at length becomes fixed and solid. This is called the "*brightening*," and shows that the separation is ended. In conducting this process, all the materials used must be accurately weighed, especially the weight of the alloy before cupellation, and the resulting button of pure metal. The difference gives the quantity of alloy. The preceding general description of the process of cupellation will render the following articles intelligible, without again entering into the minutiæ of the operation.

Assayers' weights. The richness or purity of gold is expressed in carats. Pure gold is spoken of as containing 24 carats, of 12 grains each; and any other sample, containing 12, 18, 22, or any other number of parts of pure gold, in 24 parts, is said to be of so many carats fine. In the process of assaying gold, the real quantity taken is very small, generally 6 or 12 grains; and this is termed the "*assay pound.*" It is nominally subdivided into 24 carats, and each carat into 4 assay grains, and each grain into quarters, so that there are 384 separate reports for gold. When the assay pound is only 6 grs., the quarter of the assay grain will only weigh the $\frac{1}{64}$ of a grain; hence the most accurate system of weighing must be adopted.

The richness or purity of silver is either expressed in pennyweights or 1000ths. In the first case, it is supposed that the mass of silver to be examined consists of 12 equal parts, called pennyweights; so that if an ingot weighs an ounce, each of the parts will be 1-12th of an ounce. Hence, if the mass of silver be pure, it is called silver of 12 pennyweights; if it contain 1-12th of its weight of alloy, it is called silver of 11 pennyweights; if 2-12ths of its weight be alloy, it is called silver of 10 pennyweights; and so on in proportion for other qualities. It must be observed here, that the assayers give the name pennyweight to a weight equal to 24 real grains, which must not be confounded with their ideal weights. The assayers' grains are called fine grains. An ingot of fine silver, or silver of 12 pennyweights, contains, then, 288 fine grains; if this ingot contain 1-288th of alloy, it is said to be silver of 11 pennyweights and 23 grains; if it contain 4-288ths of alloy, it is said to be 11 pennyweights, 20 grains, &c. Now a certain real weight must be taken to represent the assay-weights: for instance, 36 real grains to represent 12 fine pennyweights; this, if subdivided into a sufficient number of other smaller weights, will also represent fractions of fine pennyweights and grains. Thus, 18 real grains represent 6 fine pennyweights; 3 real grains represent 1 fine pennyweight, or 24 grains; a real grain and a half represents 12 fine grains; 1-32d of a real grain represents a quarter of a fine grain, which is only 1-752d part of a mass of 12 pennyweights. The purity of silver is now more frequently expressed in 1000ths, which admits of greater accuracy.

Remarks. An assay is thought to be good when the bead is of a round form, with its upper surface brilliant, its lower one granular and dead-white, and when it separates readily from the cupel. When the surface of the bead is dull and flat, it shows that too much heat has been employed; and if the metal be silver, some may have been lost in the process, by fuming or absorption. When the bead is spongy, and of various colors, and scales of litharge still remain on the cupel, and the metal adheres strongly to the latter, too little heat has been used, and the button still retains some lead. To remedy this, the heat should be raised, and a little powdered charcoal, or a few small pieces of paper, thrown into the cupel, until the metal again begins to circulate freely. It is necessary that the lead employed in the process of cupellation should be perfectly pure. It ought, therefore, to be procured by reducing refined litharge.

ASSAY OF SILVER. I. The assay pound (usually 12 or 20 grains for silver) of the alloy for examination is accurately weighed, and then wrapped in a small piece of paper ready to undergo the process of cupellation. The quantity of lead used is not uniform; but depends on the nature of the alloy. It should be 16 times the weight of the copper presumed to be present in the sample. This, however, cannot be accurately ascertained, though an experienced assayer is generally able to guess very nearly the amount. If too much lead be used, the button obtained by cupellation will be too small, owing to some of the silver being absorbed by the cupel; and if too little be used, the button will come out too large, from still containing some copper. The importance of justly proportioning the lead to the quantity of copper present in the alloy, cannot be too much insisted on. The following table exhibits the proper quantities adapted to silver of various degrees of fineness.

Assay Table, by M. D'Arcet.

Fineness of the Silver.	Proportion of Copper in the Alloy.	Dose of Lead required, the weight of silver being one.	Relation between the Lead and Copper.
Silver at 1000	...	$\frac{3}{10}$	
950	50	3	70 to 1
900	100	7	60 to 1
800	200	10	50 to 1
700	300	12	40 to 1
600	400	14	35 to 1
500	500	16 to 17	32 to 1
400	600	do.	26·6 to 1
300	700	do.	22·8 to 1
200	800	do.	20 to 1
100	900	do.	17·7 to 1
pure copper.	1000	do.	16 to 1

Remarks. As the lead always carries off a small portion of the silver into the cupel, the assay generally comes out too low, which was ascertained by M. D'Arcet to be equal to—

For fine silver, ... $\frac{1}{1000}$

" $\frac{900}{1000}$ " . . . . . $\frac{4·3}{1000}$

" $\frac{800}{1000}$ " . . . . . $\frac{4·9}{1000}$

For $\frac{500}{1000}$	"	$\frac{4{\cdot}2}{1000}$
" $\frac{100}{1000}$	"	$\frac{0{\cdot}4}{1000}$

During the process of cupellation with silver, the button is apt to "*vegetate*," especially if it be fine silver, and therefore requires to be carefully watched; for which purpose the cupel is usually kept at a convenient part of the muffle, ready to be drawn forward if required. It has just been seen that to apportion the lead correctly requires that the title of the silver should be known; when this is not the case, it may be determined approximatively, by exposing in the cupel 0·1 part of the sample with 1 part of lead. French gold and silver coin contain $\frac{1}{10}$ of copper; British silver coin consists of $\frac{12}{13}$ of silver, and $\frac{1}{13}$ of copper; and British gold coin of 11 parts of gold and 1 of copper, or a mixture of copper and silver.

II. *Humid assay of silver.* *a.* Dissolve 10 grs. of the alloy in 100 grs. of nitric acid, sp. gr. 1·28, by the aid of heat; the solution being made in a tall stoppered glass tube, furnished with a foot; then place it in a very delicate balance, which must be brought into an exact state of equilibrium, and add the test solution gradually and cautiously until the whole of the silver be thrown down; but the utmost care must be taken not to exceed this point. The number of grains now required to restore the equilibrium of the scales gives the exact quantity of pure silver present in 1000 parts of the sample.

Test liquor. Dissolve 54·27 (54¼) grs. of pure sea salt in 9945·73 grs. (or 22 oz. and 320¾ grs. avoirdupois) of distilled water; filter, and keep the liquor in a stoppered bottle for use.

Pure sea salt. Boil together for a few minutes, in a glass vessel, a solution of salt with a little pure bicarbonate of soda; filter; add muriatic acid until the liquor be neutral to litmus and turmeric paper; then evaporate and crystallize.

Remarks. The addition of the test liquor to the solution requires the *utmost exactness.* After each addition the stopper should be placed in the tube, and the latter violently agitated for a short time, when the liquor will rapidly clear and enable us to see when the operation is concluded. We must then, as a check, add a small quantity of a solution of nitrate of silver to the liquor in the tube, after having first carefully taken the weight. If too much of the test liquor has been added, this will produce a fresh precipitate, and the assay cannot then be depended on.

Instead of weighing the quantity of test liquor used, a tube graduated into 100 parts, and holding 1000 grs., may be used instead, every division of which required to throw down the silver, will represent the $\frac{1}{10}$th of a grain. The tube being filled to the 0, is ready for use, and from being graduated downward the quantity poured out may at once be read off. Generally speaking, however, measuring does not admit of the same accuracy as weighing. The termination of the operation is clearly marked, when, on adding a minute quantity of the test liquor to the silver solution, no cloudiness occurs. (See Alkalimetry and Acidimetry.)

b. The precipitate thrown down in the last experiment may be collected in a filter of white paper, and dried, washed, and weighed. The previous weight of the paper, deducted from the gross weight of the paper and silver, will give the quantity of chloride of silver present, which multiplied by ·7533, the weight of metal in one grain of the chloride, will give the exact weight of the pure silver contained in the sample.

Remarks. Mercury is the only metal whose presence at all interferes with the process; the chloride of mercury being also thrown down by salt, as well as the chloride of silver. When no mercury is present in the precipitate, it rapidly becomes black on exposure to the light, but when it contains $\frac{4}{1000}$ or $\frac{5}{1000}$ of chloride of mercury, it remains of a dead white, with $\frac{3}{1000}$ it is not sensibly discolored by the diffused light of a room, with $\frac{2}{1000}$ only slightly darkened, with $\frac{1}{1000}$ more so, but with pure chloride of silver, the effect is very rapid and intense. When mercury is present, which is however seldom the case, the assay sample must be placed in a small crucible, and exposed to a full red heat, before solution in the acid. For the method of assaying silver by the humid way, when alloyed with gold, see Gold. Those who wish to enter fully into the subject of the humid assay of silver, are referred to Gay Lussac's Essay.

ASSAY OF GOLD. 1. This process may be divided into five operations.

I. *Cupellation.* Either 6 or 12 grs. of the alloy is the weight usually taken for the assay, to which is added 16 parts of lead for every 1 part of copper that it is presumed to contain, though considerably more lead may be used when the sample does not contain any silver; but if the reverse be the case, an excess of lead would lead to the loss of the latter metal, which ought not to be separated until the operation of parting. When silver is present an additional allowance of lead, equal to $\frac{1}{10}$ of its weight, is made on that account. When, however, the quantity of silver is small, or is not required to be estimated, it becomes of little consequence what weight of lead is employed, so long as enough be used to carry off the base metals, at the same time that the quantity is not too large for the cupel. The sample is then submitted to cupellation. This process does not require so much care for gold as silver, as none of this metal is absorbed by the cupel, or lost by evaporation, and it will safely bear the highest heat of the furnace without injury. In other respects the operation may be conducted in exactly the same manner as for silver.

II. *Quartation.* After gold has passed the cupel, it may still retain either of the other perfect metals, particularly silver. To remove the latter it undergoes the operations of quartation and parting. *Quartation* is performed by adding 3 parts of silver to one of the cupelled sample, and fusing them together, by which the gold is reduced to one fourth of the mass or even less; hence the name. In this state nitric acid will dissolve out the silver, which brings us to the next operation.

In many cases the operation of quartation is performed conjointly with that of cupellation, as in the processes of Nos. 2 and 3.

III. *Parting.* The alloy of gold and silver thus formed, is next hammered or rolled out, into a thin strip or leaf, curled up into a spiral form, and submitted to the action of nitric acid, sp. g. 1·3, diluted with half its weight of water; this being poured off, another quantity of acid, of about 1·26, and undiluted, may be employed. In each case the acid should be boiled upon the alloy for about a quarter of an hour. In the first case the quantity of fluid should be about 2½ oz., and in the second 1½ oz. The second part of the operation of parting is called the "*reprise.*" If the acid be used too strong it leaves the gold in a state of powder, otherwise the metal preserves its form throughout the process of parting. It is next carefully collected, washed, and dried.

IV. *Annealing.* The sample of pure gold has now only to be annealed, which is done by putting it into a small porous crucible, and heating it to redness in the muffle.

V. *Weighing.* The pure gold is next accurately weighed. This weight doubled or quadrupled, gives the number of carats fine of the alloy examined, without calculation.

Remarks. The loss of weight by cupellation gives the amount of copper in the sample; that after parting, the amount of silver, deducting of course the weight of silver used in the process, which is called the "*witness.*" When the sample contains but very little gold, the dry method of assaying cannot be depended on, and chemical analysis must be had recourse to.

2. (*M. Chaudet's process.*) Submit to cupellation 0·500 of the sample with 1·500 of pure silver, and 1·000 of pure lead. Form the button into a strip or riband 3 inches long, and roll it into a cornet. Boil for 3 or 4 minutes in a matrass with nitric acid of 22° Baume, decant and again boil for 10 minutes with acid of 32° Baume, again decant and repeat the last boiling with a fresh lot of acid, at 32 B. for 10 minutes longer. Next wash the cornet with pure water, put it into a small crucible permeable to water, and submit it to a dull red heat in the muffle. Lastly, cool, take it from the crucible, and weigh it.

Remarks. The above is M. Chaudet's method of assaying fine gold. It affords very perfect results.

3. (*Old French government method.*) *Oper.* "Twelve grains of the gold intended to be assayed must be mixed with 30 grs. of fine silver, and cupelled with 108 grs. of lead. The cupellation must be carefully attended to, and all the imperfect buttons rejected. When the cupellation is ended, the button must be reduced by lamination into a plate of 1½ inch, or rather more, in length, and 4 or 5 lines in breadth. This must be rolled up upon a quill, and placed in a matrass capable of holding about 3 oz. of liquid, when filled up to its narrow part. Two oz. and a half of very pure aquafortis, of the strength of 20° of Baume's areometer, must then be poured upon it; and the matrass being placed upon hot ashes, or sand, the acid must be kept gently boiling for a quarter of an hour: the acid must then be cautiously decanted, and an additional quantity of 1½ oz. must be poured on the metal, and slightly boiled for 12 minutes. This being likewise carefully decanted, the small spiral piece of metal must be washed with filtered river water, or distilled water, by filling the matrass with this fluid. The vessel is then to be reversed, by applying the extremity of its neck against the bottom of a crucible of fine earth, the internal surface of which is very smooth. The annealing must then be made, after having separated the portion of water which had fallen into the crucible: and, lastly, the annealed gold must be weighed. For the certainty of this operation, two assays must be made in the same manner, together with a third assay upon gold of 24 carats, or upon gold the fineness of which is perfectly and generally known."

"No conclusion must be drawn from this assay, unless the latter gold should prove to be of the fineness of 24 carats exactly, or of its known degree of fineness; for, if there be either loss or surplus, it may be inferred that the other two assays, having undergone the same operation, must be subject to the same error."

4. (*When the alloy contains platina.*) This alloy generally contains copper, silver, platina, and gold. The sample must be cupelled in the usual way, and the loss of weight will express the amount of copper; the button, made into a riband and treated with sulphuric acid, will indicate, by the portion dissolved, the amount of silver present. By submitting the residuum to quartation, the platina will become soluble in nitric acid. The loss after digestion in this menstruum will express the weight of that metal, and the weight of the portion now remaining will be that of the pure gold.

5. *Other methods. Assay of the touch. Jewellery, small quantities, &c.* When it is desired to ascertain the fineness of small quantities of gold, as in jewellery, &c., touch needles and stones are employed. The former are made in sets, containing gold of different finenesses and differently alloyed with copper and silver. Pieces of black pottery form excellent touch stones. The mode of using them is to mark the stone with the sample under examination, and to compare its appearance, hardness, &c. with that produced by one or more of the needles. When the two are similar, the quality is considered to be the same. They are then further examined by moistening the stroke with aquafortis when red hot.

General Remarks. The preceding is a brief notice of the most approved methods of assaying. Other ways of determining the constitution of alloys exist, which are not only easier to perform, but far more accurate. In the dry way, the causes of error are numerous, and assays made by different persons after that plan, seldom agree closer than one or two thousandths, while in the case of silver, it often amounts to $\frac{5}{1000}$ or $\frac{6}{1000}$. Thus samples of the same silver sent by the French government to be assayed at different places, gave different results.

At the Mint of Paris		895·6
"	Vienna	898·4
"	Madrid	893·7
"	Naples	891·0

the difference between the two extremes of which is $\frac{7\cdot4}{1000}$, whereas, each of these samples really contained $\frac{900}{1000}$ of pure silver. It will be thus seen, as before explained, that the assay of silver always comes out *too low*, besides being more ex-

posed to error in the operation than gold. Chemical analysis, or the humid process of assay, admits, however, of ascertaining with certainty the quantity of each metal in an alloy to a degree of exactness unattainable by the cupel.

ASSES' MILK, SUBSTITUTE FOR. *Prep.* I. Boil together one quart of new milk, one ounce each of sugar-candy and ground rice, and one drachm of eringo root bruised. Strain.

II. Mix together one ounce of lump sugar, the white of two eggs, and half a pint of the best milk, then add half a teaspoonful of sirup of tolu, and mix well.

III. Boil together a pint of water and 1 oz. of hartshorn shavings, until reduced to a jelly, then add 2 oz. of lump sugar; dissolve; when cold add 1 pint of new milk, and a teaspoonful or less of sirup of tolu.

Remarks. The above are among the best forms for this article. Others are often adopted of a very dirty class, as boiling snails, &c. with water, and so many medicaments, that I presume any thing but an article resembling asses' milk is produced. *Use.* As a beverage, a cupful with or without a spoonful of rum, three or four times a day, or ad libitum. *An old woman's remedy for consumption.*

ASTHMA. (From ἀσθμαίνω, I breathe hard.) A disease characterized by difficulty of breathing, coming on by fits, accompanied by a wheezing sound, cough, and tightness of the chest, and generally terminating in a copious expectoration, after the lapse of a few hours. Asthma is principally confined to the later periods of life, and appears in many cases to be hereditary. The fits vary from two to several hours' duration. Sometimes copious expectoration attends asthma, which has led to its division into two kinds,—dry (asthma siccum) and humid, (asthma humidum.) It is brought on by sudden exposure from heat to cold, to unwholesome effluvia, by hard drinking, full meals, violent exercise, and by cold, damp, and foggy weather.

Treatment. I. *Prev.* Avoid the above exciting causes. Seek a dry, warm, and airy situation. Wear flannel, keep the bowels regular, and the stomach in order. *Cure.* The severity of the paroxysm may be lessened by adopting the sitting posture, and inhaling the vapor of hot water, or an infusion of chamomile. Emetics and diaphoretics, followed by mild purgatives, may also be administered with advantage. Various other remedies have also been recommended; among the principal are tobacco and stramonium smoking. In using the latter herb, the root and lower parts of the stem are chopped up and placed in the bowl of a common tobacco-pipe, and a few whiffs are occasionally taken. Drinking at the same time should be avoided. Lately the lobelia inflata, or Indian tobacco, has been highly extolled in asthma. The dose of the tincture is from 20 drops to ʒij. A light nutritious diet and strictly regular habits should be adopted, which will often produce a marked improvement and effect a cure, when medicines have failed. The use of bark or bitters will tend to improve the general tone of the system.

ASTHMA, DRAUGHT FOR. *Prep.* Vinegar of squills, ʒss; ipecacuanha wine, 15 drops; cinnamon water, 1½ oz.; mix for a draught to be taken three times daily. Expectorant.

ASTHMA, MIXTURE FOR. *Prep.* I. (*Expectorant.*) Milk of gum ammoniacum 3 oz., sirup of squills 2 oz., wine of ipecacuanha 1 oz.; mix. *Dose.* A small teaspoonful 4 or 5 times daily.

II. (*Tonic.*) Infusion of cascarilla 3 oz., infusion of gentian 2 oz., simple sirup 1 oz.; mix. *Dose.* Two tablespoonfuls 3 times a day.

ASTHMA, PILLS FOR. I. (*Expectorant.*) Compound squill pill 20 grs., calomel 5 grs., powdered opium 3 grs.; make them into 6 pills. *Dose.* One or two at bedtime. Expectorant, and sometimes laxative.

II. (*Tonic.*) Compound iron pills, 2 drachms, extract of gentian, 1 drachm; mix, and divide into 60 pills. *Dose.* Two night and morning.

ASTRINGENTS, (In Medicine.) Substances that constrict the animal fibre, and coagulate albumen. When employed to check bleeding, they are called styptics. The principal *vegetable astringents* are *catechu, kino, galls,* and *oak bark;* the principal *mineral astringents* are *sulphate of iron, nitrate of silver, chloride of zinc, sulphate of copper, acetate of lead,* &c.

ASTRINGENT COLLYRIUM. *Prep.* Compound liquor of alum, ½ oz., rose water, 5½ oz., laudanum, 60 drops. *Use.* For weak eyes.

ASTRINGENT PILLS. *Prep.* Alum, 6 grs., extract of opium, 1 gr., powdered catechu, 20 grs.; divide into 6 pills. *Dose.* One after each motion in diarrhœa.

ASTRINGENT POWDER. Powdered galls and burnt alum, of each equal parts, in very fine powder; mix. *Use.* For piles and soft polypi of the nose.

ATMOSPHERE, PURITY OF. *Test.* A simple method of ascertaining the presence of impurity (carbonic acid) in the atmosphere, is to nearly fill a glass tumbler with limewater, and to place it in any convenient position, as on the mantel-piece of a room. The rapidity with which a pellicle forms on its surface, or the water becomes cloudy, corresponds to the amount of the carbonic acid present in the atmosphere that surrounds it. II. A little moist carbonate of lead put on a plate or saucer, and exposed in the same way, will turn black, should any sulphureted hydrogen be contained in the air. This is a very delicate test for that destructive gas.

ATROPIA. *Syn.* Atropina. Atropine. Atropium. An alkaloid, or vegetable alkali, discovered in the atropa belladonna, by Brande. *Prep.* I. Make an aqueous decoction with 2 lbs. of the dried leaves of the deadly nightshade, press out the liquor, and boil them a second time; mix the two waters, and add a little sulphuric acid; then filter, supersaturate the liquor with potash, collect the precipitate, wash with cold water, and dry it. The product is 89 grs. This must then be purified by repeated solutions in dilute acid, the use of animal charcoal, and precipitation by an alkali. According to Mein and Thompson, 1 oz. of the root of belladonna yields 1 gr. of pure atropia.

II. Add freshly precipitated hydrate of magnesia to the filtered expressed juice of belladonna, evaporate to dryness as quickly as possible in a water bath, then pulverize the residuum, and digest it in strong alcohol; decant the clear liquid,

and allow it to evaporate spontaneously. The crystals may be purified by repeated resolutions in alcohol.

Remarks. This alkaloid is a powerful narcotic poison. In quantity scarcely appreciable, it occasions dilatation of the pupil, when applied to the eye. The $\frac{1}{10}$ of a grain causes very serious effects in the human subject. It is volatile at common temperatures, and rises in vapor at 212°; hence the danger of experimenting on this substance. Brande suffered so much from this cause, that he was compelled to discontinue his experiments on the properties of this alkali. It forms salts with many of the acids, which may be crystallized. They may be made by saturating the dilute acids with the bases.

ATROPIC ACID. Richter has given this name to a volatile and crystallizable acid, resembling the benzoic, extracted from the atropa belladonna, or deadly nightshade. (Pharm. Centr. Blatt. 1837, s. 614.)

ATROPHY. *Syn.* ATROPHIA. A wasting of the whole body. *Cause and Treatment.* This is generally produced by the body receiving an insufficient supply of nourishment, arising from imperfect digestion, diarrhœa, and in children, very frequently from worms. The best treatment is to keep the bowels regular, and to administer mild tonics, or alteratives, accompanied with a nutritious diet; cleanliness, fresh air, and moderate exercise are also essential. When worms are the cause, attempts should be immediately made to remove them. (See ANTHELMINTICS.)

AURANTIIN. The bitter principle extracted from the peel of the orange and lemon.

Prep. The exterior peel separated from the white matter, should be well dried by free exposure to warm dry air, until it has nearly lost its fragrance. It is then to be boiled with water, and the liquor strained off and evaporated to dryness. Purify by frequent solution in alcohol.

Prop. Possesses the bitter properties of the peel in a concentrated state, without any of its fragrance.

AURO-CHLORIDES. *Prep.* These salts may be prepared by mixing the terchloride of gold with the chloride of the base, in atomic proportions, and setting aside the solution to crystallize.

Prop. Most of the auro-chlorides crystallize in prisms, dissolve in both alcohol and water, have an orange or yellow color, and are decomposed at a red heat.

AURO-CHLORIDE OF HYDROGEN. Formed by cautiously evaporating an acid solution of terchloride of gold.

AVIARY, (from *avis*, a bird.) A place for keeping birds. *Situation, &c.* In constructing an aviary for exotic birds, a place should be selected where the temperature can be kept at a proper degree throughout the year, and which is well protected from the weather. This is most conveniently done by choosing a space attached to the summer or hot house. When the aviary is only intended for birds of climates similar to our own, any part of the open garden may be chosen, and a portion closed in. Among the commoner exotic birds kept in aviaries, are canaries, turtle-doves, parrots, and paroquettes; and among those inhabiting climates resembling Great Britain, are gold and silver pheasants, and the finer varieties of pigeons. Among aquatic birds may be mentioned black and white swans, Muscovy ducks, &c., all of which, however, require good protection from the vicissitudes of the weather.

AZOBENZIDE. *Prep.* Add solid hydrate of potassa to nitro-benzide, dissolved in alcohol in a retort; apply heat and distil the red solution. The first portion which comes over is alcohol, and the next azobenzide, which must be collected separately.

Remarks. Form. Large red crystals. Discovered by Mitzcherlitz.

AZOBENZULE. *Prep.* The residuum of the preparation of benzhydramide boiled with 100 parts of alcohol, deposites crystals of azobenzule on cooling. Form, a white crystalline powder.

AZOERYTHRINE. A substance extracted by Kane from Orchil. It is insoluble in alcohol, ether, and water; but very soluble in alkaline lyes, to which it imparts a port-wine color. (Phil. Trans. 1840, p. 273.)

AZOLITMINE. A substance extracted by Kane from litmus. It is insoluble in water and alcohol; soluble in alkaline lyes. It forms the principal ingredient in litmus.

AZOMARIC ACID. An acid discovered by Laurent during his researches on the turpentine of the pinus maritima. It is formed by submitting pimaric acid to the action of nitric acid.

AZURE, EGYPTIAN. *Prep.* Carbonate of soda 1 lb.; calcined flints 1½ lb.; copper filings ¼ lb.; all in fine powder. *Proc.* Mix and fuse them together in a crucible for 2 hours. When cold, reduce to an impalpable powder.

Remarks. This is a most beautiful and permanent sky-blue color. It is used in painting, and as a substitute for smalts.

AZURE, PIGMENT. *Prep.* Quicksilver 2 oz.; sulphur and sal ammoniac, of each ½ oz. *Proc.* Grind well together, and place the ingredients in a matrass, which must be exposed to a slow fire until an azure fume arises; then cool and powder. (Mackenzie.) *Remarks.* This form is stated to produce a color nearly equal to ultramarine, but I much doubt it.

BACHER'S PILLS. *Prep.* Extract of black hellebore and powdered myrrh, of each 1 oz.; carduus benedictus (blessed thistle) 3 oz.; mix and divide into 1-grain pills. *Dose.* 2 to 6 three times a day. Tonic.

BACON. *Qual.* When this article has been properly prepared from healthy meat, and is neither old nor rusty, it forms a very wholesome and excellent food, especially when eaten with vegetables. It is too strong, however, for the stomachs of very delicate persons, and should therefore be avoided by them. *Choice.* Good bacon has a thin rind, the fat has a firm consistence and reddish tinge; the lean has a pleasing red color, is tender, and adheres strongly to the bone. The streaky parts are the most esteemed as well as the most wholesome. When the fat has a yellowish tint, it is rusty, or becoming so, and should be avoided.

BAILEY'S ITCH OINTMENT. This consists of nitre, alum, sulphate of zinc, cinnabar, olive oil, and lard, scented with the essential oils

of aniseed, origanum, and lavender, and colored with alkanet.

BAKER'S ITCH. *Syn.* PSORIASIS DIFFUSA. This disease is of common occurrence on the hands of bakers; hence the vulgar name. *Treat.* Frequent ablution in warm water, keeping the bowels open with saline purgatives, and the nightly use of the following ointment will generally effect a cure. Salt food should be avoided as much as possible, as well as keeping the hands covered with dough and flour; the latter being the cause of the disease.

BAKER'S ITCH, OINTMENT FOR. Mix well together ½ oz. of ointment of nitrate of mercury, and 1 oz. of palm oil.

BAKING. (IN COOKERY.) One of the cheapest and most convenient ways of dressing dinners for small families. Though the flavor of baked meat is generally considered barely equal to the same roasted, yet there are some joints and dishes to which it appears particularly suitable. Among these may be mentioned legs and loins of pork, legs and shoulders of mutton, fillets of veal, &c. A baked pig, if it has been occasionally basted with melted butter during the operation, and the heat has not been too great, will eat equal to a roasted one. Geese and ducks treated in the same way are also excellent. A hare prepared in the same way as for roasting, and basted occasionally with milk and melted butter, will also eat well; so will various pieces of beef, especially the buttock. The latter should be prepared as follows:—After it has been salted about a week, it should be washed and put into a brown earthen pan, glazed inside, with about a pint of water; it should then be tied over with writing-paper, three or four times thick, and baked for 4 or 5 hours in a lightly-heated oven. A baked ham is preferable to a boiled one; it not only eats much tenderer, but cuts fuller of gravy, and has a finer flavor. Before being baked it should be soaked in clean water for an hour, then wiped dry with a towel, and covered with a thin paste or batter.

Much of the prejudice that exists against baking arises from the careless manner in which it is usually performed by the bakers, and also from so many different dishes, possessing such various flavors and odors, being baked together in the same oven.

BALDNESS. *Cause.* This is generally produced by fever or old age, but is sometimes found in comparatively young persons, enjoying perfect health. *Remarks.* When the hair bulbs have disappeared, there is no means known that will restore the hair, notwithstanding the daily assurances to the contrary, by numerous advertising impostors. When a disposition to baldness exists, or when the hair falls off in large quantities, the constant use of the hair-brush, and any emollient oil or pomatum, scented with some stimulating aromatic, will generally prove sufficient. Should this not succeed, the head should be shaved. The following formulæ tend to strengthen the hair, and to keep the head clean.

BALDNESS, OIL FOR. *Prep.* Salad oil 1 oz.; oil of origanum 12 drops; oil of rosemary 10 drops; oil of lavender 6 drops; oil of cloves 2 drops; mix and shake well together.

BALDNESS, POMMADE FOR. *Prep.* Beef suet 1 oz.; tincture of cantharides 1 teaspoonful; oil of origanum and bergamotte, of each 10 drops. *Proc.* Melt the suet, and when nearly cold, add the rest and stir until set.

BALDWIN'S PHOSPHORUS. *Prep.* Evaporate to dryness an aqueous solution of nitrate of lime, and continue the heat until the nitrate be fused, in which state it must be kept for 5 to 10 minutes, and then poured out into an iron pot, previously made warm, and allowed to cool gradually; after which, break it into pieces and put it into well-stopped vials. *Prop.* After exposure to the sun for some time, it emits a beautiful white light in the dark.

BALLOONS. BALLOONING. *Syn.* BALLON (*Fr.*) AERONAUTICS, (the art of sailing in and navigating the air.) AEROSTATION, (*properly, weighing the air, but frequently used to imply the art of raising substances into the atmosphere by means of balloons.*) AERONAUT, (*literally, an air-sailor,*) *one who travels in a balloon. Hist.* There appears to have been an inherent desire in man, from the most remote antiquity to the present time, to assume a similar sovereignty over the air that he possesses over the sea. The story of Dædalus and the fate of Icarus, must be familiar to every classical reader. The account of the automaton dove, constructed by the geometer Archytas, appears to have been no fable. During the middle ages many attempts were made at flying, but it was not until the eighteenth century that any efforts of this nature were crowned with success. In the year 1782, the brothers Montgolfier constructed a balloon, which was inflated with the smoke produced from the combustion of damp straw, and in 1783, Pilatre de Rozier and the Marquis d'Arlandes ascended in a smoke balloon, from Paris, to an elevation of upwards of 3000 feet. In the beginning of 1784, MM. Charles and Robert ascended in a balloon filled with hydrogen gas, and after a flight of 90 minutes, alighted in safety. Other successful ascents followed, and no accident occurred until the young naturalist, Pilatre de Rozier, and his companion Romain, lost their lives in attempting to cross the channel from France to England. The machine on this occasion was double, having a large upper balloon filled with hydrogen, and a smaller one below (for the sake of raising or sinking the machine at pleasure) inflated with smoke. At a height of 3000 feet, the whole apparatus was discovered to be on fire, and the unfortunate aeronauts were precipitated to the ground. The victory of Jordan over the Austrians at Fleurus in 1794, is said to have been obtained from the knowledge he acquired of the enemy's movements by means of a balloon. An ascent, very interesting to science, was made by Biot and Gay Lussac in 1804, when an elevation of upwards of 13,000 feet was attained. A similar ascent was made soon after by Gay Lussac alone, when the enormous height of 23,040 feet was reached, or an elevation of upwards of 4¼ English miles, being higher than the highest peak of the Andes. Since that time to the present numerous ascents have taken place in most of the principal towns of England, and in the majority of these cases, the balloons have been inflated with coal gas, furnished by the gas works The feat of Mr. Green, who ascended in a gigantic balloon from

Vauxhall in November, 1836, and succeeded in safely conducting across the channel to Nassau in Germany, not only himself, but two companions and a ton of ballast, must be within the recollection of every one, and the more recent "*jugglery*" of Mr. Henson and his "*phantom*" aerial machine, must be still more familiar.

Principles of Ballooning. The weight of the body of air which a balloon displaces, must exceed the gross weight of the balloon and all its appendages. Pure hydrogen is 16 times lighter than common air at the earth's surface; but when prepared on the large scale for ballooning, it is only from 7 to 11 times lighter. (Cavendish.) Hence a bag, filled with this gas, will ascend to a position in the atmosphere where the latter possesses a similar density to itself, allowing, of course, for the addition to the gravity of the gas, occasioned by the weight of its envelope. It has been computed that a balloon of 60 feet diameter, filled with common hydrogen gas, prepared from iron filings and acid, on the large scale, and being 6 times rarer than the atmosphere, would raise a weight of nearly 7000 lbs., besides the weight of the gas case, while one of only 1½ feet in diameter would barely float, from the less proportion of gas to the weight of the case that contains it. The *aerostatic* power of balloons is proportional to their dimensions in the ratio of the cubes of their diameters. Balloons are made of larger size than required to contain the necessary quantity of gas, to allow room for its increase of bulk, as it rises into a rarer medium. A foot of gas, measured at the earth's surface, will fill a space of two feet at an elevation of 3½ miles. The carbureted hydrogen, supplied by the gas-works, is much heavier than hydrogen gas, and consequently, a balloon filled with the former has a much less ascensional power than when filled with the latter. *Materials, &c.* The fabric, of which *air balloons* are made, is strong, thin silk, covered with a varnish of Indian rubber. *Fire balloons* (on the small scale) are generally made of silver paper, and inflated by burning spirits of wine, by means of a sponge dipped therein, and suspended just within the mouth of the balloon. The following table of the diameters, surfaces, and capacities of spheres, as well as the remarks that follow, are taken from the Chemical Dictionary of Dr. Ure.

Table showing the relations between the diameters, surfaces, and capacities of spheres. By Dr. Ure.

Diameters.	Surfaces.	Capacities.
1	3·141	0·523
2	12·567	4·188
3	28·274	14·137
4	50·265	33·51
5	78·54	65·45
10	314·159	523·6
15	706·9	1767·1
20	1256·6	4189·
25	1963·5	8181·
30	2827·	14137·
40	5026·	33510·

Remarks. Having ascertained by experiment the weight of a square foot of the varnished cloth, we find, by inspection in the above table, a multiplier, whence we readily compute the total weight of the balloon. A cubic foot of atmospheric air weighs 527 grs., and a cubic foot of hydrogen about 40. But as the gas employed to fill balloons is never pure, we must estimate its weight at something more. And perhaps, taking every thing into account, we shall find it a convenient and sufficiently precise rule for aerostation, to consider every cubic foot of included gas to have by itself a buoyancy of fully one ounce avoirdupois. Hence, a balloon of 10 feet diameter will have an ascensional force of fully 524 oz. or 33 lbs. *minus* the weight of the 314 superficial feet of cloth; and one of 30 feet diameter, a buoyancy of fully 14,137 oz., or nearly 890 lbs. *minus* the weight of the 2827 feet of cloth. On this calculation no allowance need be made for the seams of the balloon.

BALLOON VARNISH. I. Good boiled linseed oil, if allowed a sufficient time to dry and harden, forms an excellent varnish for balloon cases.

II. Indian rubber 1 lb., (cut small;) oil of turpentine 6 lbs.; boiled drying oil 1 gallon. *Proc.* Digest the Indian rubber in the turpentine, in a warm place, for a week, frequently shaking the vessel during the whole time, then place it in a water bath and gradually heat it until the solution be completed; next add the oil, previously made warm, gently simmer for five minutes, stirring all the while, after which closely cover it over, and when cold strain it through flannel.

III. *Ing.* Birdlime 1 lb.; boiled linseed oil 3 pints; turpentine q. s. *Proc.* Boil the birdlime with 1 pint of the oil in an iron pot, over a slow fire, for about half an hour, or until the former ceases to cackle, then add the rest of the oil, previously heated, and again boil for about one hour, stirring well all the time, being careful that it does not boil over, as it is very liable to do so. When it has boiled sufficiently, may be known by its admitting of being drawn into threads between two knives. As soon as this occurs, remove the pot from the fire, and when cooled a little, add a sufficient quantity of spirits of turpentine (warm) to reduce it to a proper consistence, and work it well up.

Remarks. These varnishes are better applied lukewarm to the silk, previously stretched out tight. In about 24 hours they will dry.

BALLS, ALTERATIVE, (for Horses.) *Prep.* I. *Ing.* Calomel ½ oz.; powdered aloes 1½ oz.; starch 6 oz.; soft soap 8 oz. *Proc.* Make them into a mass, and divide into 12 balls. *Use.* To improve the constitution.

II. *Ing.* Tartar emetic and powdered ginger, of each 5 oz.; powdered opium and calomel, of each 1 oz.; treacle to mix. Divide into 16 balls.

III. Powdered Barbadoes aloes, ginger, and liquorice, of each 2 oz.; all in powder; Castile soap 2 oz.; treacle to mix; divide into 6 balls. *Use.* For grease.

IV. Barbadoes aloes, emetic tartar, and liquorice, of each 1 oz.; Castile soap, 2 oz.; treacle to mix. For 4 balls. *Use.* For strangles.

V. Calomel, sulphuret of antimony, and powdered opium, of each ½ oz.; powdered gum guaiacum 2½ oz.; Castile soap 12 oz.; treacle to mix. Divide into 12 balls. *Use.* For weak horses with a bad constitution.

VI. Calomel ½ oz.; cascarilla and rhubarb, of each 1 oz.; aloes and soap, of each 4 oz.; treacle to mix. For 12 balls. *Use.* For weak horses.

BALLS, ANODYNE, (FOR HORSES.) Opium and camphor, of each ¼ oz.; aniseed powder 2 oz.; ginger 1 oz.; oil of caraways ¼ oz.; Castile soap 1½ oz.; treacle to mix. Divide into 3 balls. *Warming, Composing.*

BALLS, ASTRINGENT, (FOR HORSES.) I. Opium ¼ oz.; carbonate of soda 1 oz.; powdered cassia and ginger, of each ½ oz.; powdered gentian 2 oz.; treacle to mix. For 4 balls. *Tonic and binding.*

II. Opium ½ oz.; ginger ¼ lb.; prepared chalk ½ lb.; treacle to mix. For 10 balls. *For looseness.*

III. Gum catechu ¾ oz.; powdered ginger 1 oz.; powdered liquorice 2 oz.; soft soap to mix. For 3 balls. *Astringent* and *tonic.*

BALLS, BITTER. *Ing.* Powdered gentian 2 lbs.; extract of gentian 1 lb.; treacle q. s. *Proc.* Beat the ingredients to a hard mass, and make it into ½ lb. rolls. *Use.* Substituted for hops by fraudulent brewers.

BALLS, BLACK. *Syn.* BLACKING BALLS. I. Beeswax 8 oz.; resin 1 oz.; tallow ½ oz.; melt together, then add gum arabic 1½ oz.; dissolved in water 2 oz.; and as much lamp-black as necessary to color; stir until nearly cold, then run it into tin moulds.

II. Lard and wax, each 1 oz.; ivory black, lampblack, and brown sugar, of each 8 oz.; best size 4 oz.; mix as above.

III. Ivory black 16 oz.; gum tragacanth 2 oz.; sugar candy 4 oz.; water 16 oz.; mix with heat.

IV. Ivory black and lampblack, of each 16 oz.; thick mucilage of gum arabic 7 oz.; brown sugar 6 oz.; melted glue 1 oz.; water 1 quart, as above.

V. Suet 4 oz.; beeswax and sweet oil, 1 oz. each; sugar candy and gum arabic, both in fine powder, 1 drachm each; melt together over a slow fire, then add one tablespoonful of turpentine, and enough lampblack to produce a good color. Mould as above. *Use.* For blacking leather.

BALLS, BREECHES. *Ing.* Bath brick 1 lb.; pumice-stone ½ lb.; all in fine powder; ox-gall 6 oz. *Proc.* Make them into a paste, with a little water, if required, and mould them of any shape you please.

II. Mix together equal parts of whiting and pipeclay, to which some coloring may be added. *Remarks.* Rose pink, yellow ochre, umber, Irish slate, or any other similar coloring matter may be added to produce the desired tint.

BALLS, CAMPHOR, (FOR HORSES.) I. Camphor 1 oz., (reduce it to powder by adding a little spirit and rubbing it in a mortar;) powdered nitre 4 oz.; liquorice powder 1 oz.; treacle to mix. For 4 balls. *Anodyne* and *diuretic.*

II. Omit the nitre, and add 4 oz. more liquorice powder. *Anodyne.*

BALLS, CLOTHES. I. Pipeclay 2 lbs.; fuller's earth 1 lb.; whiting ½ lb.; white pepper 3 oz.; mix with water.

II. Fuller's earth 2 lbs.; curd soap 1 lb.; ox-galls sufficient to make a stiff dough, with which form balls.

Use. To remove grease from cloth and to clean clothes.

BALLS, COLIC, (FOR HORSES.) Powdered opium ¼ oz.; Castile soap and camphor, each 1 oz.; powdered ginger and cassia, each ½ oz.; liquorice powder 2 oz.; treacle to make 4 balls.

BALLS, CORDIAL, (FOR HORSES.) Aniseed, caraway-seed, and cumin-seed, of each 4 lbs.; ginger 2 lbs.; all in powder; treacle q. s. to mix. Product 21 lbs. To be made up into balls weighing 1¾ oz. each.

II. Powdered ginger 1 lb.; liquorice powder 3 lbs.; whiting 2 lbs.; powdered opium 1 oz.; oil of caraway ½ oz.; oil of cassia ¼ oz.; oil of nutmegs and cloves, each 1 drachm; treacle to mix. Divide into balls 1½ oz. each.

III. Starch and powdered ginger, of each ½ lb.; oils of caraway, cassia, and cloves, of each ¼ oz.; treacle to mix. Divide into 12 balls. *Use.* As a cordial after looseness, (especially No. II.,) during colds, &c.

BALLS, COUGH, (FOR HORSES.) I. Cordial ball mass 4 lbs.; gum ammoniacum 4 oz.; powdered squills 1 oz.; treacle to mix. Divide into 4 dozen balls.

II. Powdered ipecacuanha 1 oz.; powdered squills, camphor, and oil of aniseed, of each ½ oz.; liquorice powder 16 oz.; treacle to mix. For 12 balls.

III. Gum ammoniacum 3 oz.; powdered squills 1 oz.; camphor ¾ oz.; opium ½ oz.; powdered ginger 2 oz.; oil of aniseed 5 drachms; treacle to mix. For 8 balls.

BALLS, CREAM. White curd soap 1 lb.; powdered starch 3 oz.; beat together, weigh into 1 oz. balls, and roll them in powdered starch. *Use* For cleaning the hands.

BALLS, DIAPHORETIC, (FOR HORSES.) I. Antimonial powder 1 oz.; camphor ¾ oz.; starch 6 oz.; mix with treacle, and divide into 6 balls.

II. Tartar emetic and camphor, of each ¼ oz.; liquorice powder 2 oz.; make them into two balls, with treacle.

III. Camphor 1 oz.; sal ammoniac 3 oz.; liquorice powder 2 oz.; oil of aniseed ¼ oz.; soft soap 8 oz.; beat together, and divide into 6 balls.

BALLS, DIURETIC, (FOR HORSES.) I. Soft soap and Venice turpentine, of each 4 oz.; powdered nitre 2 oz.; oil juniper, ½ oz.; liquorice powder 3 oz. Divide into 8 balls.

II. Powdered nitre, rosin, and soft soap, of each 4 oz.; liquorice powder 5 oz.; oil of juniper 1 oz.; treacle to mix. For 12 balls.

III. Powdered rosin 6 lbs.; nitre 4 lbs.; soft soap and Venice turpentine, of each 1 lb.; oil of juniper 1 oz.; treacle to mix. Weigh into 1¾ oz. balls.

BALLS, FARCY, (FOR HORSES.) Corrosive sublimate 10 grains; liquorice powder 1 oz.; oil of aniseed ½ a drachm; mix with treacle for 1 ball.

II. Calomel 1 oz.; powdered opium ½ oz.; liquorice powder 12 oz.; mix with treacle for 12 balls.

BALLS, FEVER, (FOR HORSES.) Tartar emetic 2 oz.; nitre 8 oz.; liquorice 6 oz.; all in fine powder; mix with treacle for 12 balls.

II. Nitre and tartar emetic, of each 1 lb., in fine powder; powdered digitalis 4 oz.; antimonial powder 8 oz.; liquorice powder 1½ lb.; treacle to mix. Divide into balls weighing 1 oz. 3 drs. each.

BALLS, FURNITURE. I. Melt together in a pipkin 1 lb. of beeswax and ¼ oz. of alkanet root until the former be well colored; then add linseed oil and spirits of turpentine, of each ½ pint. Strain through a piece of coarse muslin.

II. Linseed oil 1 pint, alkanet root 2 oz.; heat them together until a proper color be produced, strain, and add yellow wax 1¼ lb., and rosin 2 oz. *Use.* For polishing furniture.

BALLS, GARLICK, (FOR HORSES.) Garlick 1 oz.; liquorice powder enough to make a ball. *Use.* For chronic coughs.

BALLS, GRIPE, (FOR HORSES.) Liquorice, black pepper, ginger, and prepared chalk, all in powder, of each 4 oz.; oils of caraway, cloves, and cassia, of each 1 drachm; treacle to mix. For 12 balls.

BALLS, INFLUENZA, (FOR HORSES.) Barbadoes aloes, nitre, and Venice turpentine, of each 1 lb.; gentian 2 lbs.; ginger ½ lb.; treacle to mix. Divide into 1½ oz. balls.

BALLS, LAXATIVE, (FOR HORSES.) I. Aloes, ginger, and soft soap, of each 3 drachms; mix with treacle for 1 ball. Cordial and laxative.

II. Flowers of sulphur ¾ lb.; powdered antimony 2 oz.; calomel 1 oz.; powdered ginger 3 oz.; treacle to mix for 12 balls.

BALLS, MANGE, (FOR HORSES.) Crude antimony 2 oz.; calomel 1 oz.; opium ½ oz.; flowers of sulphur 1 lb.; mix with treacle and divide into 12 balls. *Remark.* A piece the size of a horse bean to that of a small nut, is a capital medicine for dogs.

BALLS, MERCURIAL, (FOR HORSES.) I. Calomel 1 oz.; aloes 2 oz.; rhubarb ¾ oz.; liquorice powder 14 oz.; treacle to mix. Divide into 12 balls. Laxative and alterative.

II. Strong mercurial ointment ¼ lb.; powdered ginger 3 oz.; liquorice powder 10 oz.; treacle to mix for 12 balls.

BALLS, PHYSIC. *Syn.* PURGING BALLS, (FOR HORSES.) Barbadoes aloes 5 oz.; hard soap 3 oz.; ginger and olive oil, of each 1 oz.; melt together in a ladle, and while warm, divide into 6 balls.

II. Aloes and hard soap, of each 5 oz.; pearlashes 1 oz.; powdered ginger 2 oz.; melt as above for 8 balls.

BALLS, SCOURING. I. *Ing.* Curd soap 8 oz.; oil of turpentine and ox-gall, of each 1 oz. *Proc.* Melt the soap, and when cooled a little, stir in the rest, and make it into cakes while warm.

II. Soft soap and fuller's earth, each 1 lb.; beat them well together in a mortar, and form into cakes. *Use.* To remove grease, &c., from cloth. The spot first moistened with water is rubbed with the cake, and allowed to dry, when it is well rubbed with a little warm water, and afterwards rinsed or rubbed off clean.

BALLS, STOMACHIC, (FOR HORSES.) Powdered gentian, 4 oz.; powdered ginger and carbonate of soda, each 2 oz.; soft soap 8 oz.; mix and divide into 8 balls.

II. Powdered quassia, myrrh, soda, aloes, and rhubarb, of each 2 drachms; oil of cloves 10 drops; treacle to mix for 1 ball.

III. Aloes ½ oz; rhubarb and ginger, each ¼ oz.; calomel 1 drachm; oil of caraway 10 drops; soft soap 3 drachms; for 1 ball.

BALLS, STRENGTHENING, (FOR HORSES.) Powdered calomba and cascarilla, of each ¼ oz.; soft soap ¾ oz.; chalk ½ oz.; make into a ball, *for looseness, &c.*

II. Powdered gentian 2 oz.; sulphate of iron and myrrh, of each 1 oz.; liquorice powder 4 oz.; treacle to mix. For 8 balls.

BALLS, SULPHUR, (FOR HORSES.) Flowers of sulphur 1 lb.; powdered antimony 3 oz.; red sulphuret of mercury (pure) 2 oz.; powdered gum 1 oz.; treacle to mix. For 12 balls. Said to make the coat sleek; also for mange, &c.

BALLS, SWEET. *Syn.* POMAMBRA. I. *Ing.* Florentine orris root 3 oz.; cassia 1 oz.; cloves, rhodium wood, and lavender flowers, of each ½ oz.; ambergris and musk, of each 6 grs.; oil of verbena 10 drops. *Proc.* Make them into balls with mucilage of gum tragacanth made with rose-water.

II. Gum benzoin and styrax, of each 1 oz.; cloves and cassia, of each ¼ oz.; musk and civet 5 grs.; balsam of Peru, oil of verbena, oil of rhodium, otto of roses, and true neroli, of each 10 drops; Florentine orris root 2 oz. *Proc.* Reduce the dry articles to powder, then add the essences, and make the whole into balls with essence of jessamine, jonquil, violet, and tuberose, of each equal parts.

III. Plaster of Paris 4 oz.; sandal wood, cyperus root, and cloves, of each ½ oz.; gum benzoin and styrax, of each 1 oz.; ivory-black 2 oz.; musk and civet, of each 1 scruple; ambergris 10 grains; balsam of Peru ½ oz.; oil of cassia 10 drops; oil of rhodium ½ a drachm; essence of jasmin ¼ oz.; essence of neroli ½ a drachm; otto of roses 15 drops; mucilage made with orange-flower water to mix. *Proc.* Make them into beads, and pierce them while soft.

Use. Worn in the pocket as a perfume. Some persons varnish them, but that keeps in the smell.

BALLS, TONIC, (FOR HORSES.) Gentian ½ oz.; opium ½ a drachm; cascarilla, myrrh, and carbonate of soda, of each 1 drachm; soft soap ½ oz. Form into a ball.

II. Calomba 2 oz.; cassia ½ oz.; allspice ½ oz.; treacle to make 2 balls.

III. Powdered bark 8 oz.; gentian 2 oz.; salts of tartar 1 oz.; opium ½ oz.; liquorice powder and iron filings, of each 3 oz.; treacle to make 12 balls. If the horse is costive, omit the opium.

IV. Sulphate of iron 4½ oz.; powder of calomba 5 oz.; do. of cascarilla 3 oz.; soft soap 8 oz. For 12 balls.

V. Sulphate of iron, myrrh, and gentian, of each, ½ oz.; ginger ½ oz.; carbonate of soda 3 drachms; treacle to make 1 ball. The last three are suited for washy horses.

VI. Gentian 8 oz.; ginger 4 oz.; opium ¾ oz.; nitre 3 oz.; oil of caraway ½ oz.; liquorice powder and treacle to make 12 balls. For excessive staling.

VII. Sulphate of iron and sulphate of copper, of each, 1 drachm; Venice turpentine 1 oz.; ginger and cassia, of each, ¼ oz.; liquorice powder to make 2 balls. For incontinence of urine.

BALLS, WORM, (FOR HORSES.) I. Aloes 5 drachms; Castile soap ½ oz.; calomel and ginger, of each, 1½ drachms; oil of cloves and cassia, of each, 6 drops; treacle to make a ball. II.

Aloes, powdered tin, ginger, and soft soap, of each, ½ oz.; oil of cloves 15 drops. Make a ball.

BALLS, WASH, (MOTTLED.) I. (*Red.*) Cut white curd or Windsor soap, not too dry, into small square pieces, and roll them in a mixture of powdered bole and starch, or bole alone; then squeeze them into balls without mixing the color more than is necessary.

II. (*Blue.*) Roll the pieces in powdered blue, and proceed as before.

III. (*Green.*) Roll the pieces in a mixture of powdered blue and yellow ochre.

Remarks. In this way, by varying the color of the powder, mottled wash-balls of any color may be produced.

BALM OF GILEAD. *Syn.* BALSAMÆLEON. OPOBALSAM. OIL OF BALSAM. BALM OF MECCA. BALSAMUM JUDAICUM. The genuine balsam of Mecca is the juice of the amyris gileadensis, and is obtained by cutting the bark of the tree with an axe. It is both scarce and costly, and *none* of it ever reaches this country as an article of commerce. "There are only two shops in Constantinople at which the genuine balsam can be obtained. Its price is exorbitant, one grain being charged 5 Turkish piastres = 1s. 0½d." That which is sent to England is obtained by boiling the twigs of the balsam tree in water. The real balsam of Mecca is of a clear gold color, and possesses a penetrating and delicate fragrance, and a sharp bitter astringent taste. A drop let fall on the surface of hot water spreads itself over the whole surface, like a thin film of oil, and again contracts on the water cooling. It dissolves completely in fatty and essential oils, which then assume the peculiar flavor of the balsam. *Use.* It is thought to be antiseptic, stimulant, and vulnerary, and that its fumes prevent barrenness. It is employed in the east as a cosmetic and perfume. When applied to the skin it causes redness and swelling.

BALM OF GILEAD, FACTITIOUS. The article met with in trade under the name of balm of Gilead is either the article alluded to above or a spurious kind prepared by one of the formulæ below.

I. *Ing.* Yellow rosin 10 oz.; tincture of benzoin and oil of lemons 3 oz. each; oils of caraways and rosemary, of each, 2 oz. *Proc.* Melt the rosin; then remove it from the heat, and stir in the tincture; lastly, add the essential oils.

II. Yellow rosin 1 lb.; gum benzoin (bright) 4 oz.; best liquid styrax 2 oz.; essence of lemons 3 oz.; oil of rosemary 2 oz.; oils of caraways and cassia, each, 1 oz. *Proc.* Keep the rosin melted by a gentle heat for 15 minutes; then remove the heat, and add the benzoin, previously powdered and rubbed up with an equal weight of tincture of benzoin, and when thoroughly incorporated add the rest; reduce it to a proper consistence with spirit of wine, and strain through flannel.

III. Balsam of Canada 16 oz.; gum benzoin, bright and clear, 5 oz.; oils of lemons, rosemary, and cassia, of each, ¼ oz. Powder the benzoin, and well mix it with the Canada balsam; then place the mixture in a flask, and after closing the mouth expose it to the heat of a water-bath, until the liquid will dissolve no more of the benzoin; next allow it to settle until clear and cold, and then add the essences.

BALSAM. *Syn.* BAUME, (*Fr.*) BALSAME, (*Ger.*) Balsams are semi-liquid resinous substances, having for the most part the consistence of honey. Some, however, are solid, and the greater number harden by exposure to the air and age. They are generally aromatic, soluble in alcohol, partly soluble in ether, and not at all so in water. Their usual constituents are resin and benzoic acid, mixed with a large portion of aromatic essential oil. Some of the substances falsely called balsams contain no benzoic acid, as the balsam of copaiba, &c.; and many preparations, from the presumption that they possess balsamic qualities, have also received this name.

BALSAM, ACOUSTIC. *Prep.* I. Tincture of benzoin, tincture of castor, and tincture of opium, of each, 1 oz.; essential oil of asafœtida 5 drops. Mix.

II. (BAUME'S.) Tinctures of ambergris, asafœtida, castor, and opium, of each, 1 oz.; terebinthinated balsam of sulphur and oil of rue, of each, 15 drops. Mix.

Use. In atonic deafness, 1 or 2 drops poured into the ear; or a piece of cotton wool moistened therewith, is introduced instead.

BALSAM OF AMBER. The thick oil left in the retort after rectifying oil of amber. The properties are similar to oil of amber.

BALSAM, ANODYNE, (BATE'S.) *Prep* Castile soap, in shavings, 3 oz.; camphor 2 oz.; powdered opium ½ oz.; hay saffron and oil of rosemary, of each, 1 drachm; rectified spirit 1 pint. *Proc.* Digest (with agitation) for 10 days.

II. Soft soap 1½ lb.; powdered opium and camphor, of each, ¼ lb.; oil of rosemary ½ oz.; rectified spirit 1 gallon. As above.

III. Opodeldoc 3 oz.; laudanum 1 oz.; mix. *Use.* As an anodyne and rubefacient for sprains, &c. *Dose.* 20 to 40 drops.

BALSAM, CANADA. This balsam is the product of the Canadian balsam fir, (the abies balsamea,) a tree of very common growth in Canada and the State of Maine, (U.S.) When fresh, it has the consistence of thin honey, an agreeable odor, an acid taste, and a pale yellow color, nearly white.

Pur. It should be perfectly transparent, and soluble in rectified oil of turpentine, with which it forms a beautiful glassy and colorless varnish, which is much used for preparing a semi-transparent copying-paper. A factitious kind is sold, but is wholly deficient of some of the properties of the genuine balsam.

BALSAM, CANADA (FACTITIOUS.) *Prep.* Dissolve 3 lb. of clear yellow resin in 1 gallon of oil of turpentine; then add ½ pint of pale linseed oil, and ¼ oz. each of essence of lemon and oil of rosemary.

BALSAM OF COPAIBA. The oleoresinous juice of the copaifera officinalis.

Pur. As this substance is frequently adulterated, and sometimes a factitious article is sold instead, it becomes important to be able to ascertain its purity.

1. The Ed. Ph. states that it should be "transparent, free of turpentine odor when heated, soluble in 2 parts of alcohol, and dissolve one fourth

of its weight of carbonate of magnesia when heated, and continue translucent."

2. Place a drop of the balsam on a piece of unsized paper, and heat it until all the essential oil be expelled; it should then form a semi-transparent *well-defined spot;* but if the balsam has been adulterated with a fat oil, it will be surrounded by an oily areola. (Chevallier.)

3. Shaken with liquid ammonia, sp. gr. ·965, it becomes clear and transparent in a few moments. (Planche.)

4. 2½ parts of balsam with 1 of liquor of ammonia, form a transparent mixture, which may be heated to 212° without becoming opaque. (Vigne.)

5. Boiled with 50 times its weight of water for 1 hour, it should lose at least half its weight. (Vigne.)

6. Two samples of balsam from Para, which were considered to have been purposely adulterated with rancid oil of almonds, dissolved well in alcohol, but combined badly with magnesia and ammonia. Direct experiments showed that pure copaiba balsam may be adulterated with 50 per cent. of a fat oil (nut oil, almond oil) without its ceasing to give a clear solution in 2 parts of alcohol. Only after 12 to 15 hours does the oil separate. Excess of alcohol separates the oil in all cases. It is evident, therefore, that under certain circumstances an unadulterated balsam may be insoluble or of difficult solution in alcohol; an adulterated one, on the contrary, may be soluble. The best test for detecting the fat oils would be alcohol to which some caustic potash has been added. (Journ. de Pharm., 1842, p. 52.)

Use. Balsam of copaiba is considered detersive, vulnerary, diuretic, and astringent; and appears to possess a sort of specific power over diseases of the mucous membranes of the urino-genital organs. *Dose.* 20 to 60 drops on sugar, or floating on water, to which 30 or 40 drops of elixir of vitriol has been added. It may be taken 3 or 4 times daily, if the stomach will bear it. A few drops of sweet spirits of nitre and laudanum are a good addition to allay the nausea. It is also given in the form of sirup, mixture, pills, and clyster.

Remarks. Numerous preparations of this article are continually being puffed off by certain advertising druggists; as "*soluble copaiba,*" "*specific solution,*" "*salt of copaiba,*" &c.; but *none* appear to possess equal activity and certainty to the natural balsam. As the whole virtue of copaiba as a medicine depends upon the essential oil it contains, the value of any of these preparations may be estimated by the quantity of that article which is found in them. In the case of the first two articles above mentioned, the quantity is *very small indeed,* and in the latter it is *wholly deficient.* Hence the large doses of those articles that may be taken with impunity, as far as their balsamic properties go, always, of course, excepting the danger of burning a hole through the coats of the stomach with the large quantity of caustic potassa which they usually contain.

BALSAM COPAIBA, ENEMA OF. (VELPEAU.) *Prep.* Balsam of copaiba ¼ oz.; yelk of 1 egg; distilled water 8 oz. Make an emulsion, and add 20 to 30 drops of laudanum.

BALSAM OF COPAIBA, FACTITIOUS. *Prep.* Powdered gum benzoin 4 oz.; castor oil 1 gallon; yellow rosin 3 lbs.; balsam of Canada 2 lbs.; oil of juniper 2 oz.; oil of savine 1 oz.; essences of orange and lemon, of each ½ oz. *Proc.* Melt the rosin, then add a little of the castor oil and the powdered benzoin, and withdraw the heat; when well mixed add the remainder of the castor oil, and when nearly cold the essences; mix well, and filter through a Canton flannel bag, adding a little coarsely-powdered charcoal.

II. Balsam of Canada 8 lbs.; yellow rosin 2 lbs.; castor oil 3 lbs.; oil of juniper ½ oz.; essential oil of almonds 15 drops; oil of savine 20 drops. As above.

III. Balsam of Canada 9 lbs.; yellow rosin 1 lb.; Venice turpentine 2 lbs.; oils of rosemary, juniper, and savine, 1 drachm each; essential oil of almonds 15 drops.

IV. Balsam of Canada 3 lbs.; Venice turpentine 1 lb.; oils of fennel, juniper, and savine, of each q. s.

Remarks. The above compounds may easily be distinguished from the genuine balsam, by any one acquainted with the characteristics of the latter.

BALSAM OF COPAIBA, REDUCED. Balsam of copaiba 4 lbs.; castor oil 3 lbs. Mix.

II. Balsam of copaiba 7 lbs.; castor oil 4 lbs.; yellow rosin 2 lbs.

III. Equal parts of balsam of copaiba and balsam of Canada mixed together.

IV. To the last add 2 lbs. of Venice turpentine.

V. Balsams of Canada and copaiba, and nut or castor oil, equal parts.

VI. Copaiba 7 lbs.; nut oil 3 lbs.; yellow rosin 2 lbs.; balsam of Canada 1 lb.

Remarks. The above are the forms for the reduction of copaiba balsam, that have from time to time been circulated in the drug trade. For the mode of distinguishing such compounds from the pure balsam, see BALSAM OF COPAIBA.

BALSAM OF COPAIBA, RESIN OF. The residuum left from the process of distilling the oil of copaiba from the balsam. (See OILS, OIL OF COPAIBA.) *Prop., Use, &c.* It consists principally of copaibic acid. It has been recommended for gonorrhœa, but appears to be nearly inert. I once foolishly swallowed, out of bravado, nearly ½ oz. of this resin, without experiencing any sensible effects in consequence.

BALSAM OF COPAIBA, SIRUP OF. *Prep* Rub 4 oz. of copaiba with 32 grs. of calcined magnesia, 64 drops of oil of peppermint, and a little simple sirup; when thoroughly mixed, add enough of the latter to make up the whole quantity to 62 oz.

BALSAM, GODBOLD'S VEGETABLE. *Prep.* Lump sugar 1 lb.; vinegar ½ pint; garlic ½ oz.; tincture of tolu 1 teaspoonful; rectified spirit 3 oz. *Proc.* Steep the garlic in the vinegar for 3 or 4 days, then strain off the clear and dissolve the sugar therein, after which add the other ingredients and shake them well together.

BALSAM, GREEN. *Prep.* Linseed oil 8 oz.; gum elemi 2 oz.; verdigris powdered ½ oz. *Proc.* Melt together and strain. *Use.* The same as green oil.

BALSAM OF GUAIACUM. *Prep.* Gum

guaiacum in coarse powder 16 oz.; balsam of Peru ½ oz.; rectified spirit 1 quart. *Proc.* Macerate for 10 days, frequently shaking the mixture.

Use. As a diaphoretic. *Dose.* 30 to 60 drops. Externally antisuppurative.

BALSAM OF HONEY. *Prep.* I. Balsam of tolu 2 oz.; gum storax and powdered opium, of each ½ oz.; honey 8 oz.; rectified spirit 1 quart. *Proc.* Mix well together, and agitate occasionally for 3 or 4 days, then decant the clear and filter the residuum. *Use.* As a pectoral, in tickling coughs. *Dose.* 1 to 2 teaspoonfuls.

II. (*Hill's.*) *a.* Balsam of tolu 1 lb.; honey 2 lbs.; rectified spirit 1 gallon. Dissolve.

b. Balsam of tolu 1 oz.; styrax 1 drachm; opium 2 drachms; honey ¼ lb.; rectified spirit 1 pint, as above. *Dose.* Half to a whole teaspoonful. As a pectoral in coughs and colds.

BALSAM OF LEAD. *Prep.* Sugar of lead 2 oz.; oil of turpentine 1 pint. *Proc.* Heat them together for half an hour, and then pour off the clear. *Use.* As a cooling external application.

BALSAM, LOCATELLE'S. *Prep.* I. Yellow rosin, olive oil, and Venice turpentine, of each 1 lb.; shavings of red Sanders wood 1 oz. *Proc.* Boil to the consistence of a thin ointment, and strain.

II. Yellow wax 4 oz.; olive oil and Venice turpentine, of each 1 lb.; alkanet root 2 oz.; as last.

Use. As a pectoral in coughs and colds. *Dose.* ½ to 1 teaspoonful mixed with the same quantity of conserve of roses.

BALSAM, PECTORAL. *Prep.* Tincture of tolu, and compound tincture of benzoin, of each 2 oz.; rectified spirit 4 oz. Mix. *Use.* As a pectoral in coughs and colds. *Dose.* A teaspoonful.

BALSAM OF PERU. *Prep. and Source.* Genuine balsam of Peru is obtained by boiling the bark and branches of the myrospermum peruiferum in water. It should possess the following characteristics:

Pur. and Tests. I. Balsam of Peru should have a consistence and appearance resembling treacle, and an aromatic odor between that of benzoin and vanilla. II. It should be entirely soluble in alcohol. III. It should undergo no diminution in volume when agitated with water. IV. 1000 parts of the balsam should saturate exactly 75 grains of pure crystallized carbonate of soda. V. Its sp. gr. should not be less than 1·150, nor more than 1·160.

Remarks. Like most other costly articles, it is both imitated and adulterated. The following are the formulæ adopted for this purpose, but the articles so produced will not answer to the above tests.

BALSAM OF PERU, FACTITIOUS. *Prep.* Balsam of tolu 1 lb.; gum benzoin 3 lbs.; liquid storax 1 oz.; rectified spirit q. s. *Proc.* The gum benzoin in coarse powder is dissolved in a little of the spirit, and then mixed up with the balsam of tolu and storax, adding as much spirit as is necessary to reduce it to a proper consistence.

BALSAM OF PERU, REDUCED. *Prep.* Balsam of Peru 3 lbs.; balsam of tolu 2 lbs.; rectified spirit enough to reduce it to a proper consistence. As above.

II. Balsam of Peru 3 lbs.; gum benzoin (dissolved in the least quantity of spirit possible) 1 lb. As above.

BALSAM, RIGA. *Syn.* Baume de Carpathes. (*Fr.*) Balsamum Libani. (*Lat.*) True Riga balsam is a pellucid white fluid, obtained from the shoots of the pinus cembra. It smells and tastes strongly of oil of juniper, and like that article is powerfully diuretic and vulnerary. The bottoms of oil of juniper thinned with spirit are generally sold for it. The spiritus turionum pini is also commonly called Riga balsam.

BALSAM, RIGA. *Syn.* Spiritus Turionum Pini. *Prep.* I. Young shoots of Scotch fir (collected in March) 2 lbs.; rectified spirit and water, of each 5 pints. *Proc.* Bruise the fir-shoots and macerate in the spirit and water for 3 or 4 days, then distil 1 gallon.

II. (*Extemporaneous.*) Mix together, rectified spirit 8 oz.; oil of juniper and compound tincture of benzoin, of each 1 oz.; agitate well and filter. *Prop., Use, &c.* Stimulant and diuretic; also used for sprains and bruises.

BALSAM OF SULPHUR. *Syn.* Oil of Sulphur. Sulphureted Oil. *Prep.* I. Flowers of sulphur 1 lb.; olive oil 8 lbs. *Proc.* Heat them together in a large iron pot, and stir until they combine. (P. E.)

II. Flowers of sulphur 1 lb.; linseed oil 1 gallon.

BALSAM OF SULPHUR, ANISATED. *Prep.* I. Dissolve 1 oz. of flowers of sulphur in 4 oz. of oil of aniseed.

II. Balsam of sulphur 12 oz.; oil of aniseed 4 oz. Mix.

Use, Dose, &c. Balsam of sulphur is said to possess expectorant and diaphoretic qualities, and has been given in doses of 40 to 50 drops, in diseases of the lungs, and used externally as an application to foul ulcers. Its disagreeable taste and smell have, however, almost precluded its use. The last two formulæ are pectoral, in doses of 10 to 30 drops.

BALSAM, THIBAULT'S. *Prep.* Myrrh, aloes, and dragon's blood, of each 1 drachm; flowers of Saint John's wort 1 handful; spirit of wine ½ a pint; Canada balsam ½ oz. *Proc.* Digest the flowers in the spirit for 3 days, then express the liquor and dissolve the other ingredients therein. *Use.* To heal cuts and wounds, and to stop bleeding Internally diuretic, in doses of 1 to 2 teaspoonfuls, given in gonorrhœa.

BALSAM OF TOLU. This substance is obtained from the myrospermum toluiferum, and when fresh, is a soft, translucent, tenacious, and resinous-looking mass, of a reddish or yellowish brown color, a fragrant odor, and a sweetish taste. It is *perfectly* soluble in alcohol, forming a *transparent* solution. By exposure to the air it becomes hard and brittle. It is frequently adulterated, in which case it has a *weaker smell*, is *less soluble in alcohol*, and the *tincture formed with that fluid is opaque*.

BALSAM OF TOLU, FACTITIOUS. *Prep.* Orange shellac and gum benzoin, of each 1 lb. in coarse powder; dissolve in rectified spirit 5 lbs., (in a close vessel;) filter and distil off the spirit until the residuum has a proper consistence, then add a few drops of the oils of cassia and nutmeg, dissolved in a little essence of vanilla.

BALSAM OF TOLU, (REDUCED.) I. Balsam of tolu 1 lb.; mix it by a gentle heat in a close vessel with 1½ lb. of the brightest and clearest pieces of gum benzoin reduced to a coarse powder,

and soften with a little tincture of vanilla and spirit of wine.

II. Equal parts of balsam of tolu, benzoin, orange shellac, and spirit of wine, mixed together by a gentle heat, and flavored with a little essence of storax and essence of vanilla.

BALSAM OF TURPENTINE. *Prep.* Melt by a gentle heat black rosin 1 lb.; remove the vessel from the fire and add oil of turpentine 1 pint.

BAMBOO, ENGLISH. This is a sort of pickle prepared from the young shoots of elder in spring. *Prep.* The outer skin is peeled off, and they are immersed in salt water for 12 or 14 hours, then boiled in vinegar for a few seconds; they are next put into a jar with a little white pepper, ginger, mace, and pimento, and vinegar (boiling hot) poured over them; the jar is then well covered up, and set for about 2 hours in a hot place by the fireside, where it is kept scalding until the pickle is done.

Use. For making Indian pickle, also eaten with boiled mutton. The clusters of elder flowers, just before they open, also make a beautiful pickle.

BANDANNA. This is a species of calico printing distinguished by light, or white figures or spots on a dark ground, and has been practised in India from time immemorial. Formerly bandanna handkerchiefs were wholly imported from India, but of late years those of British manufacture have entirely superseded them. The latter are not only much cheaper, but also vastly superior in quality. At the works of Messrs. Monteith and Co. at Glasgow, no less than 1600 pieces, or 19,200 yards of cotton, are converted into bandannas in the short space of 10 hours, by the labor of only 4 workmen. The machinery employed for this purpose is of the most ingenious description.

(*Process of printing Bandannas.*) A series of presses are arranged furnished with lead plates, out of which the pattern is cut, the pieces of cotton, dyed (generally) of a Turkey red, are then placed in, several at a time, and the presses put in action by hydraulic machinery, by which every part of the cloth, except where the pattern has been cut out of the lead plates, receives a pressure of upwards of 300 tons. A clear solution of chloride of lime is now admitted to the pattern, by properly arranged pipes, and after it has removed the color, which it does very rapidly, a stream of water is passed through the pattern, to wash off the bleaching solution, when the operation is complete. The pieces of cloth are then removed from the presses and others substituted, to undergo a similar operation.

BARBAROSSA'S PILLS. These are supposed to have been the first mercurial preparation employed in medicine. They consisted of quicksilver, rhubarb, musk, and amber.

BARCLAY'S ANTIBILIOUS PILLS. *Prep.* Colocynth 2 drachms; extract of jalap 1 drachm; almond soap 1½ drachms; gum guaiacum 3 drachms; emetic tartar 8 grs.; oils of juniper, caraway, and rosemary, of each 4 drops. *Proc.* Make the ingredients into a mass with sirup of buckthorn, and divide into 64 pills.

BAREGES WATER. *Prep.* Alum, carbonate of lime, and hard Spanish soap, of each 2 grs.; common salt 4 grs.; dried carbonate of soda 20 grs.; sulphuret of potassium 16 grs.; water 1 quart. *Proc.* Reduce the solid ingredients to powder, and boil them in the water until the fumes of sulphureted hydrogen begin to be evolved, then add enough water to make up 1 gallon. *Use.* As a medicated lotion or bath in cutaneous diseases, from the slightest eruption to the most obstinate cases of leprosy. *Remarks.* The above are the proportions for 1 gallon, but when a larger quantity of water is wanted, a proportionate weight of the materials may be dissolved in a little of the water, as above, and then added to the bath. This was the medicated warm bath used by the Emperor Napoleon.

BARIUM. The metallic base of the earth baryta, discovered by Sir H. Davy in 1808.

Prep. Make a paste with carbonate of baryta and water, and place a globule of mercury in a little hollow, formed in its surface. The whole must be then laid on a small platina tray, connected with the positive pole of a galvanic battery, of 100 double plates, while the negative wire must be inserted into the globule of mercury. An amalgam of barium is formed, which, on being heated in a vacuum, parts with its mercury and leaves the former metal pure.

Prop., &c. A dark gray colored metal, possessing little lustre, and decomposed by both air and water, absorbing oxygen, which converts it into the earth baryta.

BARIUM, BROMIDE OF. *Prep.* Boil together protobromide of iron and moist carbonate of baryta, in excess, evaporate the filtered solution and heat the residue to redness. *Remarks.* By the careful evaporation of a solution of this substance prismatic crystals may be obtained. It dissolves freely both in water and alcohol.

BARIUM, CHLORIDE OF. *Syn.* MURIATE OF BARYTA. HYDROCHLORATE OF DITTO. *Prep.* I. Carbonate of baryta ℥x; muriatic acid ½ pint; water 1 quart. *Proc.* Dilute the acid with the water, then dissolve the carbonate of baryta in it; evaporate and crystallize. (P. L.)

II. Sulphate of baryta ℔ ij; powdered charcoal ℥iv; muriatic acid q. s. *Proc.* Heat the sulphate of baryta to redness, then cool and powder; next add the charcoal, and expose the mixture in a covered crucible for three hours to a low white heat; cool and powder; lastly, dissolve in water, filter, and add muriatic acid until effervescence ceases. The solution may now be evaporated and crystallized as before. (P. E.)

Prop. Form; crystalline plates or tables, soluble in water, and fixed in the air. It communicates a greenish yellow color to flame. *Use.* Principally as a test for sulphuric acid, its solution causing a white precipitate in another, containing oil of vitriol or a sulphate. It has been given in scrofula, scirrhous cancer, skin diseases, &c. It is poisonous. Its antidotes are the same as those for baryta.

Remarks. The process of the London College is the simplest and most convenient. That of the Edinburgh requires to be conducted under a chimney, or in a strong current of air, to carry off the sulphureted hydrogen, evolved in large quantities, during the process. The form of the P. D. is similar to the Edinburgh.

BARIUM, FLUORIDE OF. *Syn.* HYDROFLUORATE OF BARYTA. A white powder formed

by digesting freshly-precipitated carbonate of baryta in hydrofluoric acid in *excess*.

BARIUM, IODIDE OF. *Syn.* Protiodide of Barium. Hydriodate of Baryta. *Prep.* I. Dissolve sulphuret of barium in water, and add iodine gradually, in *excess*, then filter and evaporate. (Phillips.)

II. Decompose an aqueous solution of iodide of iron by freshly-precipitated carbonate of baryta; filter, evaporate, and crystallize.

Use. An ointment made with 4 grs. of the iodide to 1 oz. of lard has been used in scrofula.

BARIUM, OXIDES OF. I. (Protoxide of Barium. *Syn.* Oxide of Barium. Barytes. Baryta.) When the metal, barium, is exposed to the action of either air or water this oxide is the sole product.

Prep. a. Strongly ignite the pure crystallized nitrate of baryta in a covered crucible.

b. Ignite, as before, a mixture of carbonate of baryta and charcoal in a blacklead crucible.

c. (*Hydrated.*) Precipitate a solution of either muriate or nitrate of baryta with another of caustic potassa or soda.

Prop. Obtained by the first two processes it forms a grayish white powder, having a very caustic and alkaline taste, and slaking, on the addition of water, like quicklime, but with the evolution of more heat. It then forms a bulky white powder, resembling that prepared by the last formula. It rapidly passes into the state of carbonate on exposure to air. *Use.* As a test for carbonic acid and for the formation of some salts. *Ant.* It is very poisonous. *The best antidotes* are water soured with sulphuric acid, or a solution of sulphate of soda, or sulphate of magnesia.

II. (Peroxide of Barium. *Syn.* Deutoxide of Barium.) *Prep. a.* Heat pure baryta to a dull red, and pass pure dry oxygen gas over it.

b. Heat pure baryta as above in a platina crucible, then gradually add one-fourth of its weight of chlorate of potassa. Afterwards wash off the chloride of potassium formed with cold water. The deutoxide remains as a white powder.

c. Heat nitrate of baryta to redness in an earthenware retort, having a tube attached to its nose, to convey off the liberated gases, to a trough of water, and continue the heat until nitrous fumes are no longer evolved. *Uses.* To make the oxygenized acids and peroxide of hydrogen. (Quesneville.)

BARIUM, PHOSPHURET OF. This is formed by exposing its constituents mixed together in atomic proportions, to a gentle heat in a glass tube.

BARIUM, SULPHURET OF. *Prep.* Mix together equal parts of sulphate of baryta and wheat flour or charcoal, and expose the mixture to a full white heat in a covered crucible. When cold dissolve in water, filter, evaporate, and crystallize. *Prop.* Decomposed by exposure in solution to the air. *Use.* To form baryta and its salts and in organic analysis.

BARK, BRITISH. *Syn.* Oak Bark. The bark of the young branches of the oak has been proposed for the more expensive productions of South America. The leaves also contain a large quantity of astringent matter. Mr. Stuart, who first brought oak bark into notice, says that it is a certain remedy for scurvy.

BARLEY. *Qual.* Next to wheat, barley may be considered the most valuable grain to man, both for the purposes of food and for forming several beverages in general consumption. (Malt liquors, &c.) It forms good wholesome bread, especially for persons who otherwise live luxuriously, but for those who live abstemiously wheaten bread is preferable.

BARLEY, CULTIVATION OF. After wheat, barley may be considered the most important grain crop, especially in light and sharp soils, but it "is a tender grain, and easily hurt in any of the stages of its growth, particularly at seed-time; a heavy shower of rain will then almost ruin a crop on the best-prepared land; and in all the after-processes, greater pains and attention are required to ensure success than in the case of other grains. The harvest process is difficult, and often attended with danger; even the thrashing of it is not easily executed with machines, because the awn generally adheres to the grain, and renders separation from the straw a troublesome task. Barley, in fact, is raised at a greater expense than wheat, and generally speaking is a more hazardous crop. Except upon rich and genial soils, where climate will allow wheat to be perfectly reared, it ought not to be cultivated.

"Barley may be divided into two sorts, early and late; to which may be added a bastard variety, called bear or bigg, which affords similar nutriment or substance, though of inferior quality. Early barley, under various names, was formerly sown in Britain, upon lands that had been previously summer fallowed, or were in high condition; but this mode of culture being in a great measure renounced, the common sort, which admits of being sown either early or late, is now generally used.

"The most proper seed-season is any time in April, though we have seen good crops produced, the seed of which was sown at a much later period."

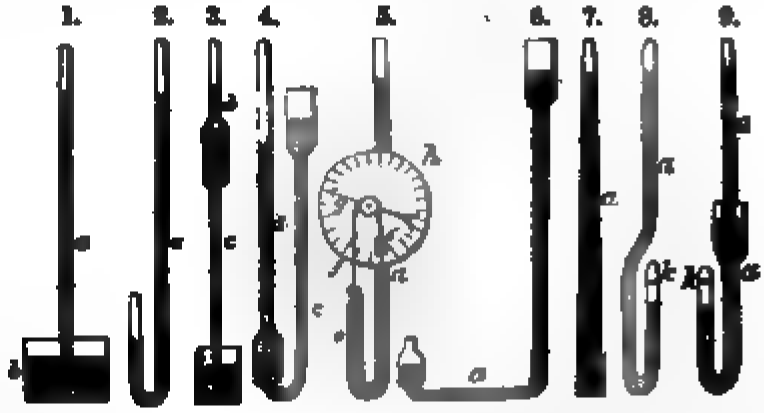
Barley is generally sown after turnips and frequently after peas and beans, but seldom after wheat or oats. The quantity of seed varies with the quality of the soil. Upon very rich land eight pecks per acre are commonly sown, and frequently ten or twelve, whilst upon poor lands a larger quantity is sometimes given. Enough seed should be sown to ensure a full crop without offsets, which are always produced if too little seed is used.

The harvesting of barley requires much care even in good seasons, while, in bad ones, it is very difficult to save it. It must be cut before the straw gets brittle, and must be suffered to remain in the field until the grain is hardened, and the straw sufficiently dry. If stacked too soon it is apt to heat. A good way to prevent this is to form an opening through the stack from top to bottom. This opening is generally made by placing a large bundle of straw in the centre of the stack, when the building commences, and, in proportion as it rises, the straw is drawn upward, leaving a hollow behind, which, if one or two openings are left in the side of the stack near the bottom, ensures so complete a circulation of air as not only to prevent heating, but to preserve the grain from becoming musty.

BARNS AND OUTHOUSES FROM MITES AND WEEVILS, TO FREE. (*German method.*) Let the walls and rafters, above and below, of such granaries be covered completely

with quicklime, slaked in water, in which trefoil, wormwood, and hyssop, or nux vomica have been boiled. This composition should be applied as hot as possible. "A farmer who had his granaries empty in June last, collected quantities of the largest sized ants in sacks, and scattered them about the place infested with weevils. The ants immediately fell upon and devoured them all."

BAROMETER. (From βαρος weight and μετρον, measure.) An instrument for measuring the weight and pressure of the atmosphere, commonly termed a weather-glass. This instrument is made of various shapes, but the principle of its construction is the same in each, and consists of a column of mercury, supported in vacuo, in a glass tube, by the pressure of the atmosphere on its surface. The following engravings represent the principal varieties. The several shapes have arisen from the attempts which have been made from time to time to improve this instrument, either by increasing its range or portability. None, however, equal the old forms proposed by Torricelli, and represented by the figures 1 and 2. The same letters apply to a similar portion of each figure; the references at foot will therefore sufficiently explain the peculiarities of their construction.



1. Torricelli's cistern barometer.
2. ———— syphon ditto.
3. Huygen's barometer.
4. ———— modified.
5. Wheel barometer.
6. Bernouilli's syphon ditto.
7. Amiston's conical ditto.
8. Gay Lussac's ditto.
9. Ditto, modified by M. Bunten

a, Tube containing a column of mercury.
b, Mercurial cistern.
c, A column of mercury supporting another of water, d.
e e, Weights, one of which floats on the surface of the mercury, and by means of the cord f moves the index g.
h, Graduated dial.
k, Capillary hole drilled laterally to admit air.

The wheel barometer (fig. 5) is the one most commonly used, especially as a weather-glass, but it is not to be depended on, as it neither indicates the absolute height of the mercurial column, nor its variations with sufficient accuracy for any philosophical purpose. Even as a weather-glass it is the worst of all the common forms of the barometer. For travelling the last is perhaps the most unexceptionable.

The Construction of a Barometer may be divided into five operations, in each of which the utmost skill and care are required. The materials must be of the *best quality*. Not only must the mercury be perfectly pure and free from air, but the tube must be quite dry and clean, and its inner surface must be smooth and regular.

1. *The tubes* for barometers should be hermetically sealed immediately after their manufacture at the glasshouse, and kept in this state until they are wanted for filling. By this plan they may be kept clean for any length of time, whereas if they are left with one end open they become sullied with dust and smoke, which, on account of the smallness of their diameters, can never be perfectly removed. When wanted for use they may be opened with a file, after which care must be taken not to breathe into them, and washing them out with spirit of wine, &c., especially avoided. When cleaning is absolutely necessary, it should be done by means of a clean, dry linen rag, and a piece of wire, observing not to let the end of the wire scratch the glass, as, if it does, such tubes will generally be found broken, if laid aside for a short time, or, what is worse, they will break during the process of filling them. The best tubes are perfectly cylindrical, 33 inches in length, and the diameter of their bore never less than 2 to 2½ lines, as the capillary attraction and friction increases in an inverse ratio to the capacity of the tube. The thickness of the glass should not greatly exceed half a line.

2. *The mercury* must be perfectly pure, which should be ascertained before using it, as, if it be adulterated with common metals, as is frequently the case, its fluidity is lessened, and its tendency to oxidize increased. When it cannot be got unadulterated it should be rectified in an iron retort; or pure cinnabar, mixed with half its weight of iron filings, may be treated in the same way, when pure mercury will distil over. (See Mercury.)

3. *Filling the tube* is performed by pouring the mercury into it, having previously boiled it in a porcelain or iron vessel, to expel the air. The tube is then exposed to a gradually increasing heat over a chafing-dish of charcoal until the mercury boils, and all the air in the tube is extricated; it is now allowed to cool and again filled up with mercury, and the exposure over the chafing-dish repeated; when again perfectly cool it may be filled up with a little freshly-boiled mercury, and is then ready for fixing in its frame.

4. *The tube filled as above must next be placed in its frame*, for which purpose the open end is perfectly stopped, and it is inverted into a small trough of prepared mercury; or if it be of the syphon kind, simply inverted and fixed in its frame.

5. *The graduated scale* has now to be adjusted to the tube. This is usually done by means of a tangent screw, which permits the scale to be raised or lowered, until its zero exactly corresponds to the lower surface of the mercury; but in many cases

the cistern is raised or lowered by means of screws arranged for that purpose. The best mode of obtaining an exact adjustment of the surface of the mercury to the zero of the tube, is that adopted by the celebrated French artist, Fortin. An ivory needle is attached to the scale pointing downwards, its point being exactly on a level with the zero of the scale. The image of the needle is clearly reflected from the surface of the mercury in the cistern, and either the scale or cistern is raised or lowered, until the point of the needle and its image exactly coincide.

Use. This instrument is employed for ascertaining the amount of atmospherical refraction in astronomical calculations, in measuring altitudes and in prognosticating the weather. For the latter purpose, on land, it frequently proves a false prophet, but at sea, (according to Dr. Arnot,) the case is widely different, and its monitions are worthy of attention. (Elem. Nat. Phil. i. 353.)

Remarks. The above is a brief outline of the method of constructing barometers, and in proportion to the skill therein exercised will be the accuracy of the instrument. However cleverly this may have been performed, it is nevertheless found that these instruments gradually suffer deterioration from the external air insinuating itself between the mercury and the glass tube, thus lessening the perfection of the vacuum. Various plans have been proposed to remedy this inconvenience and source of error. Professor Daniels lines the bottom of the tube with platinum to the extent of about ½ of an inch; this has proved quite sufficient. Dr. Ure uses platinum foil for the same purpose. It is usual, as I have above described, to boil the metal after its introduction into the glass tube, but some persons disapprove of this practice in consequence of the mercury absorbing a little oxygen during the process, and instead thereof, they strongly heat the glass tube and pour in the mercury very hot.

BAROMETER, PORTABLE, (SIMPLE.) This instrument consists in general of a tube of the usual length, passing through the upper parts of a wooden cistern, to which it is glued, and the bottom of which is made of leather. The tube being filled with mercury, which has been previously well purged of air, and placed in a proper position, the superfluous mercury descends into the cistern, and assumes a level in the tube corresponding with the weight of the external air. The surface of the mercury in the cistern is adjusted to the same level by a screw, which presses more or less against the flexible leather at the bottom, and raises or depresses it at pleasure. From the line of this level, which is called zero, the scale commences, and is reckoned upwards to the height of about 32 inches; the actual divisions of the scale begin at about 15 inches.

Remarks. The most accurate portable barometers are those of Gay Lussac and Bunten, (Figures 8, 9.) When set on universal joints and well balanced, they are the most perfect instruments for ships that have been yet constructed.

BAROMETER, TROUGHTON'S MARINE. The tube of this instrument consists of two parts, joined together about 5 inches below the top; the bore in the upper part being about $\frac{4}{10}$ of an inch, and in the lower part only $\frac{2}{100}$. By this construction, partly from the difference of the bores, and partly from the greater friction in the lower end, the motion of the mercury is so much retarded, that any impulse given by the ship, having a tendency to raise it, will scarcely have produced a sensible effect, before an opposite impulse will be given, having a tendency to depress it. To counteract more effectually the effects of the ship's motions, the instrument is suspended in gimbals.

BAROMETER, THE VIAL. *Prep.* Take a common vial and cut off the rim and part of the neck, by means of a piece of cord passed round it, and moved rapidly to and fro, in a sawing direction; the one end being held in the left hand and the other fastened to any convenient object, while the right hand holds and moves the vial; when heated, dip it suddenly into cold water, and the part will crack off; or separate it with a file. Then nearly fill the vial with clean water, place your finger on the mouth and invert it; withdraw your finger and suspend it in this position with a piece of twine. In dry weather the under surface of the water will be level with the neck of the bottle, or even concave; in damp weather, on the contrary, a drop will appear at the mouth and continue until it falls, and is then followed by another in the same way.

Barometrical corrections. Cistern barometers formed of tubes of very small diameters, require what is called "correction for capillarity."

The following Table is taken from the "Encyclopædia Britannica."

Diam. of Tube.	Depression.
Inches.	Inches
0·10	0·1403
0·15	0·0863
0·20	0·0581
0·25	0·0407
0·30	0·0292
0·35	0·0211
0·40	0·0153
0·45	0·0112
0·50	0·0083
0·60	0·0044
0·70	0·0023
0·80	0·0012

Remarks. It will be seen, that as the tube increases in diameter, so the depression of the mercury lessens. Syphon barometers that have each of their legs of equal size, require no correction, as the depression is equal at both ends. A correction is also made for temperature in nice observations, but this is of too scientific a nature to be entered into in the present work.

BAROMETRICAL RULES FOR PROGNOSTICATING THE WEATHER.

1. After a continuance of dry weather, if the barometer begins to fall slowly and steadily, rain will certainly ensue; but if the fine weather has been of long duration, the mercury may fall for 2 or 3 days, before any perceptible change takes place, and the longer time that elapses before rain comes, the longer the wet weather is likely to last.

2. Conversely, if, after a great deal of wet weather, with the barometer below its mean

height, the mercury begins to rise steadily and slowly, fine weather will come, though 2 or 3 wet days may first elapse; and the fine weather will be the more permanent, in proportion to the length of time that passes before the perceptible change takes place.

3 On either of the two foregoing suppositions, if the change immediately ensues on the motion of the mercury, the change will not be permanent.

4. If the barometer rises slowly and steadily for two days together, or more, fine weather will come, though for those two days it may rain incessantly, and the reverse; but if the barometer rises for two days or more during rain, and then, on the appearance of fine weather, begins to fall again, the fine weather will be very transient, and *vice versa*.

5. A sudden fall of the barometer in spring or autumn indicates wind; in summer, during very hot weather, a thunder-storm may be expected; in winter a sudden fall after frost of some continuance, indicates a change of wind with thaw and rain; but in a continued frost a rise of the mercury indicates approaching snow.

6. No rapid fluctuations of the barometer are to be interpreted as indicating either dry or wet weather of any continuance; it is only the slow, steady, and continued rise or fall, that is to be attended to in this respect.

7. A rise of the mercury late in the autumn, after a long continuance of wet and windy weather, generally indicates a change of wind to the northern quarters, and the approach of frost.

BARYTA. *Syn.* PROTOXIDE OF BARIUM. OXIDE OF DITTO. (See BARIUM.)

BARYTA, SALTS OF. *Prep.* All the soluble salts of baryta may be made by solution of its carbonate or hydrate in the dilute acids, and the insoluble salts, generally, by the double decomposition of its muriate, by a soluble salt of the acid.

BARYTA, TESTS FOR, AND ITS SALTS. I. This earth forms an alkaline solution with water. II. Baryta in solution, and all its salts, give a white precipitate in alkaline carbonates and sulphates, and sulphuric acid; the last two being insoluble in both acid and alkaline menstrua.

BARYTA, ALLOXANATE OF. *Prep.* Add barytic water to an aqueous solution of alloxan, heated to 140°, until the precipitate formed, ceases to be redissolved on stirring; then cool and collect the crystals, and repeat the process of adding barytic water to the mother liquor, which will thus furnish several crops of crystals. *Use.* To form some salts.

BARYTIN. A new vegetable base discovered by Simon, in the rhizomes of white hellebore. It is precipitated from its solutions by sulphuric acid and the sulphates, like baryta, hence the name; and this property affords a means for its separation.

BASE, (IN CHEMISTRY.) A term applied to metallic oxides, (from their forming salts with acids,) and to the principal constituent of a compound. Thus: *soda* is called the base of *sulphate of soda*, (glauber salts;) *quinine* the base of *disulphate of quinine*, *&c.* Forms will be found in this book for the preparation of the principal bases, as well as their salts.

BASILICON, BLACK. *Prep.* Yellow wax 1 lb.; black rosin and olive oil, of each 2 lbs. *Proc.* Melt together and strain through a piece of canvass. *Remarks.* This old preparation is similar to the resin cerate of the London Pharm., with the exception of containing *black* instead of *yellow* rosin. Linseed oil, used instead of olive oil, comes cheaper, and is preferred by many persons.

BASSORIN. *Syn.* INSOLUBLE GUM. The insoluble portion of gum tragacanth, &c., after the soluble part has been removed with water. *Prep.* It is best prepared by soaking gum bassora in a large quantity of hot water, and filtering off the clear portion.

BATEMAN'S PECTORAL DROPS. *Prep.* Paregoric 10 oz.; tincture of castor 4 oz.; laudanum 1 oz.; tincture of saffron or cochineal ½ oz.; oil of aniseed 15 drops. Mix. *Dose.* A teaspoonful or more in coughs and colds.

BATEMAN'S ITCH OINTMENT. *Prep.* Carbonate of potassa 1 oz.; red sulphuret of mercury ½ oz.; hog's lard and flowers of sulphur, of each 22 oz.; bergamotte 60 drops; rose-water 2 oz. *Proc.* Mix the potassa and powders with a little of the lard, and rub them well together, then add the remainder of the lard, previously softened by heat, and afterwards the rose-water gently warmed; stir until cold.

BATHS, BATHING. *General Remarks.* The practice of bathing is not only an act of cleanliness, but is eminently conducive to health. The delicate pores of the skin soon become choked by the solid matter of the perspiration and the accumulation of dirt, and require frequent ablution with water, to preserve their natural functions in a state of activity. The mere wearing of flannel and washing the more exposed parts of the body, and the daily use of clean linen, is but an imperfect attempt at cleanliness, without being accompanied by entire submersion of the body in water. The phlegmatic Englishman, unlike his lively French neighbor, seems perfectly incredulous on this point, and would sooner spend his sixpence or his shilling in a glass of grog, or a ride to Greenwich, than in the healthy recreation of the bath.

Bathing is not only conducive to cleanliness, but to both the physical and mental health. The body cannot be in a state of *lively health*, while the proper offices of the skin are interfered with, any more than would be the case with either of the other excretory organs, placed in a like condition. Nor can the mind, dependent as it is on the organization of the body, escape unharmed, when the animal functions are imperfectly performed. Intellectual and moral vigor are universally promoted by the imperceptible yet controlling influence of the physical system, and he who would increase the former, cannot go on a safer method than that which tends to preserve or improve the health.

"On the continent, '*Maisons des Bains*,' or bathing-houses, are almost as numerous as the chemists and druggists are in this country. The inference necessarily is, that bathing in France is as much patronized as physic is in England. The French need the latter less, because they live more temperately, are less ground down to think and work; and because they perform general personal ablution (to the benefit of one of the most important functions of life, namely, free perspiration) with as much zeal as though it were a re-

ligious duty. The inducement to such frequent use of the warm bath among our neighbors, may be fancied to be the low charges for bathing, and the little value the *Messieurs* attach to their own time. The first notion is a fallacy. Warm bathing on the continent is not cheaper in comparison with all the other necessaries or luxuries of life, viewed in connection with a foreigner's resources, than it is in England. With regard to the apparently little importance they attach to their own time, they are wise enough to discover, that life is not one jot sweeter by passing sixteen hours a day behind the desk or counter, to the exclusion of all recreation, except recreation be to count the gains of such exilement; or to indulge the hope of amassing a sufficiency to do the '*important*' at the close of a wearied life, when and which the infirmities of age forbid to enjoy. *A Frenchman lives, works, and enjoys himself to the last. Prince Talleyrand died in armor; his life was a bouquet in which all but the sweetest flowers were excluded.* A Frenchman takes the bath for the mental and bodily gratification it affords; he can appreciate the luxury of it, while at the same time he is sensible of its healthfulness. An Englishman is such a stiffnecked fellow, that in most things, he will only do that which pleases him best, and his standard of pleasure is estimated by that which adds most to his hoard, and which gives the greatest amount of satisfaction to the inward man. Advise him to take a warm bath; the answer is, he cannot spare the time, and he hates the bother of uncravating, &c. The waste of the one and the trouble of the other add not to his income, whatever they may to his health. The roast beef, the brandied wines, and the London-brewed are his stomach's deities, the minor godships being blue pills and black draughts. The latter are indispensable attendants upon the former, to temper down Mr. Bull, lest he become a giant in noses and carbuncles. *A Frenchman knows no ill but what pleasure denies; he rarely has dyspepsia, gout, rheumatism, or fevers. Half his life is spent in Elysium,—half ours in* PURGATORY. Indigestion, headaches, restless nights—the *blues* when awake, and the *terribles* when asleep—fall to the lot of the mind-absorbed and grossly-fed Londoner, while our lively Parisian, with his light meal and still more lightsome body, finds trouble only in broken limbs, or positive starvation."

The warm bath, especially, is one of the most valuable, but most neglected remedies which we possess. It is generally imagined by Englishmen, that bathing is but little fitted for their country, owing to the changefulness of the climate, and that to attempt to place a sick man in a bath in any other than the mildest weather, would be to subject him to all the horrors of "*sniffling, sneezing, coughing, and relapse.*" But that such results of bathing have no existence beyond the minds of the fearful, ignorant, and prejudiced, must be acknowledged by every candid person. Even the cold bath, as in the treatment termed "hydropathy," is beneficial when applied with judgment; and it is only when common discretion is not exercised, that bathing under any shape ever proves injurious.

Some persons are very susceptible of taking cold, and are themselves "*living barometers;*" but even to them warm bathing would prove advantageous. One half of the rheumatic twinges, swollen limbs, and cramped joints that occur in such persons, would give way before proper perseverance and confidence in this remedy.

Whenever in delicate persons the cold bath is deemed proper, the warm, tepid, and cool bath may be used as a preparative, and when the former is at length adopted, it should be at first only for one or two minutes at a time, gradually increased to a quarter of an hour or twenty minutes; care being taken never to remain immersed sufficiently long to induce a sensation of cold on coming out. A healthy reaction should follow the bath, and a pleasing glow of warmth should diffuse itself over the surface of the body. If this be not the case, the bath has either been indulged in too long, or been injudiciously taken. When any symptoms appear that contra-indicate the use of the cold bath, the tepid, warm, or vapor bath may be substituted, according to circumstances.

In conclusion, I may remark, that bathing, *especially in water at a temperature nearly similar to that of our bodies*, (tepid bath,) is at once one of the most cleanly and health-preserving luxuries, or, I should say, necessaries of life. The following short notice of each description of bath, is all the space that can be spared for this subject.

I. *Affusion of cold water* over the surface of the body, has been adopted with success, for arresting the progress of some fevers. In scarlatina, &c., sponging the body with tepid water, or water mixed with vinegar, has been employed instead.

II. *Air bath. a.* (*Cold.*) The mere exposure of the body in a state of nudity to the atmosphere, forms the common air bath. It has been found useful in allaying slight degrees of febrile excitement, and to act as a mild tonic, when not too long continued.

b. (*Hot.*) This consists in placing the patient in an apartment to which heated air is admitted. It is generally considered to be more stimulant than the vapor bath; it produces a powerful perspiration, and has been recommended in cholera, congestive fevers, rheumatism, scaly skin-diseases, &c.

III. *Chlorine bath.* Water holding in solution a small quantity of chlorine gas. Its action has not been much examined. I may mention here, that I have seen several cases of itch cured by two or three immersions in a warm bath, to which a little chloride of lime has been added.

IV. *Cold bath.* The temperature of this bath varies from 45° to 85°. It is considered tonic and stimulant, when not too long continued. To produce its full effects, the patient should feel a pleasant glow upon the surface of the body, immediately on coming out of the water. If a sensation of coldness or shivering follows, it should not be repeated. The duration of the immersion may vary from two minutes to a quarter of an hour, depending upon the temperature of the water, and the feelings of the bather; the latter period not being too long, *provided* swimming or violent exercise be adopted in the bath. The temperature of the water of the rivers, and on the coast of England, varies in summer from 55° to 70°.

The following hints on cold bathing may be interesting to the reader.

1. "In using the cold bath, it is of essential importance to know that there is no truth in the vulgar opinion, that it is safer to enter the water when the body is cool, and that persons heated by exercise, and beginning to perspire, should wait till they are *perfectly cooled*.

"It is a rule liable to no exception, that moderate exercise ought always to precede cold bathing; for neither *previous rest*, nor *exercise to a violent degree*, is proper on this occasion.

2. "The duration of cold bathing ought to be short, and must be determined by the bodily constitution and sensation of the individual; for healthy persons may continue in it much longer than valetudinarians. In summer it may be enjoyed for an hour, when in spring or autumn, one or two minutes will be sufficient. Under similar circumstances, cold water acts on aged and lean persons with more violence than on the young and corpulent; hence the former, even in the hottest days of summer, can seldom with safety remain in the bath longer than a quarter of an hour; while the latter are generally able to sustain its impressions for a much longer period.

3. "The head should first come in contact with the water, either by immersion, by being showered upon, or by covering it for a minute with a wet cloth, and then plunging head foremost into the water.

4. "As the immersion will be less felt when it is effected suddenly, and as it is of consequence that the first impression should be uniform over the body, the bath ought *not* to be entered slowly or timorously, but with a degree of boldness. A contrary method, in some constitutions, is dangerous, as it propels the blood from the upper to the lower parts of the body, and thus predisposes to a fit of apoplexy. For these reasons, the *shower* bath is attended with considerable advantages, because it transmits the water quickly over the whole body.

5. "The morning is the proper time for using the cold bath, unless it be in a river; in which case the afternoon, or from one to two hours before sunset, will be more eligible. On the whole, one hour after a light breakfast, or two hours before, or four after dinner, are the best periods of the day for this purpose.

6. "While the bather is in the water, he should not remain inactive, but apply brisk and general friction, and move his arms and legs, to promote the circulation of the fluids from the heart to the extremities. It is extremely imprudent to continue in the water till a second chilliness attacks the body.

7. "Immediately after leaving the bath, it is necessary that the bather should quickly wipe his body dry with a coarse dry cloth. He should not afterwards sit inactive, but if the season permit, he ought to take gentle exercise, till the usual circulation, and the customary action of the muscles, be restored.

8. "The best place for cold bathing is in the sea, or a clear river; but where neither of these can be conveniently had, the shower bath may be used.

9. "The principal advantages to be expected from cold bathing, besides the salutary exercise, are either the reduction of excessive heat, or the producing of a salutary reaction of the system. In the former, it has been found useful in several fevers. *Affusion*, however, in those cases, is most advisable, and more efficacious in reducing the morbid temperature, than immersion. But the cold affusion must not be employed in the cold stage. As soon as the hot fit is formed, the cold affusion is to be used immediately, and repeated occasionally. In the sweating stage, it is to be cautiously avoided.

"In nervous diseases, too, the cold bath has sometimes been of service.

"In gouty and rheumatic complaints, in diseases of the hip-joint, lumbago, or sciatica, after the removal of those complaints by the use of the vapor or hot bath, and in conjunction with other remedies, the alternation of the cold with the vapor bath fortifies the constitution against a return of such attacks.

10. "The best preparation for cold bathing, is to begin with a warm, then a tepid, and afterwards a cool bath; after this course the bather may in general plunge with safety into the cold bath. In most cases, a bath every second day, from the commencement of the warm bathing to the end of a fortnight, will be sufficiently frequent; afterwards the cold immersion may be continued daily."

V. *The douche* consists in the projection of a stream of cold water from a tube upon any part of the body. It is powerfully sedative, and has been long employed in inflammation of the brain. It should be used with caution, as its action is so powerful that a full inflammatory pulse frequently sinks into one almost imperceptible, in a very short space of time. It is one of the principal methods of applying cold water adopted by the hydropathists.

VI. *Medicated baths.* These consist of water holding in solution various medicinal substances; as wine-baths, milk-baths, soup-baths—these have been used to convey nourishment to the body; sulphureous baths, mercurial baths, &c., used in skin diseases, syphilis, &c.; aromatic and chalybeate baths, employed as tonics; acid baths, sometimes used to remove the effects of mercury, &c.

VII. *Nitromuriatic bath. Prep.* Mix 3 fluid ounces of muriatic acid with 2 fluid ounces of nitric acid, and 5 fluid ounces of distilled water, and add 3 ounces of the above mixture to every gallon of water in the bath. Should the bath prick the skin, a little more water may be added.

Remarks. This bath was first introduced as a remedy for liver complaints. It must be contained in a wooden vessel, and may be used as a hip, knee, or foot-bath, a knee-bath being the one generally adopted in England. The inventor, Dr. Scott, once plunged the Duke of Wellington up to his chin in a bath of this kind in India, and thus cured him of a severe hepatic affection.

VIII. *Sulphur bath. a.* The patient is placed (not including the head) in a species of box, at the bottom of which is put a piece of hot iron, on which a little sulphur is thrown, great care being taken to avoid the escape of the fumes, and the inhalation of the same by either the patient or the attendants. Another method is to dissolve a little sulphuret of potassium in the water of a common warm bath. The proportion is 1 oz. of the sul

phuret to 8 gallons of water. This form of the bath is not, however, quite as efficient as the gaseous one first described.

b. (*Dupuytren's gelatino-sulphurous bath.*) This is formed by dissolving 1 oz. of the sulphuret of potassium and 4 oz. of Flanders glue, in every 8 gallons of the water of a warm bath. It is an imitation of the celebrated waters of Barèges, the glue supplying the place of the barégine found in the latter.

Remarks. The sulphur-bath under any form is a powerful remedy in every description of skin disease. Leprosy, the most obstinate of all, has been cured by it. The common itch requires only one or two applications of the sulphur-bath to eradicate it entirely. All forms of scurf, whether on the face, head, or body, yield to its influence. Local irritation occasioned by minute pimples, or inflammatory patches of disordered skin, is speedily subdued and removed. Scrofula, and also those affections for which the warm or vapor baths have been recommended, will derive powerful assistance from the sulphur-bath.

IX. *Tepid bath.* The temperature of this bath varies from 85° to 92° Fahr., 88° being considered a medium temperature. Its action on the body is intermediate between that of the warm and cold baths, and is admirably adapted for the purposes of cleanliness, and promoting the healthy action of the skin. It is frequently employed as a preparative to cold bathing.

X. *The warm bath* has a temperature of from 92° to 100° Fahr., or about that of the human body.

Remarks. The warm bath is at once the most luxurious and effective mode of bathing, and if taken under proper restrictions, is highly conducive to health. If only on the grounds of personal cleanliness, this species of bathing has the highest claim on our attention. "The sensations attendant upon immersion in a warm bath are most delicious. Its effect is, first to increase the circulation of the blood, and to determine it to the skin; after a few minutes an agreeable and universal increase of heat is experienced; the face, and forehead generally, are soon bedewed with perspiration: a pleasing and prevailing calm is felt, mentally and physically; and after remaining in some 12 or 15 minutes, coming out and dressing, the refreshing feeling and consciousness of personal purity give rise to associations of the most happy character. The warm bath may be taken at any time during the day: it is perhaps better to employ it upon an empty stomach, or before a meal, rather than after one. The temperature should be from 98° to 100°; the time of immersion should not exceed 15 minutes. The old idea that it is relaxing, is erroneous, except where persons remain in for hours, as some people do, or where it is taken too often."

The warm bath, in a medical point of view, is especially adapted to general torpor of the system, liver and bowel complaints, hypochondriasis, hysterical affections, morbid suppressions, dry skin, nearly all cutaneous and nervous diseases, chronic rheumatism, &c. As a tonic or stimulant after excessive fatigue, great mental excitement, or physical exertion, it is unequalled, and furnishes one of the most wholesome, and at the same time luxurious sources of refreshment we are acquainted with.

XI. *The vapor-bath* consists in vapor being admitted to the apartment, and thus not only is the body immersed in it, but it is inhaled as well. It is used at different temperatures, known by the name of *tepid*, when the temperature varies from 90° to 100°; *warm*, when from 100° to 112°; and hot, from 110° to 130°; but when the vapor is not inhaled, the heat of the latter may be raised to 160°.

Remarks. The principal action of the vapor-bath is to produce a copious diaphoresis. In fact, it is the most powerful diaphoretic agent known. It is a certain specific for a cold; and in all those cases wherein warm bathing is recommended, the vapor-bath ranks highest. It constitutes the most powerful pharmaceutical remedy existent: combined with friction, or shampooing, its utility in cases requiring an additional action, as in contracted muscles, tendons, &c., is much increased; "and instances are numerous, where the lame have thrown aside their crutches, and the bed-ridden have again mixed with the world, after a few applications of this bath." "It is no uncommon thing to hear a patient start and shriek with agony before entering the bath, and to receive his congratulations and thanks on his coming out: they will oftentimes exclaim,—'*It is wonderful! I could not have believed it—I am well—I can walk—I can jump!*'"

The vapor-bath is administered in chronic rheumatism, stiff joints, long-continued indigestion, gout, lumbago, sciatica, scrofulous swellings, fever, skin diseases, &c., but should be avoided in acute inflammations, and for persons of a very full and excitable habit of body.

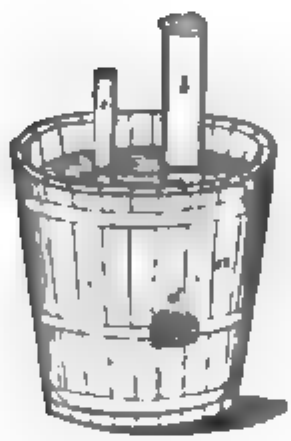
XII. *The shower-bath.* This may be regarded as a modification of the cold bath or plunge bath, and its effects are similar. The cold shower-bath is however less alarming to nervous persons, and less liable to produce cramp, than cold immersion: it may be considered as the best and safest mode of cold bathing, and is recommended in many nervous complaints.

It has also afforded relief in some cases of insanity.

Where the saving of expense is an object, or a regular shower-bath is not to be procured, a large common watering-pot filled with cold water may be used as a substitute. Let the patient sit undressed upon a stool, which may be placed in a large tub, and pour the water from the pot over the head, face, neck, shoulders, and all parts of the body, progressively down to the feet, until the whole has been thoroughly wetted.

BATHS, TO HEAT. Various methods have been proposed for this purpose, but they are for the most part expensive and unsuited to private families. The following plan, however, is an exception to the above, and will be found at once cheap and convenient.

Italian plan of warming baths. This consists in immersing in the bath a sort of U or syphon-shaped sheet iron tube, furnished with a little fire-place, near the bottom, for the purpose of burning charcoal. In the following figure is given a representation of this simple apparatus and its application.



a, Bath tub.
b, The larger arm of the warming-tube by which the charcoal is introduced, and by which the fumes fly off.
c, The smaller arm to admit air to support the combustion.
d, The fire-grate, to support the burning charcoal.

BATHS, THE SITUATION OF. This should always be, if possible, near the principal bedrooms on the same floor, for the sake of ready access to them, and in a place where plenty of good water can be procured.

BATHS, (in Chemistry.) These mostly consist of water or alkaline solutions, in which vessels are placed containing substances that it is desirous to submit to a limited degree of heat. The highest temperature that can be given to any substance contained in a vessel placed in another of boiling water, is about 205 or 206°; but by adding one-fifth of salt to the bath, a heat of 212° may be obtained. Baths of fusible metal, saturated solutions of salt, sand, and (on the large scale) steam, are also used. (See Boiling Point.)

BATH METAL. *Prep.* Melt together, under charcoal, 1 lb. of brass, with 4½ oz. of spelter.

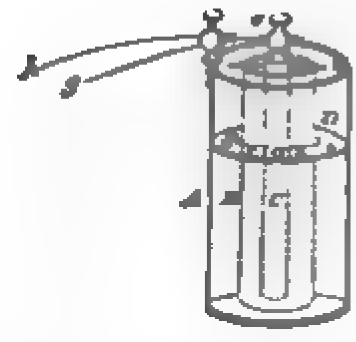
BATH PIPE. *Prep.* Powdered white sugar 1 lb.; Italian juice (dissolved in a little water) 2 oz.; powdered gum arabic 1 oz. *Proc.* Make them into a stiff mass with warm water, and roll it into the usual form.

BATTER, (in Cookery.) A mixture of flour, milk, eggs, oil, or butter, and frequently spices, beat together to a thin paste. *Use.* To cover various articles during the operation of cooking, and also to form puddings.

BATTERY, GALVANIC OR VOLTAIC. An instrument or apparatus for the production of an electrical current by chemical decomposition.

One of the most useful forms of the galvanic battery is that proposed by Professor Daniell, and commonly known by his name. Its peculiar advantages arise from its action continuing without interruption for a long time, hence the name of *constant battery* that has been applied to it. The following figure will explain its construction.

Between the membrane and the copper cylinder is poured a saturated solution of blue vitriol, and in the diaphragm or cylinder *B*, dilute sulphuric acid of the s. g. of 1·136 made with about 1 part of oil of vitriol and 7 or 8 of water. The battery is now ready to be applied to the purposes of electrotyping, for which *one* is quite sufficient; *six* of these simple batteries will form a circle of considerable power, and about 20 will produce one sufficiently strong for most experiments of demonstration and research.



A, A copper cylinder filled with a saturated solution of sulphate of copper.
B, A smaller porous cylinder or membrane, containing a mixture of 1 part of oil of vitriol and 7 of water.
C, A rod of zinc supported in the smaller cylinder by the cross-piece *i*.
D, A shelf full of small holes, for supporting crystals of sulphate of copper, to keep up the strength of the solution.
e and *f*, Screws and caps to connect the wires *g* and with the battery.
g, The positive wire.
h, The negative wire.

II *Another permanent battery* of considerable power is formed by arranging a series of cells, 2 inches in diameter, in each of which is placed a smaller cell, of 1 inch in diameter. The latter are filled with a solution of sulphuret of potassium, of the sp. gr. 1·14, and the former with nitric acid, of the sp. gr. 1·35, the pairs are then connected together with small discs of platinum foil.

III. *Professor Jacobi* has lately described a very *simple*, *cheap*, and *convenient* form of battery said to be discovered by a Russian prince, but which is, in reality, only an adaptation on the small scale, of the terraqueous battery of Mr. Bain, by which he works his telegraph. This new battery is formed by immersing a plate of zinc and another of copper, in common garden mould, placed in a flower-pot, when, on completing the circuit, a powerful current of electricity is produced. All that is necessary to keep up the action of the battery is to moisten the earth with a little water. The plates should be placed equidistant from each other, and the sides of the pot. The professor has had a battery of twenty of them at work for a month without their activity being apparently diminished.

BEANS. *Qual.* A wholesome esculent, when eaten in the green state, and well cooked, but apt to produce flatulence unless combined with spices. In the dried or ripe state they are more difficult of digestion, and are apt to distend the stomach. Beans are mostly cooked by boiling in water, to which a little salt of tartar has been added, to preserve their green color.

BEANS, CULTIVATION OF. Beans should succeed a grain crop, provided the ground is in decent order, and not worn out by previous working. Less than *four* bushels of seed ought not to be used per acre, and this is best sown by running the drill-barrow after every third plough; afterwards harrowing before the young plants reach the surface.

Dung is frequently given to beans, especially when they succeed wheat, that had not received manure. It is best applied on the stubble, before the winter ploughing is given, or it may be thrown into the drills with the seed. Beans require hoeing or earthing up, which is sometimes done by hand or plough; they also require weeding, which must

be done by hand, after the hoeing. Before beans are cut they should be well ripened, and may be generally harvested at the end of September or beginning of October. They should be cut with the sickle and tied in sheaves, and in stacking them a "*bole*," or air funnel, should be left in the centre of the stack, in such a manner that a current of air may pervade the whole. (See BARLEY.)

BEAR'S GREASE. This fat is much esteemed for promoting the growth of the hair, but in reality possesses no superiority over any other animal fat. The mass of that which is sold in England is hog's lard. The quantity annually consumed in Great Britain and exported, is estimated at several tons, being a larger quantity than all the bears at present procurable in Europe would supply, if slaughtered and roasted for their fat.

BEAR'S GREASE. (FACTITIOUS.) *Prep.* Hog's lard 16 oz.; flowers of benzoin and palm oil, of each ½ oz. *Proc.* Melt together until combined, and stir until cold. *Remarks.* This article does not readily become rancid by age, and may be scented at pleasure.

BECHAMEL, (IN COOKERY.) A variety of fine white broth, or consommée, thickened with cream. *Proc.* Cut lean veal and ham or bacon into small slices, put them into a stewpan with a good piece of butter, an onion, a blade of mace, a few mushroom-buttons, a bit of thyme, and a bay-leaf; fry the whole over a very slow fire, but not to brown it; thicken it with flour. Add an equal quantity of good veal or mutton broth, and cream. Let it boil gently one hour, stirring it all the time. Strain it through a soup-strainer.

BEECHWOOD MAHOGANY. *Prep.* Dissolve 2 oz. of dragon's blood and 1 oz. of aloes in 1 quart of rectified spirit of wine, and apply it to the surface of the wood previously well polished.

II. Wash over the surface of the wood with aquafortis, and when thoroughly dry give it a coat of the above varnish.

III. Boil 1 lb. of logwood chips in 2 quarts of water, and add 2 handfuls of walnut peels; boil again, then strain, and add 1 pint of good vinegar, as above.

BEEF. *Qual.* The flesh of a bullock, not past the middle age, is very nutritious, and especially adapted to persons of good appetite, or that labor, or take much exercise. It is also well suited for persons of delicate constitutions, if not overcooked, and left full of gravy, in which case it will sit lightly on the stomach, and its fat prove almost as digestible as that of veal.

Choice. Ox beef is considered the best, and may be known by having a fine smooth open grain, a good red color, and a tender texture. The fat should look whitish yellow, or but slightly yellow. Cow beef has a closer grain than ox beef, and the lean a deeper red; bull beef is closer still, the fat hard and skinny, the lean of a deep red, and it has a stronger smell. Heifer beef resembles ox beef, except in being smaller, for which reason it is preferred in some families. The best roasting pieces are the sirloin and the long ribs, but the short ribs and the silver side of the round are also sometimes roasted, but do not turn out so well. These pieces are much improved by being steeped for three or four hours in a marinade made with three parts of water and one of vinegar, before roasting.

BEEF A-LA-MODE. *Prep.* I. "Cut out the bone from the beef, and convert it, with the trimmings, into gravy; then stuff the orifice with rich forcemeat. Half roast it, and before it is put into the stewpan, lard the top with dried and pickled mushrooms, adding mushroom-powder in the orifices; then put in two quarts of gravy from the bones, a large onion stuck with cloves, and two carrots cut in slices. When the beef has stewed till it is quite tender, strain and thicken the sauce, add to it a glass of wine, mushrooms, and oysters, and sippets of fried paste: either the mushrooms or oysters may be omitted, if the flavor of either should not be desirable."

II. "Take 3 lbs. of the rump, or any part of the beef which will stew well; trim it nicely, and cut off all the fat. Chop all sorts of sweet herbs together very finely, with a little shalot, and a great deal of spice, and put them into a saucer of vinegar, that has been rubbed with garlic. Cut fat bacon into long slips and dip it into the herbs and vinegar; lard the beef regularly on both sides, if necessary, in order that it should be thoroughly flavored; rub the beef over with the herbs and spice; flour the meat, add a piece of butter, the size of a walnut, rolled in flour, and a pint of water. Bake the beef in an oven, strain the gravy, which will scarcely require either thickening or browning, and serve it up with pickles on the top. It is most excellent when cold, but should be served up hot at first. The gravy may be boiled to a glaze if necessary. It will require a good deal of spice; a teaspoonful of cayenne pepper, one of white pepper, a saltspoonful of allspice, half the quantity of pounded cloves, and a blade of mace pounded, or the mixed spices may be used."

BEEF, COLLARED. "Take the best part of a shin of beef, of which soup has been made, (for it must be stewed until very tender,) and an ox-tail, also well-stewed; cut them into small pieces, season them well, add a glass of wine and a glass of ketchup, and put it into a stewpan covered with a part of the liquor in which the ox-tail has been boiled; stew it for about twenty minutes, and then put it into a mould. It must be very cold before it is turned out. This is a good way of employing the beef and heel when soup or jelly is made; a few chopped sweet herbs may be added, and hard eggs cut into slices, or pickles, such as sliced cucumbers, intermingled. The flavor may be varied in many ways."

BEEF, DUTCH. *Prep.* Cover lean beef with a mixture of treacle and moist sugar, for three days, then salt it well with common salt and saltpetre, rubbed well in, and turn it well every day for a fortnight. It must then be rolled tight in a coarse cloth, and submitted to heavy pressure, after which it is to be hung up in wood smoke, and turned every day. If after boiling it be well pressed it will grate or cut in "shivers" equal to the finest Dutch beef. One pound of salt is enough for twelve pounds of beef.

BEEF, HAMBURGH. *Prep.* This is prepared by pickling the beef for three weeks, with a mixture of 1½ lb. of salt, 1 lb. of treacle, and 1½ oz. of saltpetre, well rubbed in, after which it is dried in wood smoke. The ribs is the part generally

used, of which the above pickle will be enough for 15 to 18 lbs.

BEEF, HUNG. *Prep.* I. Choose a piece of beef with as little bone as you can, (the flank is best,) sprinkle it, and let it drain a day; then rub it with salt and saltpetre, but only a small proportion of the latter; and you may add a few grains of cochineal; all in fine powder. Rub the pickle every day into the meat for a week, then only turn it.

It will be excellent in eight days. In sixteen drain it from the pickle; and let it be smoked at the oven's mouth when heated with wood, or send it to the baker's. A few days will smoke it.

A little of the coarsest sugar may be added to the salt.

It eats well boiled tender with greens or carrots. If to be grated as Dutch, then cut a *lean* bit, boil it till extremely tender, and while hot put it under a press. When cold, fold it in a sheet of paper, and it will keep in a dry place two or three months, ready for serving on bread and butter.

II. Rub the beef with one eighth of its weight of salt, to which a little saltpetre has been added, then put it into a tub or other suitable vessel, place a board over it, and pile heavy weights upon it; let it remain so for fourteen to twenty days, then take it out and hang it up for three weeks or a month to dry.

BEEF, HUNTER'S. *Prep.* To a round of beef, weighing twenty-four pounds, take three ounces of saltpetre, three ounces of the coarsest sugar, an ounce of cloves and nutmeg, half an ounce of allspice, and three handfuls of common salt, all in the finest powder. Allow the beef to hang two or three days, remove the bones, then rub the spices well into it, continuing to do so every day for two or three weeks. Before dressing it, dip it into cold water to take off the loose spice. Bind it up tightly with tape, and put it into a pan with a teacupful of water at the bottom; cover the top of the meat with shred suet, and cover the pan with a coarse crust, and brown paper over it. Let it bake five hours, and when cold take off the paste and the tape.

BEEF, LEICESTER SPICED. *Prep.* Take a round of beef, rub in a quarter of a pound of saltpetre, finely pounded; let it stand a day, then season it with half a pound of bay-salt, an ounce of black pepper, and the same of allspice, *both pounded.* Let it lie in the pickle a month, turning it every day.

BEEF, PICKLED. *Prep.* Rub each piece of beef very lightly with salt; let them lie singly on a tray or board for 24 hours, then wipe them very dry. Pack them closely in a tub, taking care that it is perfectly sweet and clean. Have the pickle ready, made thus: Boil four gallons of soft water with ten pounds of coarse salt, four ounces of saltpetre, and two pounds of coarse brown sugar; let it boil 15 minutes, and skim it while boiling very clean. When perfectly cold pour it on the beef, laying a weight on the top to keep the meat under the pickle. This quantity is sufficient for 160 lbs. of beef if closely packed.

BEEF, POTTED. *Prep.* Cut the beef small, add to it some melted butter, 2 anchovies, boned and washed, and a little of the best pepper, all pounded very fine. Beat the whole well together in a marble mortar, until the paste is very smooth and yellow colored, then put it into pots and pour clarified butter over it, about $\frac{1}{4}$ of an inch deep.

BEEF, WELSH. *Prep.* Rub two ounces of saltpetre into a round of beef, let it remain an hour, then season it with pepper, salt, and a fourth portion of allspice; allow the beef to stand in the brine for 15 days, turning it frequently. Work it well with pickle; put it into an earthen vessel, with a quantity of beef-suet over and under it, cover it with a coarse paste and bake it, allowing it to remain in the oven for 6 or 8 hours. Pour off the gravy, and let the beef stand till cold. It will keep for two months in winter, and will be found useful amid the Christmas fare in the country.

BEER, ALE, AND PORTER. *Qual., &c.* Pure malt liquor, which has undergone a perfect fermentation, is perhaps the most wholesome beverage that can be drunk provided it be not taken in excess. Malt liquor bears different names according to its strength and color. Ale is the most nutritious variety, but *good* porter frequently agrees better with bilious constitutions. The most wholesome and perhaps the least exceptionable beverages prepared from malt are those known as East India, Scotch, and Bavarian ales. A late writer has described good beer as *nutritious,* from the sugar and mucilage it contains; *exhilarating,* from its spirit; and *strengthening* and *narcotic,* from its hops. The stronger varieties of ale contain 7 to 8 per cent. of absolute alcohol; average strong ale 5 to 6 per cent.; brown stout 6 to 7 per cent.; London porter $3\frac{1}{2}$ to 4 per cent.; and table beer 1 to 2 per cent. (See BREWING, ALE AND MALT LIQUOR.)

BEER, AMBER. *Prep.* Amber is now out of fashion, but formerly was drunk in great quantities, in London, mixed with bitters, and called purl. The proportions of malt were three quarters amber, and one quarter pale, with six pounds of hops to the quarter. The first liquor is usually turned on at 170°, and the second at 185°. The worts are boiled together for two hours. It is tunned at 64°, and after 24 hours roused every 2 hours, till the heat is increased to 74°. It is then skimmed every hour for 6 hours and cleansed, and generally used as soon as it has done working in the barrels.

BEER, BRAN. A very good article of table beer may be brewed from bran, especially if it be mashed with about $\frac{1}{16}$ of its weight of good malt. A proportionate quantity of hops must be used, and the addition of a little moist sugar will vastly improve it. Bran will yield from 16 to 20 lbs. per barrel, with proper management.

BEER, CHEAP. "No production of this country abounds so much with saccharine matter as the shells of green peas. A strong decoction of them so much resembles, in odor and taste, an infusion of malt (termed wort) as to deceive a brewer. This decoction, rendered slightly bitter with the wood sage, and afterwards fermented with yeast, affords a very excellent beverage. The method employed is as follows:

"Fill a boiler with the green shells of peas, pour on water till it rises half an inch above the shells, and simmer for three hours. Strain off the liquor,

and add a strong decoction of the wood sage, or the hop, so as to render it pleasantly bitter; then ferment in the usual manner. The wood sage is the best substitute for hops, and being free from any anodyne property is entitled to a preference. By boiling a fresh quantity of shells in the decoction before it becomes cold, it may be so thoroughly impregnated with saccharine matter as to afford a liquor, when fermented, as strong as ale."

BEER, POTATO. An excellent beverage may be prepared by mixing the pulped potatoes with about $\frac{1}{12}$ of their weight of good barley malt, and mashing with water at 160°, keeping it at the same temperature for 4 hours; after draining off this wort, a second mash must be made at 180° for 1 hour; the mixed worts must be then boiled with a little hops, cooled and fermented.

BEER, SPRUCE. I. (*White.*) *Ing.* Water 10 gallons; sugar 10 lbs.; essence of spruce ¼ lb.; yeast ½ pint. *Proc.* Dissolve the sugar and essence of spruce in the water, previously warmed; then allow it to cool a little, and add the yeast, as in making ginger-beer; bottle immediately in half-pint bottles.

II. (*Brown.*) For sugar use treacle. *Remarks.* Spruce beer is a pleasant beverage, when well prepared, and possesses slightly diuretic properties.

BEER, SUGAR. *Prep.* Mash a peck of bran in 10 gallons of boiling water for 2 hours, draw off the wort, add 7 lbs. of moist sugar, and boil it with a ½ lb. of hops; then cool it down and add a little yeast. It may be put into the cask the next day, and in 3 days more it may be bunged down. At the expiration of 6 or 8 days it will be fit to drink. This beer will not keep long.

BEER, SUGAR AND MALT. *Prep. &c.* It has been found that 100 lbs. of good moist sugar, mixed with 1 quarter of malt, will produce an equal quantity of wort, and of the same quality, as 2 quarters of malt would do under similar treatment. The best plan is to add the sugar to the wort from the malt, after it is let down from the mash-tun. In other respects the brewing is the same as from malt alone.

BEER, TREACLE. *Prep.* Boil ½ lb. of hops with 14 lbs. of treacle in 36 gallons of water for 1 hour; then strain off the wort and add, when nearly cold, ½ a pint of yeast; the next day it may be put into a cask or bottled.

II. Hops 1 oz.; treacle 1 lb.; water 1 gallon. As above. *Remarks.* A cheap and pleasant beverage when well made. It will not keep for any length of time.

BEER, TABLE. *Prep.* I. Malt 1 bushel; hops ¾ lb. Draw off 1½ barrel of wort at three mashings. (See Brewing.)

II. Malt 8 bushels; hops 7 lbs.; sugar coloring 7 lbs.; Spanish juice 1 lb.; treacle 14 lbs. To produce 10 barrels, or five times the malt.

BEER, TWOPENNY (or *simply*, Twopenny.) *Prep.* Malt 3 bushels; hops 2 lbs.; Spanish juice 2 lbs.; treacle 14 lbs; capsicum ½ oz. To produce 1 barrel, or three times the malt. Drank in cold weather as a stimulant, frequently when only a week old.

BEES. In addition to what has been said under the article Apiary, the following will no doubt prove interesting to the reader.

Mr Cobbett on the management of Bees. The best hives are those made of clean unblighted rye-straw. A swarm should always be put into a new hive, and the sticks should be new that are put into the hive for the bees to work on; for, if the hive be old, it is not so wholesome; and a thousand to one but it contains the embryons of moths and other insects injurious to bees. Over the hive itself there should be a cap of thatch, made also of clean rye-straw; and it should not only be new when first put on the hive, but a new one should be made to supply the place of the former one every three or four months; for, when the straw begins to get rotten, as it soon does, insects breed in it, it smells bad, and its effect on the bees is dangerous.

The hives should be placed on a bench, the legs of which mice and rats cannot creep up. Tin round the legs is best. But even this will not keep down ants, which are mortal enemies of bees. To keep these away, if they infest the hive, take a green stick and twist it round in the shape of a ring, to lay on the ground, round the legs of the bench, and at a few inches from it; and cover this stick with tar. This will keep away the ants.

Besides the hive and its cap, there should be a sort of shed, with top, back, and ends, to give additional protection in winter; though, in summer, hives may be kept too hot, and in that case, the bees become sickly, and the produce light. The situation of the hive is to face the south-east; or, at any rate, to be sheltered from the north and the west. From the north always, and from the west in winter. If it be a very dry season in summer, it contributes greatly to the success of the bees, to place clear water near their home, in a thing that they can conveniently drink out of; for, if they have to go a great way for drink, they have not much time for work.

It is supposed that bees live only a year; at any rate, it is best never to keep the same stall, or family, over two years, except it be wanted to increase the number of hives. The swarm of this summer should always be taken in the autumn of the next year. It is whimsical to save the bees when the honey is taken. They must be fed; and if saved, they will die of old age before the next fall; and though young ones will supply the place of the dead, this is nothing like a good swarm put up during the summer.

A good stall of bees, that is to say, the produce of one, is always worth about two bushels of good wheat. The cost is nothing to the laborer. He must be a stupid countryman indeed who cannot make a bee-hive; and a lazy one indeed, if he will not if he can. In short, there is nothing but care demanded; and there are very few situations in the country, especially in the south of England, where a laboring man may not have half a dozen stalls of bees to take every year. The main things are to keep away insects, mice, and birds, and especially a little bird called the bee-bird; and to keep all clean and fresh as to the hives and coverings. Never put a swarm into an old hive. If wasps or hornets annoy you, watch them home in the day-time; and, in the night, kill them by fire or by boiling water. Fowls should not go where bees are, for they eat them.

On the different kinds of hives.—1. *The common hive.* This hive is too well known to require

any description. It should be made of good clean dry straw, and sufficiently thick and firm to protect the bees. The size of the hive should be proportionate to the size of the swarm placed in it. Care should be taken to avoid covering this hive with a hackle or turf, as it induces mice to build in it, and ultimately to destroy both combs and bees. 2. *Glass hives.* There are various modifications of this useful kind of hive. That of Mr. Moulton consists in placing glasses on a board furnished with holes at the upper part of a straw hive of peculiar construction; when filled with honey these may be removed without injury to the bees or disturbing the economy of the hive. The first year the glasses are only filled once, and generally produce about 8 lbs. of honey of superior quality; but the second year and subsequent years the glasses may be worked twice or oftener. 3. *The double cottage straw hive.* This hive is worked by first hiving the bees in the lower hive, and after 10 days clearing the opening at top and affixing thereon another small hive either of glass or straw. When full, the latter may be removed. 4. *The box hive and hexagon box and straw hives* may be worked in the common way, or by placing a glass hive over it. The management is very similar to the preceding varieties.

Bee-flowers. Bees seldom fly more than a mile for their food; it is therefore advisable to encourage the growth of such flowers as they appear to be most attached to. The following are said to be the most favorable for pasturage, and those that blossom early should be preferred:

Shrubs, &c.	*Flowers.*
Rosemary,	Mignonnette,
Broom,	Lemon thyme,
Heath,	Borage,
Furze,	White clover,
Fruit-blossoms.	Bean-flowers.

Swarming. As soon as a stock has increased to a certain number, which can barely find accommodation in the hive, an inclination to swarm is evinced as soon as a queen bee is ready to lead them. When the bees begin to carry in farina, or pellets on their thighs, it denotes that they have commenced breeding, which frequently begins in February, and does not finish till October. The indication of swarming is the clustering of the bees in great numbers below the resting-board. They never rise but in fine weather, and most frequently about noon; it becomes therefore necessary to observe the hives well during the swarming season, or from April to July. A second cast may generally be expected within 3 or 4 days after the first, but the interval seldom exceeds 8 or 10 days. Should a stock overswarm itself, it will perish unless strengthened; for this purpose, the number of bees that enter the hive should be carefully observed.

Hiving. The method of hiving a swarm of bees varies according to the object on which they may have settled. Should they alight on the ground, place a new hive over them, avoiding injuring any of the bees, or talking at the time, or breathing on them. Should they alight on a tree, the branch may be shaken over the hive, or if *small,* cut off and placed in it, and the hive left on the spot, when the remaining bees will go into it. The hive should then be left near to where they settle until the evening, when it may be gently removed to the bee-house. Ringing a bell, or beating an old kettle, is a common way of collecting the bees together and making them alight.

Reinforcement of weak stocks. Weak swarms of bees should be strengthened. This is done by hiving the swarms as usual, and in the evening striking the bottom of the hive containing the new swarm smartly, on a cloth spread upon the ground. The bees then fall in a cluster on the cloth, when the hive containing the stock to be reinforced must be placed over them as quickly as possible; after the lapse of about a quarter of an hour, they will have become united as one family. Another method is to invert the one hive and to place it in a bucket or pail, then to set the other hive over it; by the next morning the bees in the lower one will have ascended into the upper. The operation of reinforcing stocks is very economical, as it is found that one strong stock will produce more honey than two weak ones.

Weak stocks. Stocks weighing less than 18 or 20 lbs. cannot be safely brought through the winter without feeding. The best food is a mixture of sugar and water, or equal parts of sugar and beer.

BEETLES. The common pest of our kitchens, to which this name is applied, is properly the *blatta* or *cockroach*, which is an insect of the order orthopterous, and not belonging to the coleopterous, or beetle tribe. The blatta, or cockroach, is characterized by its nocturnal appearance, retiring during the day to the cracks and holes in the floors and walls surrounding the fireplaces. It is principally found on the basement floor, and likes a warm damp situation.

Exter. Place a few lumps of unslaked lime where they frequent; or set a dish or trap, containing a little beer or sirup at the bottom, and place a few sticks slanting against its sides, so as to form a sort of gangway for the beetles to climb up by, when they will go headlong into the bait set for them. Another plan: mix equal weights of red lead, sugar, and flour, and place it nightly near their haunts. This last mixture, made into sheets, forms the beetle-wafers, sold at the oil shops.

BEET ROOT. *Qual., Use, &c.* Beet root is cooling, saccharine, and nutritious, and is much used for its color in cookery. It is cooked by either boiling or baking, with a little vinegar and gravy, and is also used as an ingredient in several excellent winter salads. Under the name of mangel wurzel it is much employed for feeding cattle.

BEET ROOT SUGAR. *Prep.* This is made by expressing the juice of the white-rooted beet, and afterwards boiling the marc in water, and again expressing the liquor. The fluids are then mixed, evaporated to the consistence of a sirup, clarified with white of egg, and lastly, evaporated to a proper consistence. *Remarks.* Beet root yields too little saccharine juice (and that of a very inferior quality) to be employed as a source of sugar, as long as cane-sugar is procurable at its present rate. The marc, or cake, left after the process, forms an excellent food for feeding cattle, and especially for pigs and cows.

BELLADONNIN. A volatile alkali, somewhat resembling ammonia, discovered by Luebe

kind in the atropa belladonna. (Phar. Centr. Blatt. für 1839.)

BELL METAL. A species of bronze applied to the manufacture of bells, &c.

Prep. I. Melt together under powdered charcoal, 100 parts of pure copper, with 20 parts of tin, and unite the two metals by frequently stirring the mass. *Remark.* Product very fine.

II. Copper 3 parts; tin 1 part; as above. *Remark.* Some of the finest church bells in the world have this composition.

III. Copper 2 parts; tin 1 part; as above.

IV. Copper 72 parts; tin 26½ parts; iron 1½ parts. *Remarks.* The bells of small clocks or pendules are made of this alloy in Paris.

Remarks. It is absolutely necessary in this process to keep the metals from contact with the air, for which purpose, the powdered charcoal is employed. The union of the two metals in this alloy is so complete, that its gravity is considerably greater than that of the mean of its constituents, thus evincing chemical union to have taken place.

The proportions of the first form are those of the Indian gong, so much celebrated for the richness of its tone. In very small bells, and in those of repeating watches, a little zinc is generally added, which makes them give out their tones the sharper. A less proportion of tin is now generally used for church bells, than for house or clock bells, the tones being thought to be rendered thereby more suitable to their respective purposes. The substitution of zinc for the iron in the last formula, would (I am told) improve the tone.

To give this alloy its highest degree of sonorousness, it must be subjected to sudden refrigeration. M. D'Arcet recommends the pieces to be ignited after they are cast, and then to be suddenly plunged into cold water. They are next to undergo a well-regulated pressure by skilful hammering, until they have assumed their intended form; then to be heated, and allowed to cool slowly in the air. In a general way, however, bells are formed by simple casting. The addition of lead, and other metals, to this alloy, greatly lessens its sonorousness. For common purposes the third form is generally used.

BENZAMIDE. A compound discovered by Wohler and Liebig, supposed to be formed by the union of the two theoretical bases benzule and amide, hence the name. *Prep.* Saturate chloride of benzule with dry ammoniacal gas, reduce the resulting dry white mass to a fine powder, and well wash it with cold water. Dissolve the residuum in boiling water; the benzamide will crystallize out on the liquor cooling. *Remarks.* Benzamide is soluble in water, alcohol, and ether, and is decomposed by both acids and alkalis.

BENZHYDRAMIDE. A compound discovered by Laurent. It is formed by the action of strong liquid ammonia, on $\frac{1}{20}$ of its volume of oil of bitter almonds, at a temperature of about 112°, and purified by boiling in ether, for some time, when crystals will be deposited on cooling. These are again dissolved in boiling alcohol, and purified by filtering and crystallization.

BENZILE. (Discovered by Laurent, who called it benzule, with which it is isomeric.) *Prep.* Pass chlorine gas over melted benzoin, until muriatic acid ceases to be formed; cool and dissolve in hot alcohol, which, on cooling, will deposite crystals of pure benzile. *Prop.* Soluble in alcohol and ether; tasteless, inodorous, volatile, and inflammable.

BENZILIC ACID. (Discovered by Liebig.) *Prep.* Boil benzoine or benzile with a saturated alcoholic solution of potassa, adding more of the latter, as long as a blue color is produced, after the previous portion has been decolored by boiling. Then neutralize with muriatic acid, filter and add muriatic acid in excess; on cooling, crystals of benzilic acid will be deposited. *Prop.* Soluble in water; fusible; with potassa and silver it forms benzilates of those bases, which are crystallizable.

BENZIMIDE. The pearly needles and lamellæ, which separate under certain circumstances from the essential oil of bitter almonds. It was discovered by Laurent, and has been thought by some to be dry benzoate of ammonia.

BENZOIC ACID. *Syn.* Flowers of Benzoin or Benjamin. *Prep.* There are two general methods of procuring this acid from gum benzoin: one by sublimation, or the "*dry way*," as it is commonly called; and the other, by dissolving it out in the form of a salt, from which the acid is afterwards procured; this has been called the "*moist way.*"

I. *By sublimation.*

a. Put 1 pound of coarsely triturated benzoin into an iron pot with a flat bottom, whose diameter is from 8 to 9 inches; the benzoin forming therein a layer of from 1 to 2 inches in depth. The open end of the pot is then to be covered with a sheet of soft and loose blotting paper, (felt, Liebig,) which must be attached to the rim with paste. A cone, formed with strong and thick paper, (cartridge paper,) is then to be capped over the top of the pot, including the blotting paper; and this is also to be attached with paste and string. The apparatus thus prepared, should then be placed on the sand-bath, and exposed from 4 to 6 hours to a gentle heat. After this lapse of time, it may be removed from the sand-bath, inverted, and the string detached, when beautiful white needles, of a silky lustre, possessing the agreeable odor of benzoic acid, will be found in the paper cone.

Prod. From 1 lb. of good benzoin 1½ to 2 oz. of benzoic acid may be procured. The second sublimation ordered in the London Pharm. becomes quite unnecessary when the above method is followed. The following modification of the above is highly recommended by Gauger.

b. Place 12 oz. of coarsely powdered benzoin resin, mixed with sand, in a flat iron vessel capable of containing from 2 to 4 lbs.; cover the mouth of the vessel with loose blotting paper, place therein a stick to support 4 or 5 paper discs, at some distance above the blotting paper, horizontally fixed on the stick; then tilt a paper bag in the form of a sugar-loaf, and formed of a double sheet of paper, (inward blotting paper, and outward sugar paper,) over it, and attach this apparatus by means of a string, around the brim of the vessel. After 6 or 8 hours' exposure in a sand-bath, allow it to cool; take out the benzoic acid from the bag and the paper discs, renew the paper attached over the mouth of the vessel, and again arrange the whole as before, when it must be heated for some hours to a higher temperature. It is advisa-

ble to renew the paper for a third time. The white crystals are separated from the product, the colored crystals strongly pressed between folds of blotting paper, and again sublimed as before. 12 oz. of good benzoin thus furnish from 10 to 11 drachms of fine benzoic acid. Some benzoic acid may afterwards be obtained from the papers employed. (Gauger's Report, 1842.)

c. (*Process at Apothecary's Hall.*) The best gum benzoin is put into an iron pot, set in brickwork, over a proper fire, and communicating by a conical metal neck, with a wooden box lined with paper, as a receiver for the flowers. The sublimation is conducted rather rapidly, and the acid condenses in beautiful elastic prismatic crystals; but if the process be conducted more slowly, the product is proportionately scaly. *Prod.* 10 to 12 per cent. of flowers are thus generally procured, which, after being pressed in blotting paper, are again sublimed, and give 8 or 9 per cent. of very pure acid.

II. *By the moist way.*

a. (*Scheele's process.*) Mix intimately together, equal parts of finely powdered benzoin and hydrate of lime, and boil for 1 hour, with 40 parts of water; filter and evaporate to one-fifth; saturate the lime with muriatic acid, when the benzoic acid will crystallize out as the liquor cools; it should be then either washed or sublimed, after first well drying it. *Remarks.* If a *perfect* mixture of the lime and powdered gum be not first made, the latter will run into a solid mass in the boiling water, and the process will fail. 1 lb. of benjamin yields ℥j, ʒvj, ℈ij of flowers. (Gray.) By my own manipulations I could never succeed in procuring this proportion of acid. The above process is similar to that of the Dublin Pharmacopœia.

b. (*Process of Stoltze.*) Dissolve the resin in 3 times its weight of alcohol, introduce the solution into a retort, and add thereto gradually, a solution of carbonate of soda in weak spirit and water, until all the free acid be neutralized; water equal to twice the weight of the benzoin employed, must be next poured in, and the alcohol removed by distillation. The floating resin should be now skimmed off the remaining liquid, and washed with a little water, which should be added to the contents of the retort, which will deposite crystals on cooling.

c. Boil hippuric acid for 15 minutes in nitric acid, sp. gr. 1·42, then add water, and allow the solution to crystallize; collect the crystals, and purify by sublimation as above. *** Hippuric acid is manufactured from the urine of horses, which is evaporated to ⅛ of its original volume, and then mixed with muriatic acid; after which, the liquid deposites the acid, somewhat impure, under the form of a crystalline powder. Large quantities of benzoic acid are said to be obtained by the above process, but owing to its not being generally well purified, is of inferior quality and unsaleable. It may, however, be rendered quite equal to that obtained from gum benzoin, by careful manipulation. "*A manufactory of sal ammoniac, near Magdeburgh, which uses urine, is able to supply flowers of benjamin by the cwt.*" (Gray.)

Remarks. The manufacture of benzoic acid has lately assumed considerable interest from the scarcity and high price of gum benzoin, which is now from 40*l.* to 50*l.* the cwt. The low price at which this acid has for some time past been sold, is barely sufficient to repay the expenses incurred in its manufacture. The finest gum benzoin is exported in large quantities to Spain, where it is mixed with olibanum and used as incense. Benzoic acid is at the present time very dear, being about 1*s.* 7½*d.* to 1*s.* 8*d.* an ounce, whereas, its usual price averages from 1*s.* ½*d.* to 1*s.* 2*d.* the oz. A large manufacturer, with whom I am acquainted, made a sale some time since at 1*s.* 1½*d.*, of about 300 oz., but has lately greedily taken back the greater portion, which remained unsold, at 1*s.* 4*d.*, besides paying all the expenses of transit, &c.

The product by the process of sublimation is generally greater than by the humid way, and is consequently the one usually adopted. Much, however, depends upon the quality of the gum employed. It is found to be the most economical to use the best benzoin, as it is richer in benzoic acid than the inferior kinds.

Prop., Uses, &c. Form; light feathery white crystals; very soluble in alcohol. It is used in making paregoric, and is sometimes administered in chronic bronchial affections; it is expectorant. *Dose.* 10 to 20 grs. in old coughs.

Pur. 24 parts of boiling water dissolve 1 part of benzoic acid, and again deposite the greater portion on cooling. Freely soluble in alcohol, and in liquor of potassa, from which it is precipitated by adding muriatic acid. When cautiously heated, it wholly evaporates, with an odor of benzoin. It is inflammable. (P. L.)

BENZOATES. Combinations of the bases with benzoic acid.

Prep. The benzoates of ammonia, soda, and potassa, may be made by dissolving with heat benzoic acid in their respective aqueous solutions, until they become perfectly neutral. Most of the other benzoates may be formed in a similar way, or by adding a benzoate of an alkali to a salt of the base.

BENZOINAMIDE. *Syn.* HYDROBENZOINAMIDE. A white, tasteless, inodorous, volatile powder, obtained by heating benzoin with water of ammonia.

BENZOIN. *Syn.* CAMPHOR OF OIL OF ALMONDS. A compound isomeric with benzule, discovered by Robiquet and Boutron Charlard. *Prep.* Mix together equal parts by measure of the raw oil of bitter almonds, and a solution of caustic potassa in alcohol. As soon as the liquid becomes full of crystals, and apparently solid, it must be dissolved in alcohol, filtered, and crystallized. *Prop., &c.* Brilliant prismatic crystals; tasteless, odorless, volatile, and inflammable; soluble in alcohol, and forming with oil of vitriol, and with alcoholic solution of potash, a violet-blue solution.

BENZOLE. *Syn.* BENZINE. Discovered by Faraday among the products of the destructive distillation of organic substances; it resembles ether. *Prep.* Submit a mixture of 1 part of benzoic acid and 3 parts of slaked lime, to distillation, and redistil the oily product with water.

BENZONE. *Syn.* CARBOBENZIDE. An oily liquid, heavier than water, discovered by Mitscherlich and Peligot. *Prep.* The raw product of

the distillation of benzoate of lime, is distilled first in a water-bath, and then afterwards until the heat gradually rises to 920°, as long as benzole comes over. The product is next exposed to a cold of −5°, when the crystals of naphthaline which form must be separated from the liquid, which is pure benzone.

BENZULE. The hypothetical radical of several compounds obtained from the oil of bitter almonds, and supposed to be the base of benzoic acid. Among the principal members of this group may be mentioned *hydruret of benzule*, obtained from a mixture of oil of almonds, milk of lime, and chloride of iron, by distillation; the *chloride of benzule*, obtained from the last article (rendered dry by chloride of calcium) by passing chlorine gas through it, as long as muriatic acid is formed; the *bromide of benzule*, also prepared like the chloride; the *iodide of benzule*, prepared from a mixture of iodide of potassium and chloride of benzule by distillation; the *sulphuret of benzule*, prepared by distillation from a mixture of sulphuret of lead and chloride of benzule; and *cyanuret of benzule*, also prepared by distillation, from a mixture of bicyanide of mercury and chloride of benzule. The series also includes hippuric acid, amygdalinic acid, and amygdaline, as well as several other substances whose names contain (benz-) the first part of the word benzule, as indicative of their constitution.

BERBERINE. A substance discovered by Buchner, in the barberry shrub, (berberis vulgaris.) It belongs to the class of azotized coloring substances. It is soluble in boiling water and in alcohol, from either of which it may be obtained in crystals.

BETULINE. *Syn.* Betulina. A substance discovered by Löwitz, in the bark of the white birch, (the betula alba.) It is obtained under the form of white crystalline needles, soluble in ether, alcohol, oil, and acids. It is fusible, volatile, and inflammable.

BEZOARS. Preternatural concretions found in the stomach and intestines of some animals, formerly supposed to possess alexipharmic powers, and were both taken internally and worn as amulets. They have now, however, sunk into disuse, and though ordered in the preparation of Gascoigne's ball and powder, a factitious kind is substituted. The name bezoar was formerly extended to various other substances supposed to possess similar virtues.

BEZOARS, FACTITIOUS. *Prep.* Make tobacco-pipe clay into a paste with ox-gall, and add a little hair or wool; then form into shapes.

Remarks. This will give a yellow tint to paper, rubbed with chalk, and a green one to quicklime, which tests are considered as proof of genuine bezoars.

BEZOAR, MINERAL. Powder of algaroth deflagrated with nitre in a red hot crucible, and then well washed with water. Once used in doses of 5 to 15 grs. as a diaphoretic, but now obsolete. According to the mode by which the powder of algaroth was made, arose the names bezoardicum joviale and bezoardicum martiale, also applied to this preparation.

BEZOAR, ARGENTINE. *Syn.* Bezoardicum Lunare. Made by distilling a mixture of butter of antimony and nitrate of silver. Once given in epilepsy and head diseases, in doses of 6 to 12 grains.

BEZOAR OF LEAD. *Syn.* Bezoardicum Saturni. Made by distilling a mixture of oxide of lead, butter of antimony, and nitric acid. Once given in doses of 5 or 6 grs. in diseases of the spleen.

BHAURTA, (in Cookery.) An Indian dish made with mashed potatoes, onions, and capsicum, moulded into a shape and slightly baked.

BIBROMISATINE AND BROMISATINE. These are formed by the action of bromine on isatine. Treated with potassa, they yield acids of the same names.

BICARBONATES. Combinations of the bases with the carbonic acid, in which two atoms of the latter are united to one of the former. The following are the principal bicarbonates.

BICARBONATE OF POTASSA. *Syn.* Aerated Kali. *Prep.* There are two methods of preparing this salt: one, by passing a stream of carbonic acid through a solution of the carbonate of potassa; the other, by the addition of sesquicarbonate of ammonia. The processes of the London and Edinburgh colleges offer an example of each.

I. *a.* (*Process of the L. Ph.*) *Ing.* Carbonate of potassa ℔. vj; distilled water 1 gallon. *Proc.* Dissolve the salt in the water, and pass carbonic acid gas through the solution, to saturation; apply a gentle heat to redissolve any crystals that may have been deposited, then set the liquor aside to crystallize; lastly, pour off the liquid and dry the crystals.

_ The carbonic acid may be obtained from chalk or whiting, rubbed up with water to the consistence of a sirup, upon which oil of vitriol, diluted with an equal weight of water, is to be poured.

b. (*Process at Apothecaries' Hall.*) *Ing.* Carbonate of potassa 150 lbs.; distilled water 17 gallons. *Proc.* Dissolve 100 lbs. of the carbonate in the water; then saturate with carbonic acid gas as last, when 35 to 40 lbs. of crystals of bicarbonate of potassa may be obtained. The remaining 50 lbs. of the carbonate are now dissolved in the mother liquor, and enough water added to make it up a second time to 17 gallons, the remaining part of the operation being performed as before. This plan may be repeated again and again.

Remarks. The following plan has been proposed as a substitute for the preceding process, but does not produce a pure salt. Dissolve pearlash in water; add bran or sawdust, to soak up the liquor; put it into a crucible, lute on the cover, and heat it to redness; cool, wash out the salt, evaporate, and crystallize. Repeat the process with the remaining liquor. Yields a very imperfect salt.

II. (*Process of the Ed. Pharm. Cartheuser's Process.*)

a. Carbonate of potassa 6 oz.; sesquicarbonate of ammonia 3½ oz. *Proc.* Triturate together, and when reduced to a very fine powder and perfectly mixed, make them into a stiff paste with water. Dry this very carefully at a heat not higher than 140° Fahr. until a fine powder, perfectly devoid of ammoniacal odor, be obtained, occasionally triturating the mass towards the end of the process.

b. (*Process of Henry and Guibourt.*) Dissolve 500 parts of pure carbonate of potassa in 1000 parts of water; filter, if necessary, and place the fluid in a porcelain capsule; set in a salt-water bath,

and add gradually 300 parts of sesquicarbonate of ammonia. Slightly agitate the liquor until ammoniacal fumes are perceived; then filter over a heated vessel, and set it aside to cool. *Remarks.* The process recommended by Geiger is similar to the last, but the proportions are 1 lb. of carbonate of potassa and 1 lb. 6 oz. of sesquicarbonate of ammonia.

Prop. Use, &c. It is soluble in 4 times its weight of water at 60°; is fixed in the air, but decomposed into a carbonate at a red heat. It possesses the general alkaline properties of carbonate of potassa, but in an inferior degree. It is much used as an antacid, and for making effervescing saline draughts. The *dose* is from 10 grains to ½ a drachm.

20 grs. bicarbonate of potassa in crystals

saturate

14 grs. of crystallized citric acid;
15 grs. " tartaric acid; and
½ oz. of lemon juice.

Pur. and Tests. A solution of corrosive sublimate merely causes an opalescence, or very slight white precipitate in a solution of this salt; if it contains carbonate of potassa a brick-colored precipitate will be thrown down. In other respects it may be tested like the carbonate, which see.

BICARBONATE OF SODA. *Syn.* AERATED SODA. This is prepared in a similar way to the bicarbonate of potassa.

I. *a.* (*Sesquicarbonate of Soda*, P. L.) *Ing.* Carbonate of soda, lb. vij.; water 1 gallon. *Proc.* Dissolve and pass carbonic acid through the solution, in the same way as in making the bicarbonate of potassa.

b. Dissolve 160 lbs. of carbonate of soda in 13 gallons of water, and pass carbonic acid through the solution. The bicarbonate falls down to the amount of about 50 lbs., and may be collected and dried by pressure in an hydraulic press. A fresh portion of soda may be then dissolved in the mother liquor, and the whole process repeated as before. (Brande.)

c. Mix together 1 part of carbonate of soda, with 2 parts of dried carbonate of soda, both in powder, and surround them with an atmosphere of carbonic acid gas, under pressure. Let the action go on till no more gas is absorbed, which will generally occupy 10 to 14 hours, according to the pressure employed, then remove the salt and dry it at a heat not above 120°. This process is a modification both of that of the Edinburgh Pharmacopœia and that of Mr. Smith, described in the Philadelphia Pharmaceutical Journal. Smith, however, employs the salt in crystals. In Scotland the method just described has been adopted with perfect success, and I can, from my own experience, bear testimony to its efficiency.

Remarks. A crude sesquicarbonate of soda has been prepared as follows: Calcine carbonate of soda with bran, as in making bicarbonate of potassa; wash out the salt and crystallize: very inferior.

II. *Ing.* Carbonate of potassa and water, of each 1 lb.; carbonate of ammonia ¾ lb. *Proc.* Dissolve the carbonate in the water, then add the ammonia, and drive off the ammoniacal fumes at a heat under 120°; lastly, set the solution aside to crystallize. *Remarks.* The above are nearly the proportions of the P. L. of 1809. Winckler, however, directs 80 of carbonate of soda, 3 of carbonate of ammonia, and 20 of water; and Henry and Guibourt order 6 parts of the soda, 2 of the ammonia, and 4 of water. The processes I. *b* and I. *c* are those adapted for commercial purposes.

Prop., Use, &c. These are very similar to the carbonate of soda, but it is more feebly alkaline. It loses a part of its acid by heat. The *dose* is from 10 to 40 grains, as an antacid and absorbent. It is largely employed in the preparation of effervescing powders and draughts, for which purpose

20 grs. of commercial bicarbonate of soda

are taken with either

18 grs. of crystallized tartaric acid;
17 grs. of crystallized citric acid; or
½ oz. of lemon juice.

Tests and Pur. Dissolved in 40 parts of water it does not give a reddish precipitate with a solution of corrosive sublimate. (P. E.) It is totally dissolved in water; neither chloride of platina nor sulphate of magnesia throws down any thing from this solution. It is converted into the anhydrous carbonate by heat. (P. L.) The quantity of bicarbonate any given sample contains may be pretty nearly ascertained by well washing 100 grains of the salt with an equal weight of water, and filtering the solution. The residuum left upon the filter, dried at a heat of 120° and weighed, will give the per centage of bicarbonate of soda present, (very nearly.) Dissolved in water this will give only a trifling white precipitate, with corrosive sublimate, as described above, while the filtered portion, which was used to wash the salt, will give a red one, if it contains the simple carbonate of soda.

BICE, BLUE. The native blue carbonate of copper, prepared by grinding and washing. *Use.* As a pigment.

BICE, GREEN. The native green carbonate of copper, prepared as above. *Use.* As a pigment.

BILE, BILIOUSNESS. *Treat., &c.* Persons subject to bilious attacks should be particularly careful to avoid excess in eating and drinking, and should especially avoid using those articles of food which, from experience, they find to disagree with them. A mutton chop under-cooked is an excellent article for the breakfast or lunch of a bilious patient; and mutton or beef, either broiled or roasted, so that the gravy be retained, is better for dinner than many articles apparently more delicate. These, with game and venison, form a good variety from which to choose a bill of fare. New beer and porter should be particularly avoided, as well as puddings and most articles of pastry, as they are very indigestible. Hard cheese, butter, unripe fruit, and especially beans, peas, and nuts, are also objectionable. An attack of bile may frequently be prevented by the use of a saline purgative, and it may generally be removed by an emetic, followed by a dose of castor oil, epsom salts, or seidlitz powders.

BILLS OF FARE. (In cookery and domestic economy.) Lists of the various articles of diet, either actually provided for use, or, being in sea

son, are procurable for that purpose. The following bills of fare, for which I am indebted to "The New System of Cookery," published by Mr. Murray, exhibits at a glance the various articles in season at different periods of the year, and which are usually found at those times upon the greater number of well-provided tables.

Bills of Fare for Family Dinners, &c., containing a list of various articles in season in different months of the year:

First Quarter. January.—Poultry: Game, pheasants, partridges, hares, rabbits, woodcocks, snipes, turkeys, capons, pullets, fowls, chickens, tame pigeons. *Fish:* Carp, tench, perch, lampreys, eels, cray-fish, cod, soles, flounders, plaice, turbot, thornback, skate, sturgeon, smelts, whitings, lobsters, crabs, prawns, oysters. *Vegetables:* Cabbage, savoys, colewort, sprouts, leeks, onions, beet, sorrel, chervil, endive, spinach, celery, garlic, scorzonera, potatoes, parsnips, turnips, brocoli, (white and purple,) shalots, lettuces, cresses, mustard, rape, salsafy, herbs of all sorts, dry and some green; cucumbers, asparagus, and mushrooms to be had, though not in season. *Fruit:* Apples, pears, nuts, walnuts, medlars, grapes.

February and March. Meat, fowls, and game, as in January, with the addition of ducklings and chickens; which last are to be bought in London most if not all the year, but very dear. *Fish:* As the last two months, except that cod is not thought so good from February to July, but may be bought. *Vegetables:* The same as the former months, with the addition of kidney-beans. *Fruits:* Apples, pears, forced strawberries.

Second Quarter. April, May, and June.—Meat: Beef, mutton, veal, lamb, venison, (in June.) *Poultry:* Pullets, fowls, chickens, ducklings, pigeons, rabbits, leverets. *Fish:* Carp, tench, soles, smelts, eels, trout, turbot, lobsters, chub, salmon, herrings, cray-fish, mackerel, crabs, prawns, shrimps. *Vegetables:* As before; and in May early potatoes, peas, radishes, kidney-beans, carrots, turnips, early cabbages, cauliflowers, asparagus, artichokes, all sorts of salads forced. *Fruit:* In June; strawberries, cherries, melons, green apricots, currants and gooseberries for tarts; pears, grapes, nectarines, peaches, and some other fruit; but most of these are forced, and consequently very dear.

Third Quarter. July, August, and September.—Meat as before. *Poultry:* Pullets, fowls, chickens, rabbits, pigeons, green geese, leverets, turkey poults. Two former months plovers, wheat-eaters; geese in September. *Fish:* Cod, haddock, flounders, plaice, skate, thornback, mullets, pike, carp, eels, shellfish, except oysters, mackerel the first two months of the quarter, but not good in August. Partridge shooting begins the 1st of September; what is used before is therefore poached. *Vegetables:* Of all sorts, beans, peas, French beans, &c., &c. *Fruit:* In July; strawberries, gooseberries, pine-apples, plums, various; cherries, apricots, raspberries, melons, currants, damsons. In August and September; peaches, plums, figs, filberts, mulberries, cherries, apples, pears, nectarines, grapes. Latter months, pines, melons, strawberries, medlars, and quinces; in the latter month, Morella cherries, damsons, and various plums.

Fourth Quarter. October, November, and December.—Meat as before, and doe venison. *Poultry and Game:* Domestic fowls as in former quarters; pheasants from the 1st of October; partridges, larks, hares, dotterels; the end of the month wild-ducks, teal, snipes, widgeon, grouse. *Fish:* Dories, smelts, pike, perch, halibuts, brills, carp, salmon-trout, barbel, gudgeons, tench, shellfish. *Vegetables:* As in January, French beans, last crop of beans, &c. *Fruit:* Peaches, pears, figs, bullace, grapes, apples, medlars, damsons, filberts, walnuts, nuts, quinces, services, medlars. In November—*Meat:* Beef, mutton, veal, pork, house lamb, doe venison, poultry and game as the last month. *Fish:* As the last month. *Vegetables:* Carrots, turnips, parsnips, potatoes, skirrets, scorzonera, onions, leeks, shalots, cabbage, savoys, colewort, spinach, chard-beets, chardoons, cresses, endive, celery, lettuces, salad-herbs, pot-herbs. *Fruit:* Pears, apples, nuts, walnuts, bullace, chesnuts, medlars, grapes. In December—*Meat:* beef, mutton, veal, house lamb, pork, and venison. *Poultry and Game:* Geese, turkeys, pullets, pigeons, capons, fowls, chickens, rabbits, hares, snipes, woodcocks, larks, pheasants, partridges, sea-fowls, guinea-fowls, wild-ducks, teal, widgeon, dotterels, dun-birds, grouse. *Fish:* Cod, turbot, halibuts, soles, gurnets, sturgeon, carp, gudgeons, codlings, eels, dories, shellfish. *Vegetables:* As in the last month. Asparagus forced, &c. *Fruit:* As the last, except bullace.

BIRCH SUGAR. *Prep.* This is prepared from the juice procured by boring a hole in the trunk of the birch tree, under one of the largest branches, carrying it quite through the wood to the bark on the opposite side. The juice that flows from the wood is collected in suitable vessels, and after mixing with a little chalk and clarifying with white of egg, is boiled down to a proper consistence.

BIRDLIME. *Prep.* Boil the middle bark of the holly, gathered in June or July, for 6 or 8 hours in water, until it becomes tender; then drain off the water, and place it in a pit under ground, in layers with fern, and surround it with stones. Leave it to ferment for two or three weeks, until it forms a sort of mucilage, which must be pounded in a mortar, into a mass, and well rubbed between the hands, in running water, until all the refuse is worked out; then place it in an earthen vessel, and leave it for four or five days to ferment and purify itself.

Remarks. Birdlime may also be made from mistletoe berries, the bark of the wayfaring tree, and other vegetables, by a similar process. Should any of it stick to the hands it may be removed by means of a little oil of lemon bottoms, or turpentine. *Use.* To rub over twigs to catch birds or small animals. It is said to be discutient when applied externally.

BIRDS *may be preserved* in a fresh state for some time by removing the intestines, wiping the inside out quite dry with a towel, and then flouring them. A piece of blotting paper, on which one or two drops of creosote have been placed, is now to be put inside them, and a similarly prepared piece of paper tied round them. They should then be hung up in a cool dry place, and will be found to keep much longer than without undergoing this process.

BISCUITS. A species of hard, dry, unleavened bread, made in thin flat pieces, and generally composed of flour and water, to which butter, sugar, almonds, and other articles are occasionally added.

BISCUITS, FANCY. *Prep.* Pound 1 lb. of blanched almonds very fine and sprinkle them with a little orange flower water; when reduced to a perfectly smooth paste put it into a small pan, and add a little of the finest flour; mix well and put the pan over a slow fire, and move the paste well about to prevent it burning, until it becomes hard enough not to stick to the fingers; then take it out and roll it into small fillets, and make it into knots, rings, or other shapes, as you may fancy. Next make an icing of different colors, and dip one side of your forms in it and set them to drain on a clean sieve. They may be varied by strewing over them pistachio nuts of different colors, according to fancy.

BISCUITS, SPONGE. *Prep.* Add the whites and yelks of twelve eggs, previously well beaten, to 1½ lbs. of finely powdered sugar, and whisk it until it rises in bubbles, then add 1 lb. of flour and the rind of two lemons grated. Form them into shapes, sift a little sugar over them, and bake them in buttered tin moulds, in a quick oven for one hour.

BISCUITS, DEVILLED. Butter captain's biscuits (or any similar kind) on both sides, and pepper them well, then make a slice of good cheese into a paste, with made mustard, and lay it on one side of each biscuit, spice with cayenne pepper, and grill them. Chopped anchovies, or essence of anchovies, is also a good addition.

BISMUTH. *Syn.* TIN GLASS. MARCASITE. Commercial bismuth is principally prepared in Germany, whence it is exported to England. In this state it generally contains both arsenic and copper. Chemically pure bismuth is made as follows:

Prep. Heat to redness, in a covered crucible, a mixture of the oxide, or subnitrate of bismuth, with half its weight of charcoal.

Use, &c. Bismuth is used in the composition of type metal, solder, pewter, fusible metal, and several other metallic mixtures. When added to other metals it renders them more fusible. An alloy of tin, nickel, bismuth, and silver is said to hinder iron from rusting. (Erdeman's Jour.)

Tests. Bismuth dissolves entirely in nitric acid, from which water and alkalis throw down a white precipitate, and sulphureted hydrogen a black one. The nitric solution is unaltered by adding sulphuric acid.

BISMUTH, BROMIDE OF. This is prepared by heating the metal with an excess of bromine in a glass tube, when a gray-colored mass, resembling fused iodine, is formed. It is volatile, and decomposed by water.

BISMUTH, CHLORIDE OF. *Prep.* Mix together two parts of corrosive sublimate and one part of bismuth, both in powder, and expose the mixture to heat until all the mercury be expelled; a granular substance of a grayish white color remains.

BISMUTH, ESTIMATION OF. I. (*When mixed with bodies unaffected by sulphureted hydrogen.*) Pass sulphureted hydrogen gas through the liquid previously mixed with a large quantity of acetic acid, and diluted with water. Collect the precipitated sulphuret on a filter, wash well with water, and redissolve in nitric acid in excess; dilute with water and filter; wash the sulphur left on the filter with water, soured with nitric acid; mix the whole together, and precipitate the bismuth in the state of oxide by carbonate of ammonia. Allow the liquor to stand for some hours, then collect the deposite on a filter, wash it with water, and ignite it in a porcelain crucible; lastly, weigh it. The weight, in grains of oxide multiplied by ·899, will give the weight of metal in the sample.

Remarks. Should the sample be in the solid state, it may be dissolved in nitric acid in excess, and precipitated by sulphureted hydrogen as above.

II. (*When neither mixed with muriatic acid nor substances precipitated by carbonate of ammonia.*) In this case the oxide of bismuth may be at once thrown down with carbonate of ammonia, ignited, and weighed as before.

III. (*When mixed with lead.*) *a.* "Ullgren precipitates the oxides with carbonate of ammonia and dissolves them in acetic acid; a strip of clean lead, the weight of which is known, is then put into this solution, so that the whole of it is covered. The vessel is closed and allowed to stand for some hours. Bismuth is separated in a metallic state, that which remains on the lead is washed off, and the strip dried and weighed. The bismuth is brought on to a filter and washed with water which has been boiled and allowed to cool; it is then dissolved in nitric acid, evaporated, heated, and the oxide of bismuth weighed. The solution of lead is precipitated with carbonate of ammonia, and the oxide determined. The loss of weight which the lead has suffered gives the quantity of oxide of lead which was not originally in the solution." (Berzelius Jahresbericht, 21.)

b. Add caustic potassa to the nitric solution, in sufficient excess to redissolve all the oxide of lead at first thrown down. The oxide of bismuth remains behind, and may be dried and weighed as before.

BISMUTH, FLOWERS OF. *Prep.* Mix together 2 lbs. of nitre and 1 lb. of bismuth, both in powder, and gradually inject them into an ignited tubulated earthenware retort, having a wide mouth and furnished with a receiver to catch the flowers.

BISMUTH, OXIDES OF. I. (*Protoxide.*) *Prep. a.* Expose the nitrate or subnitrate to a full red heat in a crucible. Color; yellow.

b. Dissolve 2 lbs. of bismuth in 2½ lbs. of nitric acid, and drop it gradually into a solution of 3 lbs. of carbonate of potassa in twice its weight of water; wash the precipitate well with cold water.

Remarks. This is much used by the ladies as a cosmetic. In medicine it has been used as an antispasmodic. *Color:* pearl white.

II. (*Peroxide. Syn. Deutoxide.*) *Prep.* Gently heat the protoxide for some time in a solution of chlorate of potassa, wash it well with water, and then dissolve out any undecomposed protoxide by digestion in dilute nitric acid, formed with 1 part of strong acid to 9 parts of water; afterwards again well wash it with water. A heavy brown powder.

BISMUTH, SUBCHLORIDE OF. *Syn.* PEARL POWDER. *Prep.* Drop a weak solution of common salt, or muriatic acid, into another of bismuth, prepared by dissolving that metal in twice its weight of nitric acid: collect the precipitate and wash it well with water. *Use.* As a cosmetic. Both this article and the subnitrate have received the name of pearl powder, from their extreme beauty and whiteness.

BISMUTH, SUBNITRATE OF. *Syn.* TRISNITRATE OF BISMUTH, (P. L.) WHITE BISMUTH, (P. E.) PEARL-WHITE. MAGISTERY OF BISMUTH. FARD'S SPANISH WHITE. BLANC DE FARD. (*Fr.*) *Prep.* (*Process of the London Ph.*) Dissolve ℥ij of bismuth in f℥iij of nitric acid, previously diluted with f℥ij of distilled water; then add 3 quarts of cold water, and allow the white precipitate to subside. Afterwards decant the clear liquor, wash the powder, and dry it by a gentle heat.

Remarks. The processes of the Dublin and Edinburgh Pharmacopœias are similar. Geiseler has ascertained by comparative experiment that the product is greater, if, according to Duflos, the nitrate of bismuth be allowed to crystallize previously to dilution with water, than if the dilution be executed at once. The proportion of the proceeds was as 10½ to 14, the quality of both preparations being alike. (Ph. C. Bl., Dec. 1842.)

Prop. A white inodorous powder, insoluble in water, but freely so in nitric acid. *Use.* It has been given in some chronic stomach complaints in doses of 5 to 20 grs. and upwards. An ointment formed with 1 part of this substance and 4 parts of lard, has been long in use as a remedy in some chronic skin diseases. Used by the ladies as a cosmetic.

BISMUTH, SULPHURET OF. This is a natural production, but may be prepared artificially by fusing its elements together, or by passing sulphureted hydrogen through a solution of nitrate of bismuth.

BISTRE. A dark brown-colored pigment, used for water-color drawings, after the style of Indian ink. *Prep.* This color is made from the soot of beech-wood, or peat, the former being preferred. The most compact, best colored, and well burnt parcels of the soot are selected from the chimney, reduced to a fine powder, and sifted through a very fine lawn sieve. This powder is then digested in pure cold water for several hours, frequently stirring it up during the time with a rod of glass or wood, after which it is allowed to settle, and the clear water decanted. More water is then poured on, and the process repeated a second, and even a third time. The paste is now poured into a tall narrow vessel, which is then filled up with water, and well agitated; after which the grosser parts are allowed to subside for 2 or 3 minutes, and the supernatant liquor, containing the finer portion of the bistre in suspension, is poured off into another vessel, where it is left to deposite its contents. For very fine bistre, this process is generally repeated a second time. The powder deposited in the last vessel is now collected and partially dried, when gum-water is added, and it is made into cakes and finally dried for use.

Remarks. Bistre is esteemed by artists as superior to Indian ink, for drawings which are intended to be afterwards tinted with other colors. It occupies the same place in water colors that brown pink does in oil painting.

BITES AND STINGS OF INSECTS, REPTILES, &c. *Treat., &c.* The best treatment for the bites and stings of insects, as bees, wasps, hornets, &c., is to wash the part with water of ammonia, or solution of chloride of lime. Should considerable inflammation ensue, and the part become much swollen, leeches may be applied, and a purgative given. The stings of venomous reptiles may be similarly treated, except in cases where they are of a very poisonous description, when the wound should be first well washed with water of ammonia, and afterwards thoroughly seared with lunar caustic in every part, especially the interior and deep-seated portions; or the surface of the wound, both internal and external, may be removed with the knife, or in the case of a small joint, as a finger, the injured portion may be at once amputated. A similar line of treatment should be followed after the bite of a dog supposed to be mad. It has been lately asserted by one of our most celebrated veterinary surgeons, that both he and his colleague have been repeatedly bitten by dogs that have afterwards been proved to be mad, but from having fearlessly applied the caustic to the parts, they have escaped uninjured.

The poison inserted by the stings and bites of many venomous reptiles, is so rapidly absorbed, and of so fatal a description, as frequently to occasion death within a very short space of time, and before any remedy or antidote can be applied. But even in these extreme cases, it is probable that strong liquid ammonia, or solution of chloride of lime, or bichloride of mercury, if at hand, and applied to every portion of the wound, *immediately after* its infliction, would neutralize and destroy the dangerous action of the poison. Unfortunately, however, these wounds are inflicted in parts of the world where precautionary measures are seldom thought of, and generally at times when people are least prepared to meet them, and so suddenly and unexpectedly, as to stagger even those observers who may be in no absolute danger themselves. Such is the bite of the East Indian copra de capello, against which two Carnatic, or Asiatic (arsenical) pills are prescribed by the Hindoos, but which are generally scarcely swallowed, before the poison of the serpent has rendered the patient a stiffened corpse. In all cases of this emergent kind, the remedy must be either one to be applied to the wound, to neutralize the poison before it can be absorbed into the blood, or one that will at once mingle with the circulation, and destroy its action, if already introduced into the system. Medicines taken by the mouth are slow in their action, and require some time to enter into and mix up with the whole mass of blood. When the venom of a rabid dog, or of the more poisonous snakes, is once *fully absorbed into the system*, there appears to be no treatment that can save the patient. A bottle of Madeira wine, drunk in two doses, about 3 minutes apart, has been recommended against the latter, and is perhaps as likely to prove beneficial as any thing else.

BITTERN. *Prep.* A mixture of 1 part each, of extract of quassia and powdered sulphate of

iron, with 2 parts of extract of cocculus indicus, 4 parts of Spanish liquorice, and 8 of treacle. The liquorice is first boiled with water until dissolved, and evaporated to a proper consistence before adding the other ingredients. *Remarks.* This mixture is made by the brewers' druggists, and sent out in casks, disguised, to escape detection. It is employed by the fraudulent brewer to impart a false bitter and strength to his liquor.

BITTERS. Bitters are considered as tonic and stomachic, and to improve the appetite when taken in moderation. The best time is early in the morning, or an hour before meals. An excessive use of bitters tends to weaken the stomach. They should not be taken for a longer period than a fortnight at *one time*, allowing a similar period to elapse before again having recourse to them.

BITTERS, BRANDY. *Syn.* Spirit Bitters. *Prep.* I. Dried orange and lemon peel, of each 2 oz.; fresh ditto, of each 3 oz.; good brandy 1 gallon; lump sugar 1 lb. *Proc.* Digest the peel in the brandy for 10 days, frequently shaking; then press out the liquor and filter through blotting paper; lastly, dissolve the sugar therein. *Remarks.* A very agreeable bitter, either taken as a dram, or mixed with other liquor.

II. Gentian root, bruised, 4 oz.; fresh orange peel 5 oz.; cassia bark 2 oz.; cardamom seeds, bruised, 1 oz.; cochineal, bruised, ½ oz.; proof spirit 1 gallon. *Proc.* Digest for a week, then decant the clear, press the bottoms, and pour thereon 5 pints of water; again digest for 3 days, then press out the liquor, mix the two tinctures, filter and add sugar 2 lbs.

III. Bruised gentian 2 oz.; fresh orange peel 3 oz.; cassia bark ½ oz.; cloves 1 drachm; proof spirit 1 gallon; cape or raisin wine ½ gallon; digest for a week as before, then add sugar 1 lb., and a little coloring, if required.

IV. Bruised gentian ¼ lb.; cochineal ¼ oz.; sugar ¾ lb.; spirit (24 u. p.) 1 gallon.

BITTERS, CALOMBA. *Prep.* Calomba root, fresh orange and lemon peel, of each 1 oz.; proof spirit 1 quart; digest for a week, then express the tincture, add lump sugar 4 oz., and a little coloring.

BITTERS, WINE. I. *Ing.* Bruised gentian root, fresh orange and lemon peel, of each 1½ oz.; white wine 1 quart; digest for a week, and strain.

II. (M. Dubois.) Cinchona bark, bruised, 8 oz.; white canella 1½ oz.; juniper berries, lemon peel, and winter's bark, of each 1½ oz.; carbonate of soda ½ oz.; Madeira wine 1½ gallons; digest for a week.

III. Fresh lemon peel 1 lb.; dried orange peel ½ lb.; bruised gentian root ¼ lb.; cape wine 1 gallon; as before.

Use. As a tonic and stomachic.

BLACK ASH. The waste lye of the soapmakers, evaporated in large iron boilers, the salt separated as it falls down, and then heated in a reverberatory furnace until it is partially decomposed and fused, when it is run into iron pots to cool. *Use.* It is used in the manufacture of common soap and alum.

BLACK, BEECH. *Syn.* Vegetable Blue Black. Made by burning beech-wood in close vessels, and well washing and igniting the charcoal with water. Used as a pigment.

BLACK, BONE. *Syn.* Animal Charcoal. The residuum of the distillation of bone spirit. *Use.* As a pigment; for making blacking; as a material for the moulds of founders; for clarifying and bleaching liquids, and for removing lime from sirup in refining sugar. Sold for ivory-black.

BLACK, (FINE,) BONE. *Syn.* Paris Black. Turners' bone-dust, burnt with great care in covered iron crucibles, and afterwards ground very fine. *Use.* A beautiful black, works well both in oil and water; sold for real ivory-black, and for burnt lamp-black.

BLACK, BRUNSWICK. *Prep.* Melt with care 2 lbs. of asphaltum in an iron pot, then stir in 1 pint of hot boiled oil, mix well, remove the pot from the fire, and when cooled a little, add 2 quarts of oil of turpentine. *Use.* To blacken and polish grates and ironwork.

BLACK, BURNT LAMP. Lamp-black heated in a covered iron crucible until all its greasiness is burnt off. *Use.* As a water-color. Paris black is usually sold for it.

BLACK, COMPOSITI: N. *Syn.* Prussian Black. The residuum of the process of making prussiate of potash from blood and hoofs. *Use.* As a pigment, and instead of bone-black, than which it decolors better.

BLACK DYE. I. (For Cotton and Linen.) *Proc. a.* Steep the goods, previously dyed blue, for 24 hours in a decoction of gall nuts or sumach, then withdraw them, rinse them well in water, and pass them through a bath of acetate of iron for a quarter of an hour; again rinse and air them, then pass them a second time through the bath, to which a little more iron liquor must be added. The whole process may be repeated as often as necessary.

b. Steep the goods in a mordant of acetate of iron, working them well, then pass them through a bath of madder and logwood for 2 hours.

Remarks. About 2 oz. of coarsely powdered galls, or 4 oz. of sumach, are required for every pound of cotton, in the process of galling. The former should be boiled in water, in the proportion of about 3 or 4 pints of water to every pound of cotton, but the sumach bath is better made by mere infusion in very hot water. For a very superior black the stuff must be first dyed blue, as before mentioned.

II. (*For Silk.*) Silks are dyed much in the same way as woollens, but the process is conducted with less heat, and the richness of the dye may be varied at pleasure, by allowing the goods to remain a longer or shorter time in the bath.

Proc. a. Give the silk a bath of gall nuts for from 12 to 40 hours, occasionally working it therein, then take it out, rinse and air it, and run it through a bath containing a little sulphate of iron, for a few minutes; again rinse and air it. The whole operation may then be repeated until the proper depth of color is obtained.

b. Boil 22 lbs. of Aleppo galls, bruised, for 1 hour in 2 hogsheads of water, then add 32 lbs. of copperas, 14 lbs. of iron filings, and 22 lbs. of gum; digest for 1 hour, and when the ingredients are dissolved, pass the silk, previously galled with ¾ of its weight of galls, through the bath for 1

hour, then rinse and air it well; next leave it in the dye bath for from 6 to 12 hours, and again repeat the whole process as often as necessary. The above ingredients are for 1 cwt. of silk.

III (*For Wool.*) Wool and woollen goods are usually dyed blue, preparatory to undergoing the process of being dyed black, as not only is the color thus rendered fuller and finer than it would otherwise be, but also more durable. When the goods are coarse or common, and the price is an object, they are generally "*rooted*" instead of being "*blued.*" This consists in giving them a dun or brown color, with the husks of walnuts, or the roots of the walnut tree. The goods being thus prepared are ready to receive the dye.

Proc. a. Twenty lbs. of logwood chips and 18 lbs. of galls, reduced to a rough powder, are enclosed in a coarse bag, and placed in a suitable sized boiler, where they are boiled with water for 8 or 10 hours; ⅓ of this decoction is then transferred into another copper, with 2 lbs. of verdigris and a sufficient quantity of water. and the goods passed through it for two hours, at a heat but little below boiling. The goods are next drained out, and another ⅓ of the decoction of logwood and galls, and 9 lbs. of copperas added to the boiler; the fire is then lowered, and as soon as the copperas is dissolved, the cloth is again introduced and worked through it well for 1 hour; it is then taken out and aired, and the remaining third of the decoction added, with about 20 lbs. of sumach; the whole is then brought to a boil, and 2 pounds more sulphate of iron added, with a pailful of cold water, after which the goods are put in a third time, and worked for 1 hour; they must then be taken out, washed and aired, and again passed through the bath for an hour. The stuff is now thoroughly rinsed, until the water comes off clean, when it may be dried at once, or further softened and beautified by putting it, for a quarter of an hour, through a hot bath of weld, but not boiling, after which it must be again rinsed. *Remarks.* The above proportions are for 1 cwt. to 1½ cwt. of wool or stuff, and forms a beautiful though expensive dye. The following are simpler and cheaper methods.

b. Make a bath as before with 2 lbs. of fustic, 4½ lbs. of logwood, and 11 lbs. of sumach; boil the cloth therein for 3 hours, then lift it out and add 11 lbs. of sulphate of iron, and when dissolved pass the cloth through it during 2 hours. Next rinse and air the cloth, and again pass it through the bath for 1 hour; lastly, rinse until the water runs clear.

c. Make a bath as before, with 4 oz. of bruised galls, and 1½ lbs. of logwood chips; boil your goods therein for 2 hours, then take them out, and add 4 oz. of green copperas, and when it is dissolved, pass your goods through it for 2 hours, keeping the bath very hot, but not boiling; again take them out, wash and air them well, add 1 oz. more of copperas to the bath, and pass the cloth through it for another hour; lastly, well rinse it. This method is suited to dyeing in the small way in private families. The above ingredients are sufficient for 7 or 8 lbs. of woollen goods, if well managed.

Remarks. In the process of dyeing black, especially on wool, it is necessary to take it out several times, and expose it to the air; this is called "*airing,*" and is done to allow the oxygen of the atmosphere to act upon the dye, without which a good color cannot be produced. The usual proportions employed by the dyers of England are, 5 lbs. each of galls and copperas, and 30 lbs. of logwood for every cwt. of cloth, but these weights are often increased for choice goods.

BLACK DRAUGHT. *Syn.* COMPOUND SENNA MIXTURE.

Prep. I. Infusion of senna f℥xivss.; tincture of senna f℥iss.; epsom salts ℥iv.; carbonate of ammonia ℈j; mix. (U. H.)

II. Senna 13 oz.; boiling water 2 quarts; digest for 4 hours in a hot place, then press out the liquor in a tincture press, and add ¾ of a pint of tincture of senna (co.) and 1 lb. of epsom salts.

III. East India senna 2 lbs.; boiling water 9 quarts; tincture of senna and epsom salts, of each 3½ lbs.; as last.

IV. Senna 8 lbs.; boiling water 9 gallons; epsom salts 16 lbs.; tincture of senna 1½ gallons; treacle and coloring, of each, 1 quart.

V. As last, but instead of tincture of senna, use 3 quarts of spirits of wine and 2 quarts of water.

Remarks. As the above mixture contains but little spirit, and from its great consumption, being made in large quantities, it frequently spoils before the whole is sold, especially in hot weather. To avoid this, 1 drachm of cloves and 2 drachms of mustard seed, both bruised, may be added to every gallon of the strained liquor at the same time with the salts, spirit, and coloring, after which it must be shaken up repeatedly for a few days, and then allowed to repose for a few days more, when it will become as clear as brandy. If wanted immediately it may be at once filtered through a flannel bag.

BLACK, FLOREY. *Syn.* FLOREE D'INDE. The dried scum of the dyer's woad bath. It makes a superior blue-black.

BLACK, FRANKFORT. Vine branches, lees of wine, &c., calcined in covered vessels, and then well washed and ground. *Use.* As a pigment, and to make printer's ink.

BLACK, FROM WINE LEES AND TARTAR. This pigment is prepared by calcination in cylindrical iron pots, furnished with covers, in the centre of which is left a small hole for the escape of the fumes and vapors. When smoke ceases to be evolved, the process is concluded, and after cooling, the whole is well washed and ground fine. *Use.* Similar to Frankfort black.

BLACK, HARTSHORN. Prepared by calcining the residuum of the distillation of spirits of hartshorn. Similar to ivory and bone black.

BLACKING, (FOR DRESS BOOTS AND SHOES.) *Prep.* I. Gum arabic 4 oz.; treacle or moist sugar 1 oz.; ink ½ pint; vinegar and spirit of wine, of each, 1 oz. *Proc.* Dissolve the gum and treacle in the ink and vinegar, then strain and add the spirit.

II. To the above add 1 oz. of sweet oil, and ½ oz. of lamp-black.

III. Beat well together the whites of two eggs, a tablespoonful of spirit of wine, a lump of sugar, and a little finely-powdered ivory-black to thicken.

Remarks. The first two articles are applied to the leather by the tip of the finger or a sponge, and allowed to dry out of the dust, and are only adapted for clean, dry weather, or indoors. The last is laid on and polished with a brush, and then left for a few hours to harden. It may also be used to revive the faded black leather seats and backs of old chairs. All of these possess great brilliancy for a time.

BLACKING, (FOR HARNESS, &c.) *Prep.* Melt 2 oz. of mutton suet with 6 oz. of bees'-wax; add 6 oz. of sugar-candy, 2 oz. of soft soap dissolved in water, and 1 oz. of indigo finely powdered; when melted and well mixed, add a gill of turpentine. Lay it on the harness with a sponge, and polish off with a brush.

BLACKING, (FOR BOOTS AND SHOES.)

I. (*Liquid.*) *Prep. a.* Ivory-black, in fine powder, 1 lb.; treacle ¾ lb.; sweet oil 2 oz.; beer and vinegar, of each, 1 pint. *Proc.* Rub together the first three until the oil be perfectly "*killed*," then add the beer and vinegar.

b. Ivory-black and treacle, of each 1 lb.; sweet oil and oil of vitriol, of each ¼ lb. *Proc.* Mix the first three as before, then gradually add the vitriol, diluted with thrice its weight of water; mix well, and let it stand for 3 hours, when it may be reduced to a proper consistence with water or sour beer.

c. Ivory-black and treacle, of each ½ lb; oil of vitriol 1 oz.; sweet oil 2 oz.; sour beer 1 pint; as above.

d. Ivory-black 7 lbs.; treacle 6 lbs.; sweet oil 1 lb.; oil of vitriol ½ lb.; water q. s., as last.

e. Ivory-black 3 cwt.; crude molasses 2 cwt.; linseed oil 3 gallons; oil of vitriol 20 lbs.; water q. s., as last.

II. (*Paste.*) *Prep. a.* Treacle 1 lb.; ivory-black 1½ lbs.; sweet oil 2 oz.; rub together as before, then add a little lemon juice or strong vinegar.

b. Ivory-black 2 lbs.; treacle 1 lb.; olive oil and oil of vitriol, of each ¼ lb.; water q. s., as before.

c. Ivory-black 28 lbs.; treacle 21 lbs.; common oil 1 quart; oil of vitriol 3 lbs.; water q. s.

d. Ivory-black 3 cwt.; common treacle 2 cwt.; linseed oil and vinegar bottoms, of each 3 gallons; oil of vitriol ¼ cwt.; water q. s.

Remarks. The manipulations required for paste and liquid blacking are the same, the difference in the two being the quantity of liquid added. Thus, by diluting paste blacking with water or beer bottoms, it may be converted into liquid blacking of a similar quality, and, by using less fluid matter, the ingredients of liquid blacking will produce paste blacking. One thing must, however, be observed, and that is, that the ivory-black used for liquid blacking must be reduced to a much finer powder than for paste blacking, as, if this be not attended to, it will settle to the bottom, and be with difficulty diffused again through the liquid. For those persons who do not like the use of blacking containing oil of vitriol, the first of the above forms, either for paste or liquid, may be adopted. The vitriol, however, greatly contributes to promote the shining properties of the blacking, and in small quantities is not so injurious to the leather as has been falsely represented, as it wholly unites itself to the lime of the phosphate contained in the ivory-black, and is thus partly neutralized. This is the reason why *lamp-black* should *never* be employed for blacking, as it has no earthy base to absorb or neutralize the acid, which would then prove very hurtful to the leather. Oil of vitriol is now employed in the manufacture of all the most celebrated shining blackings. The addition of white of eggs, isinglass, gum arabic, and similar articles to blacking, always proves injurious, as they tend to stiffen the leather and to make it crack.

BLACK, JAPAN. *Syn.* BITUMINOUS VARNISH. *Prep.* Fuse by a gentle heat 12 oz. of amber, and 2 oz. of asphaltum, then add 2 oz. of black rosin, and ½ a pint of boiled oil; mix well, remove it from the fire, and when nearly cold, add ¾ pint of spirit of turpentine; mix well together. *Use.* To varnish metals.

BLACK, IVORY. *Syn.* COLOGNE BLACK. CASSEL BLACK. *Prep.* Put into a crucible, surrounded by burning coals, fragments or turnings of ivory, or of the osseous parts of animals, and cover it closely. The ivory or bones, by exposure to the heat, will be reduced to charcoal. When no more smoke is seen to pass through the joining of the cover, leave the crucible over the fire for half an hour longer, or until it has completely cooled. There will then be found in it a hard carbonaceous matter, which must be pounded and ground on porphyry with water, washed on a filter with warm water, and dried. Before it is used it must be again subjected to grinding. *Remarks.* Black furnished by bones is reddish. That produced by ivory is more beautiful. It is brighter than black obtained from peach stones. When mixed in a proper dose with whitelead, it forms a beautiful pearl gray. Ivory-black has a very deep and rich color. The Cologne and Cassel blacks are formed from ivory.

BLACK, LAMP. *Prep.* I. Suspend over a lamp a conical funnel of tin plate, having above it a pipe to convey from the apartment the smoke which escapes from the lamp. Large mushrooms, of a very black carbonaceous matter, and exceedingly light, will be formed at the summit of the cone. This carbon is reduced to such a state of division, as cannot be given to any other matter, by grinding it on a piece of porphyry. This black goes a great way in every kind of painting. It may be rendered less oily and drier by calcination in close vessels.

The funnel should be united to the pipe, which conveys off the smoke, by means of wire, because solder would be melted by the flame of the lamp.

II. This article was originally prepared by burning oil in lamps and collecting the soot in a funnel inverted over it, as above described. Hence the name. It is now, however, generally made on the commercial scale, by burning the oil of bones or common coal tar, previously freed from its ammonia, and receiving the smoke in a suitable chamber. In the patent process of Messrs. Martin and Grafton, the coal tar is violently agitated with lime water, until the two are well mixed, after which it is allowed to subside, and the lime water being drawn off, it is washed several times with hot water. After the whole of the water has been removed by subsidence and decantation, it is put into stills, and heat applied until the impurities have passed over, and the spirit runs clear and smooth. The receiver is then charged, and the heat raised sufficiently high to drive over the whole of the oil

and spirit, leaving only the asphaltum in the still. The tar or liquor in the receiver is then put into a long cast-iron tube, furnished with numerous large burners, underneath which is a furnace to heat the pipe to nearly the boiling point. Over each burner is a sort of funnel, which goes into a cast-iron pipe or main, and which receives the smoke in a similar way from all the burners. From this the smoke is conveyed by large pipes to a box, where the heaviest part of the black is deposited; from this it is carried by pipes to a second box, where another deposite takes place, and from this box the pipe is continued until it passes into a series of large canvass bags, arranged side-by-side, and connected together at top and bottom alternately. Fifty or eighty of these bags are employed, the last one being left open to admit of the escape of the smoke, which has thus been made to traverse a space of about 400 yards. As soon as the bags contain any considerable quantity of black, they are removed and emptied. The black deposited in the last bag is the finest and best, and it becomes progressively coarser as it approaches the furnace.

BLACKLEAD. *Syn.* Plumbago. Carburet of Iron? *Qual. Use, &c.* The best blacklead comes from Cumberland, and is used for making pencils for artists. The coarser sorts are employed to impart a metallic lustre to other bodies, and mixed with grease to diminish friction. Blacklead is also used to cover the face of articles on which it is desired to deposite a coating of copper by the electrotype. It has been used in herpes, and some chronic skin diseases, in the form of an ointment, made with 4 times its weight of lard.

BLACK, PEACHSTONE. The stones or kernels of peaches, cherries, and other similar kinds of fruit, burned in close vessels, then ground and washed well. *Use.* It works well with oil; mixed with white lead and oil it makes old gray.

BLACK, PITCOAL. The best coal for this purpose is that which has a shining fracture. It affords, perhaps, the most useful brown the artist can place on his palette; being remarkably clear, not so warm as Vandyke-brown, and serving as a shadow for blues, reds, or yellows, when glazed over them. It seems almost certain that Titian made large use of this material. Coal, when burned to a white heat, then quenched in water, and ground down, gives an excellent blue-black.

BLACK REVIVER. *Syn.* Paris's Anticardium. *Prep.* I. Blue galls, bruised, 4 oz.; logwood, copperas, iron filings, and sumach, of each 1 oz.; vinegar 1 quart. *Proc.* Macerate in a close vessel, with heat, for 24 hours, then strain off the clear, add the filings and copperas, and shake it occasionally for a week. Keep it in a corked bottle.

II. Bruised blue galls 1½ lbs.; logwood ½ lb.; copperas 6 oz.; vinegar 1 quart; water 3 quarts. As above.

III. Galls 1 lb.; logwood 2 lbs.; copperas ½ lb.; boil for 2 hours in water 5 quarts, until reduced to a gallon, and strain. *Use.* To restore the color of black cloth.

BLACK, RUSSIAN. *Syn.* Russian Lamp-Black. Prepared by burning the chips of resinous deals, and collecting the black matter deposited by the smoke. It is a good black pigment, but apt to take fire spontaneously if left for some time moistened with oil.

BLACK, RICE. Prepared by burning rice in close vessels. The color is very poor.

BLACK, SPANISH. *Syn.* Cork Black. Cork burnt in close vessels, and the charcoal ground and washed with water. A good color, and works very soft.

BLACK, SOOT. The soot of coal fires, ground and sifted. Used as a common paint; mixed with Venetian red and oil, it makes a chocolate color; also used to make gray mortar.

BLACK, SUGAR. *Syn.* Jamaica Black. Prepared by burning sugar in close vessels. It works free, but is deficient in body. It is a warm color for washing drawings, and equal in mellowness to Indian ink and bistre.

BLACK, VINE TWIG. *Prep.* From vine twigs, by calcination as above. With whitelead and oil it produces beautiful shades of silver gray and white.

BLACK, WHEAT. From wheat burnt in close vessels. *Remarks.* A superior black, between ivory and lamp-black; it has a full body and dries hard and quickly with oil.

BLADDERS. *Prep. &c.* These articles are prepared by cutting off the fat and loose membranes attached to them, and washing them first in a weak solution of chloride of lime, and afterwards in clear water; they are then blown out and submitted to pressure by rolling them under the arm, by which they become considerably larger; they are next blown quite tight, dried, and tied up in dozens for sale. *Use.* Employed by druggists and oil and colormen to tie over pots, bottles, and jars, and to contain pill masses, and other similar substances. *Caution.* Never buy bladders unless they are perfectly dry and tight, as, if the reverse be the case, they will neither keep nor prove sound.

BLANCHING OR WHITENING. An operation in cookery, performed by putting tongues, palates, meat, &c., into cold water, when it is gradually brought to boil, and the article taken out and plunged into cold water, where it is left until quite cold. It is intended to impart whiteness, plumpness, and softness.

BLANC, (in Cookery.) A compound, formed by mixing 1 lb. of grated bacon, 1 lb. of suet, ½ lb. of butter, 2 lemons, 3 or 4 carrots cut into dice, 3 or 4 onions, and a little water, and boiling them until done.

BLANCMANGE, (in Cookery.) Jelly, seasoned and made up into forms. *Prep.* I. Isinglass 1 oz.; sweet almonds, 12 in no.; bitter do. 6 in no.; milk 1 quart. *Proc.* Boil the isinglass and almonds grated in the milk, until of a proper consistence when cold; then strain it, and when nearly cold pour it into the moulds, previously rubbed with a little salad oil, and then wiped out again.

II. To the above add ½ lb. of lump sugar and 4 tablespoonfuls of cream; when cold, remelt it and add a tablespoonful of orange flower water, after which it may be moulded as before.

III. Use calves' feet jelly instead of isinglass.

IV. (Mrs. Hoffman's.) Isinglass ¼ lb.; rosewater ½ pint; milk 2 quarts; milk of almonds ½ pint.

V. (*Rice.*) Ground rice 2 oz.; milk 1 pint; lump sugar 3 oz.; a little lemon peel and cinnamon; dissolve the rice in the milk by boiling; reduce it to a

proper consistence, then add the spice and sugar, boil for 1 minute, and strain, and when nearly cold mould as above. *Caution.* The powdered rice must be rubbed up with a little cold water previously to adding it to the milk, to prevent it running into lumps.

VI. (*West Indian.*) Make a jelly with arrowroot, and to every pint, when nearly cold, add a glass of sherry, a spoonful each of brandy and orange flower water, and 2 oz. of lump sugar.

VII. (*Transparent.*) Instead of milk use water, and clarify with the white of an egg.

BLANQUENINE. A name given by Dr. Mills to a new vegetable alkali, which he thought he had discovered in white cinchona bark. (Quar. Jour. Science, Ap. 1828.)

BLANQUETTE, (IN COOKERY.) A sort of white fricasee.

BLEACHING. *Syn.* BLANCHISSAGE. (*Fr.*) BLEICHEN. (*Ger.*) The operation by which the natural colors of substances are discharged, and they become white or colorless. Bleaching may be performed either by natural means, as exposure to light, air, and moisture, or by chemical agents, as chlorine, chloride of lime, sulphurous acid, &c. In many of the processes adopted for this purpose, both methods are combined. The most important application of the art of bleaching in the United Kingdom, is in the manufacture of textile fabrics. The celerity with which this is performed in the most perfect manner, and the trifling expense thereby incurred, contribute, in no small degree, towards inducing that preference universally shown to the productions of the looms of Great Britain.

COTTON, from its original whiteness, and little attraction for coloring matter, is more easily bleached than most other substances. On the old plan, it is first well washed in warm water to remove the weaver's paste or dressing, then "*bucked*" (boiled) in a weak alkaline lye, and after being well washed is spread out upon the grass, or bleaching ground, and freely exposed to the joint action of light, air, and moisture. The operation of "*bucking*" and exposure is repeated as often as necessary, when the goods are "*soured*" or immersed in water acidulated with sulphuric acid, after which they receive a thorough washing in clean water, and are dried. From the length of the exposure upon the bleaching ground, this method has been found to injure the texture of the cloth, and from the number of operations required, necessarily becomes expensive, and produces considerable delay; it has therefore very generally given place to the improved system of chemical bleaching, by means of chloride of lime. In this method, after the first operation of washing and bucking, as in the common process, the cotton is submitted to the action of weak solutions of chloride of lime, and afterwards passed through soured water, when it has only to be thoroughly washed and dried.

LINEN is bleached in a similar way to cotton, but the operation is more troublesome, from its greater affinity for coloring matter.

WOOL is first exposed to the joint action of fuller's earth and soap, in the fulling mill, to remove adherent grease and dirt, and is then well washed and dried, when it is usually found sufficiently white for the purposes of the dyer; but should the slight yellow tint it retains prove objectionable, it is run through water tinged blue with indigo, or it is exposed to the fumes of burning sulphur; the latter method gives it a harsh feel, which is best removed by a bath of soap and water, but this will reproduce its previous yellowishness.

SILK is bleached by boiling it in white soap and water, to remove the natural yellow varnish that covers it, after which it is subjected to repeated rinsings. Articles that are required to be very white, as gloves, stockings, &c., are also submitted to the action of sulphurous acid, or the fumes of burning sulphur.

STRAW is also bleached by the fumes of sulphur; hence arises the sulphurous smell emitted by new straw hats and bonnets. They may, however, be bleached in a much better manner by the use of a little oxalic acid, or chloride of lime.

OLD RAGS, for the manufacture of paper, and paper pulp, are generally bleached with chlorine.

PRINTED BOOKS, ENGRAVINGS, &c., may be whitened by first subjecting them to the action of weak chloride of lime water, next to water soured with sulphuric acid, and, lastly, to pure water, to remove any adhering acid or chlorine.

Remarks. The theoretical principles of bleaching are but little understood; it is thought to depend upon the action of oxygen, in a nascent state, on the particles of coloring matter, but this is unsupported by direct experiment. It is, however, an art eminently indebted to chemistry for its present efficiency, and is based on the practical application of facts which that science has called to light.

BLEEDING FROM THE NOSE. When this occurs under common circumstances, and without violence, it may be regarded as a natural effort to relieve the body from an excess of blood; but when it becomes habitual, or is the result of violence, remedial measures should be had recourse to. A simple means of arresting the hæmorrhage is to introduce, by means of a probe, a small piece of lint or soft cotton, previously dipped into some mild styptic, as a solution of alum, white vitriol, or creosote, or even cold water. This will generally succeed, but should it not, cold water may be snuffed up the nostrils, or a small piece of ice placed in the nose. Should the bleeding be very profuse, or persistent, medical advice should be had recourse to. I once saw a person (an innkeeper) lose his life in the course of a few days from a voluntary hæmorrhage from the nose, which it was found impossible to stop or lessen.

A plan has been lately proposed by Dr. Negrier, of Angiers, which, he says, is simple and certain. "It is preferable to the occlusion of the nostrils, as that is difficult to maintain, especially in sleep. During three years that, in numerous cases, he has tried this method, which is simply elevating the patient's arm, he has never found it to fail. After detailing several cases, he thus explains the rationale of the plan. When the person is standing with the arms at the side, the blood which escapes from the upper part of the arch of the aorta, takes two directions, viz., towards the head, and towards the arms, and that which goes to the head is almost equal in quantity to that which is received by both superior extremities. If, however, the individual who was formerly hanging his arms, raised them, the blood which was flowing horizon-

tally and without effort from the subclavian into the brachial arteries, must then ascend against the weight of the column of blood contained in the latter; and as there is nothing in the act of raising the arm to increase the force of the circulation, it follows, that part of the force formerly expended in sending the blood up the carotids, must now be subtracted, and added to that which drives it through the brachial arteries. This explanation may or may not be confirmed by experiments. The subject is worth investigation." (Archives générales de Médecine. June, 1842.)

BLENORRHŒA. An increased discharge of mucus from the urethra or vagina. *Treat.* Administer mild aperients and tonics. Cold bathing, and general habits of cleanliness, powerfully promote a cure.

BLIND, WRITING FOR THE. If an iron style or pencil, with a moderately fine point, be used to write with upon paper, and a little more pressure be employed than in using a common pen, characters will be produced which may easily be read by blind persons after a little practice, by passing their fingers over them, either on the side on which they were written, where they will appear in intaglio, or by reversing the paper, where they will appear in relief.

BLISTER, EXTEMPORANEOUS. I. A piece of lint dipped into vinegar of cantharides, and immediately after its application to the skin, covered over with a piece of strapping, to prevent evaporation, will speedily raise a blister.

II. Concentrated acetic acid, applied in the same way, will have a similar effect.

III. The following method, proposed by Dr. Darcq, is very simple and convenient: Into a flat watch-glass, pour from 8 to 10 drops of very concentrated ammonia; cover the liquid with a small piece of linen, of a rather less diameter than that of the glass, and slowly apply this little apparatus to the previously shaved skin. Keep the whole in its place by means of moderate pressure with the fingers.

As soon as a red ring, about 2 *centimetres* in breadth, is observed round the glass, it is certain that vesication is effected. Sometimes scarcely 30 seconds is necessary for obtaining this result. It remains only to remove the apparatus, to wash the part, and to tear away with a pair of nippers the epidermis, which comes off easily and in one piece.

The dressing is according to the object in view, —to the indications of the endermic method, for example. (Bull. de Thér. & Chem., No. L. 88.)

BLISTER, LIQUID. *Prep.* I. Spanish flies 2 oz.; boiling water 1 pint; spirits of wine 4 oz.; corrosive sublimate ¼ oz.; spirits of salts ½ oz. *Proc.* Digest the flies in the water, in a warm place, for 24 hours, then add the corrosive sublimate, dissolved in the spirits of wine, and lastly, the spirits of salts. It may either be strained, or used as it is.

II. Rectified spirit, and liquid ammonia, of each 2 oz.; oil of origanum 1 oz.; mix. Add finely powdered Spanish flies 1 oz.

III. Strongest blistering plaster 2 oz.; oil of turpentine 1 oz.; mix with a gentle heat.

IV. Linseed oil, resin cerate, and oil of turpentine, of each 2½ oz.; powdered flies 1 oz.; as above. *Use.* For horses and cattle.

16

BLISTER, PERPETUAL. A common blister, raised in the usual way, but instead of allowing the surface to heal up, after the discharge of the water, it is kept open by dressing it with savine or cantharides ointment.

BLISTERING TISSUE. Thin paper, or silk, spread over with a thin coat of alcoholic, acetic, or ethereal extract of Spanish flies.

BLOOD, BULLOCK'S. This article is employed for the clarification of wines and sirups; in the preparation of adhesive cements; coarse paint for out-door work; as a manure; as a bleaching powder; and for several other purposes. The blood of sheep, pigs, and bullocks, mixed with flour or oatmeal, and seasoning, is used as an aliment by the common people, but it is rather indigestible, and consequently cannot prove nourishing.

BLOOD, POWDERED. *Prep.* Dry the blood, by free exposure in thin layers to a current of air, at a heat under 125°, until it becomes sufficiently dry to powder. *Use.* For exportation to the colonies, where it is used in the sugar works. *Remarks.* Bullock's blood, dried at a temperature from 212° to 225°, and coarsely powdered, is much used by fraudulent dealers to adulterate musk.

BLOOD, SPITTING OF. (See Hæmoptysis.)

BLOOD, SPITTING OF. Popular Remedy for. *Prep.* Infusion of red roses 5½ oz.; sirup of poppies ½ oz.; diluted sulphuric acid 20 drops; mix. *Dose.* One or two tablespoonfuls four times a day.

BLOOM, ALMOND. *Prep.* Boil 1 oz. of ground Brazil wood in 3 pints of water, for 15 minutes, strain and add ¾ oz. of isinglass, ½ oz. of powdered cochineal, 1 oz. of alum, and ½ oz. of borax; boil again for 3 minutes, or until the whole is dissolved, and strain through a piece of fine cloth.

BLOWPIPE. An instrument by means of which the flame of a candle or lamp is directed upon any substance placed to receive it, which is thus subjected to an intense heat.

The hottest portion of the flame produced by the action of the blowpipe, is at the tip of the outer white flame, which has also the property of rapidly burning or oxidizing any substance placed in it, which is capable of such an action; hence it has been called the "*oxidizing flame.*" The interior blue flame has also been called the "*reducing flame,*" from the property it possesses of abstracting oxygen from most substances placed in it.

App. "The substance to be submitted to the action of the blowpipe, must be placed on a piece of charcoal, or in a small spoon of platina, gold, or silver; or, according to Saussure, a plate of cyanite may sometimes be used. Charcoal from the pine is to be preferred, which should be well ignited and dried, that it may not crack. The sides, not the ends, of the fibres must be used; otherwise the substance to be fused spreads about, and a round bead will not be formed. A small hole is to be made in the charcoal, which is best done by a slip of plate iron bent longitudinally. Into this hole the substance to be examined must be put, in very small quantity; if a very intense heat is to be used, it should not exceed the size of half a peppercorn.

"Metallic spoons are used when the substance to be examined is intended to be exposed to the action of heat only, and might undergo some change by immediate contact with the charcoal. When the spoon is used, the flame of the blowpipe should be directed to that part of it which contains the substance under examination, and not be immediately applied to the substance itself. The handle of the spoon may be inserted into a piece of charcoal; and if a very intense heat is required, the bowl of the spoon may be adapted to a hole in the charcoal. Small portions may be taken up by platina forceps. Salts and volatile substances are to be heated in a glass tube closed at one end, and enlarged according to circumstances, so as to form a small matrass."

When the behavior of the substance has been observed in this way, it is melted with various fluxes, as microcosmic salt, borax, &c., and their action examined, both in the interior and exterior flame, by which means its composition may be generally ascertained, by reference to any work on mineralogy.

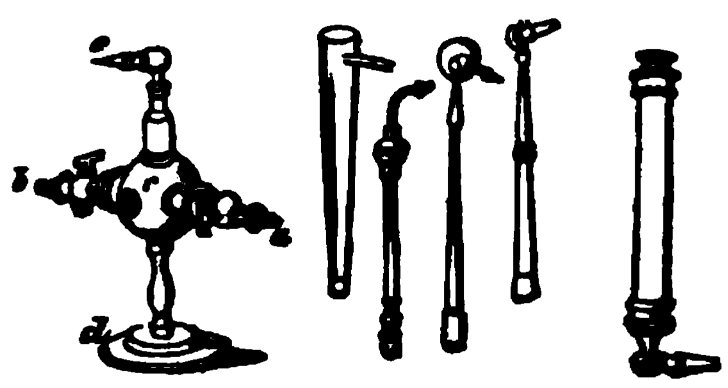
Beginners are usually unable to maintain a continual stream of air from the jet, which is, however, very simple to accomplish. The operation depends upon a little artifice in blowing through the pipe, which is in reality more difficult to describe than to acquire. "The effect intended to be produced is a continual stream of air for many minutes, if necessary, without ceasing. This is done by applying the tongue to the roof of the mouth, so as to interrupt the communication between the mouth and the passage of the nostrils; by which means the operator is at liberty to breathe through the nostrils, at the same time that by the muscles of the lips he forces a continual stream of air from the anterior part of the mouth through the blowpipe. When the mouth begins to be empty, it is replenished by the lungs in an instant, while the tongue is withdrawn from the roof of the mouth, and replaced again in the same manner as in pronouncing the monosyllable *tut*. In this way, the stream may be continued for a long time without any fatigue, if the flame be not urged too impetuously; and even in this case no other fatigue is felt than that of the muscles of the lips." (Ure.)

For producing extreme degrees of heat, the flame is blown with a jet of oxygen gas, and the instrument is then called an "*oxygen blowpipe;*" or a mixture of oxygen and hydrogen is burned, when it is called an "*oxy-hydrogen*" blowpipe. The heat produced by the last is so great that no substance can stand before it. The most refractory native compounds, as rock crystal, quartz, flint, chalk, plumbago, &c., are immediately fused. Gold is volatilized, and iron is rapidly consumed the instant it is placed in the flame. To use this wonderful instrument with safety, and to prevent an explosion, a peculiarly constructed jet is required. The principal blowpipes in general use are figured in the accompanying engravings. The shape of the common blowpipe adopted by the experimentalist may depend upon the fancy of its employer.

This apparatus is also furnished with valves and springs.

Beside the following there are several other va-

1 2 3 4 5 6



1, Oxy-hydrogen blowpipe.
2, Black's do.
3, Bergman's do.
4, Pepy's do.
5, Wollaston's do.
6, Hemming's safety jet for the oxy-hydrogen ditto.

a, Pipe conveying oxygen gas.
b, Do. do. hydrogen gas.
c, Ball stuffed with fine wire gauze.
e, Jet, (internal diameter 1-80th of an inch.)

rieties of blowpipes, in which the air is expelled by the pressure of a column of water, (hence called "*hydrostatic blowpipes,*") or the flame blown with the vapor of boiling alcohol, ("*spirit blowpipe.*")

Use. The blowpipe is of most extensive application in qualitative analysis, especially of minerals, and its use cannot be too highly recommended to the young chemist.

For further information on this subject the reader is referred to Gahn on the Blowpipe; to Ure's Dictionary of Chemistry; to Campbell's Translation of Kobell's Instructions for the Discrimination of Minerals; and to the Chemist, iv. 462.

BLUBBER. This substance, which is so plentiful on some parts of the coast of England, forms a very rich manure for pasture and arable land, when used at the rate of 1 ton to every 20 or 30 loads of mould, together with a chaldron of lime per acre. It must be well turned over, and after lying 3 or 4 months the land will be in prime condition.

BLUE, CHARCOAL. *Prep.* Triturate carbonized vine stalks with an equal weight of potash, then put it into a crucible and place it over the fire, until the mixture ceases to swell, keeping it well stirred all the time; next allow it to cool, dissolve it in water, and saturate the excess of alkali with dilute sulphuric acid; the liquid becomes blue, and a dark precipitate falls down, which turns of a brilliant blue color when dried and heated.

BLUE, COBALT. *Prep.* I. Dissolve Zaffre 1 lb. in ¾ lb. of nitric acid, diluted with an equal weight of water, by digestion for some hours, evaporate nearly to dryness, then dissolve in warm water, filter and add a solution of phosphate of soda as long as any precipitate falls down; collect this on a filter and wash it with cold water, then mix it while still moist with 8 times its weight of freshly precipitate hydrate of alumina, also well washed and still moist. Stir them together until dry; lastly, expose the mixture to a cherry red heat in a crucible, after which cool the mass, and reduce it to a fine powder.

II. Precipitate a solution of nitrate of cobalt as above, and proceed as before.

III. Make a strong solution of neutral nitrate

of cobalt, and mix it with pure moist alumina, then dry it and proceed as before.

IV. Precipitate a solution of nitrate of cobalt with ammonia alum, collect the precipitate, wash, dry, and heat it to a cherry red as before.

Use. A beautiful blue pigment, very permanent.

BLUE, CHEMIC. *Syn.* SAXON BLUE. LIQUID BLUE. SULPHATE OF INDIGO. *Prep.* I. Indigo 1 lb.; oil of vitriol 8 lbs. *Proc.* Put the acid into an earthenware pan, placed in a tub of water to keep it cool, and add the indigo, previously reduced to fine powder, in small successive portions, carefully stirring to prevent it *heating.* When all the indigo has been added, cover up the vessel and let it stand for 4 hours, occasionally stirring it during the time; lastly, dilute it with an equal weight of water.

II. Indigo 1 oz.; oil of vitriol 4 oz.; dissolve as before; the next day add 1 oz. of dry potash; let it stand a day longer, then dilute it with 12 oz. of water.

Use. In dyeing greens and blues, either without preparation or with a mordant of alum and tartar.

BLUE, CHINA. *Syn.* ROYAL SMALTS. *Prep.* Grind together oxide of cobalt or zaffre, with an equal weight of potash, and 8 times its weight of feldspar. Then submit the mixture to fusion in a crucible. *Use.* To paint pottery, and as a pigment.

BLUE, IRON. *Prep.* Precipitate a filtered solution of protosulphate of iron, with another of phosphate of soda. Collect the powder, wash and dry it. *Use.* A lively sky-blue.

BLUE, MOLYBDENUM. *Prep.* Dissolve sulphuret of molybdenum in nitric acid, then add some tin filings and a little muriatic acid. After digestion for some time, pour off the clear and evaporate to dryness. Mix the powder thus obtained with moist hydrate of alumina, as in making cobalt blue, and heat it to nearly a dull red.

BLUE, MOUNTAIN. Carbonate of copper, mixed with earthy matter.

BLUE, SAXON. *Prep.* Dissolve 1 oz. of sulphate of iron and 8 oz. of alum in 1 gallon of water, then add simultaneously, separate solutions of prussiate of potash and common pearlash, until they cease to produce a precipitate; lastly, allow the liquid to deposite, decant the clear portion, wash the remainder well with water, and dry it. Or a solution of the sulphate of iron may be first made and precipitated with the prussiate of potash, and instantly mixed with the solution of alum and a solution of pearlash, added until it ceases to produce a precipitate.

BLUE, SUPERB LIQUID. *Prep.* Put into a small matrass or common vial 1 oz. of pure Prussian blue reduced to powder, and pour over it from 1½ oz. to 2 oz. of concentrated muriatic acid. The mixture produces an effervescence and the prussiate soon assumes the consistence of thin paste. Leave it in this state for 24 hours, then dilute it with 8 or 9 oz. of water, and preserve the color thus diluted in a bottle well stopped.

The intensity of this color may be lessened, if necessary, by new doses of water. If the whole of this mixture be poured into 1 quart of water, it will still exhibit a color sufficiently dark for washing prints.

BLUE, STONE. *Syn.* FIG BLUE. THUMB BLUE. KNOB BLUE. CROWN BLUE. MECKLENBURG BLUE. QUEEN'S BLUE. *Prep.* Mix finely powdered indigo with starch paste until a proper color be produced, then make it into small lumps. II. Instead of starch use whiting and a little weak size. *Use.* Employed by laundresses to give a faint blue tinge to linen.

BLUE DYE. *Proc.* First give the goods a mordant of alum, then rinse them well and boil them in a bath of logwood, to which a small quantity of blue vitriol has been added.

II. Boil in a bath of logwood, then add 1 oz. each of tartar and verdigris to every pound of logwood employed, and boil again.

III. Bilberries, elder-berries, mulberries, privet-berries, and several other vegetable blue substances, may be used to dye blue as above instead of logwood.

Remarks. By increasing the proportion of alum the color verges on purple, and by employing a little acetate of iron or green copperas, the darker shades are produced. Verdigris, blue vitriol, and alkalis turn it more on the blue, and a mordant of tin imparts a violet cast. None of these dyes, however skilfully managed, are so permanent as those produced with indigo and Prussian blue. (See INDIGO, PRUSSIAN BLUE, and DYEING.)

BOARDS, MARBLE, &c., TO TAKE OIL AND GREASE OUT OF. I. Make a paste with fuller's earth and hot water, cover the spots therewith, let it dry on, and the next day scour it off with soft or yellow soap.

II. Make a paste with soft soap, fuller's earth, and a little pearlash, and use it as above.

III. Make a paste of fresh slaked lime, water, and pearlash, and use it as above. *Remarks.* Observe not to touch the last mixture with the finger, as it is very caustic unless it be largely diluted with water.

BOERHAAVE'S RULES FOR PRESERVING HEALTH.

"Keep the feet warm;
The head cool; and
The body open."

These rules are very concise, and convey directions which, though valuable, are too often neglected.

BOILING POINT. The boiling point of water may be raised considerably above 212° Fahr. by the addition of saline matter. Thus, 60 parts of dry acetate of soda added to 40 of water raise the boiling point to 256° Fahr., and 30 parts of muriate of soda added to 70 of water raise it to 224 Fahr. As in practice, however, it proves inconvenient to employ a saturated solution for a bath, from the evaporation of the water continually inducing the salt to crystallize, it is usual to keep it considerably below that point. By means of such solutions the chemist is enabled to evaporate fluids and desiccate solids at any required temperature. The boiling point of baths containing different salts may be seen below.

TABLE of the Boiling Points of several Saline Solutions, abridged from the Table of Mr. T. GRIFFITHS. (Jour. Science, xviii. 89.)

Names of Salts.	Dry Salt in 100.	Boiling Point.
Acetate of soda, . . .	60	256° F.
Nitrate of soda, . . .	60	246
Rochelle salt, ...	90	240
Nitre, ...	74	238
Muriate of ammonia, .	50	236
Tartrate of potash, . .	68	234
Muriate of soda, . . .	30	224
Ditto, ...	20	218·75
Muriate of lime, . . .	40	216·5
Sulphate of magnesia, .	57·5	222
Supersulphate of potash,	?	222
Borax, ...	52·5	222
Phosphate of soda, . .	?	222
Carbonate of soda, . .	?	220
Muriate of baryta, . .	45	220
Alum, ...	52	220
Sulphate of potash, . .	17·5	215
Bitartrate of potash, .	9·5	214
Sulphate of soda, . .	31·5	213

Remarks. From 5 to 9 degrees are usually lost by passing through the vessel, depending on its thickness and materials. The boiling point of water in glass vessels, under common circumstances, varies from 212·54° to 215·6°, and in perfectly pure and smooth glass vessels, water may be heated to 221° F. without boiling. (M. F. Marcet.)

BOILS. *Treat.* When these appear, suppuration should be promoted by poultices of bread and linseed meal, to which a little fat or oil may be added, to prevent their getting hard. When poultices are inconvenient, exposure to the vapor of hot water, or the application of stimulating plasters, may be adopted instead. When sufficiently ripe, the matter should be evacuated, and the wound dressed with a little simple ointment spread on a piece of clean lint or linen. The diet may be full and liberal until the maturation of the tumor and the discharge of the matter, when it should be lessened, and the bowels opened by some saline purgatives, as salts or cream of tartar. When there is a disposition in the constitution to the formation of boils, the bowels should be kept regular, and tonics, as bark or steel, taken, with the frequent use of sea-bathing, if possible.

BOLAS. *Prep.* Into 2 lbs. of flour pour ¾ pint of warm milk, a small teacupful of yeast, and 6 eggs; make them into a dough, add 1 lb. of butter, by degrees, and let it rise for 1 hour, then mix in 1 lb. of powdered sugar, and make the mass into cakes; put these into cups or tins previously well buttered, and ornament the top with candied orange or lemon peel; lastly, bake them.

BOLUS OF ALUM. *Prep.* Powdered alum and conserve roses, of each 15 grs.; sirup of orange peel or saffron to mix. *Used* in fluxes, &c.

BOLUS OF MUSK. *Prep.* I. Musk 15 grs.; camphor 5 grs.; powdered gum 3 grs.; mix with sirup of saffron. *Use.* In convulsions and typhus fever.

II. Musk and carbonate of ammonia of each 10 grs.; conserve of roses q. s.; to make a bolus. *Use.* Sometimes given every three hours in mortification accompanied with spasms.

BOLUS, PURGING, (FOR DOGS.) *Prep.* Jalap and rhubarb, of each 15 grs.; ginger 4 grs.; soap 10 grs.; water q. s.; if this does not open the bowels, add aloes half a drachm, or 3 or 4 grs. of calomel. *Use.* In the distemper; it must be preceded by copious bleeding, and abstinence from food for a day or a night.

BOLUS OF SULPHATE OF ZINC. *Prep.* Sulphate of zinc 20 to 25 grs.; conserve of roses q. s. to make a bolus. *Use.* As an emetic where poison has been taken, to be followed by copious draughts of warm water or weak tea.

BOLETIC ACID. An acid discovered by Braconnot in the juice of the boletus pseudo-igniarius.

Prep. Concentrate the expressed juice to a sirup by means of a gentle heat, then digest it in strong alcohol, and dissolve the residuum in water; add a solution of nitrate of lead as long as any precipitate falls, which must be washed with water, diffused through water in a tall glass vessel, and in this state a current of sulphureted hydrogen must be passed through it, until the lead is thrown down; filter, evaporate, and crystallize; lastly, purify by resolution and crystallization from alcohol.

Remarks. This acid dissolves in 45 parts of alcohol and 180 of water, and is volatile. It is doubtful whether it be a distinct acid principle.

BOLOGNA VIAL. The bologna, or philosophical vial, is a small vessel of glass which has been suddenly cooled, open at the upper end, and rounded at the bottom. It is made so thick at the bottom that it will bear a smart blow against a hard body without breaking; but if a little pebble, or piece of flint, is let fall into it, it immediately cracks, and the bottom falls into pieces; but unless the pebble or flint is large and angular enough to scratch the surface of the glass, it will not break.

BOLOGNIAN PHOSPHORUS. *Syn.* BOLOGNIAN STONE. This is a phosphorescent stone that once excited great attention. It was accidentally discovered by a shoemaker of Bologna in the 17th century. A family of the name of Logani, who were very successful in making it, acquired a large fortune by selling it to the curious throughout Europe.

Prep. Powder native sulphate of baryta that has been previously ignited, and make it into a paste with mucilage of gum arabic; roll this into pieces a quarter of an inch thick, and dry them in a moderate heat; then expose them to the heat of a wind furnace by placing them loose among the charcoal.

Prop., Use, &c. Placed in a vial and exposed for a few minutes to the sun's rays, it will give light enough in the dark to see the figures on the dial-plate of a watch.

BOMBIC ACID. An acid which M. Chaussier extracted from the silkworm in 1781. It has since been found not to be a distinct acid.

BON-BONS. *Prep.* Provide leaden moulds, which must be of various shapes, and be oiled with oil of sweet almonds. Take a quantity of brown-sugar sirup in the proportion to their size, in that state called a *blow,* which may be known by dipping the skimmer into the sugar, shaking it, and

blowing through the holes, when parts of light may be seen; add a drop of any esteemed essence. If the *bon-bons* are preferred white, when the sugar has cooled a little, stir it round the pan till it grains, and shines on the surface; then pour it into a funnel and fill the little moulds, when it will take a proper form and harden: as soon as it is cold take it from the moulds; dry it for two or three days, and put it upon paper. If the *bon-bons* are required to be colored, add the color just as the sugar is ready to be taken off the fire.

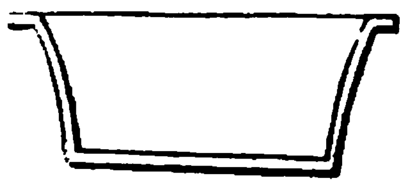
BONES. The bones of animals are employed for various purposes in the arts, manufactures, and domestic economy. (See the succeeding articles.)

BONE ASH. *Syn.* Impure Phosphate of Lime. *Prep.* Calcine bones to whiteness, and reduce the ash to fine powder. *Use.* To make pure phosphate of lime, and to form cupels. It is sold for burnt hartshorn.

BONE BLACK. *Syn.* Animal Charcoal. Ivory-Black. Bones burnt in close vessels.

Prep. On the large scale, two different processes are adopted to produce bone black.

I. (*From bones as the sole product.*) The bones broken to pieces are put into small cast-iron pots of the shape of the engraving, and varying from



$\frac{3}{8}$ to $\frac{1}{2}$ an inch in thickness. Two of these being filled, are dexterously placed with their mouths together and then luted with loam. A number of vessels, thus prepared, are placed side by side and over each other, in an oven resembling a potter's kiln, to the number of 100 to 150. The fire is then kindled, and the heat kept up strongly for 10 or 12 hours, according to circumstances, until the process is completed. The whole is allowed to cool before opening the pots.

II. (*The residuum of the manufacture of Bone Spirit.*) The bones are here introduced into retorts similar to those used at the gas works, and heat being applied, the volatile products are conveyed away by iron pipes to cisterns where its condensable portion is collected. As soon as the process of distillation is finished, the solid residuum in the retorts, while still red hot, is removed through their lower ends into wrought-iron canisters, which are instantly closed by air-tight covers, and luted over. These are then raised to the ground by a crane and allowed to cool.

Remarks. Previously to distillation or calcination, the bones are boiled for their grease, which is sold to the candle and soap makers. They are then sorted, the finest pieces being selected for making handles for knives, tooth-brushes, buttons, &c.; the next sort for making into bone black; while the smallest and worst description is reserved for grinding into manure. The bones lose about $\frac{1}{2}$ their weight by the process of burning. After this they are ground in a mill, sorted by sieves into two kinds, one *granular*, somewhat resembling gunpowder, and the other *quite fine*. The one is sold under the name of *animal charcoal*, for decoloring liquors, the other as a *pigment*. This article possesses the valuable property of taking lime from sirups, at the same time that it decolors them. Its power as a decolorizer may be tested by adding it to a solution of brown sugar or molasses, or water containing $\frac{1}{1000}$ part of indigo dissolved in sulphuric acid. The test should be made in a small glass tube. By well washing and careful reburning, this charcoal may be used any number of times as a decolorizer.

BONES AND IVORY, DYES FOR. 1. (*Red.*) *a.* Make an infusion of cochineal in water of ammonia, then immerse the pieces therein, having previously soaked them for a few minutes in very weak aquafortis and water.

b. Boil the bones with 1 lb. of Brazil dust, in 1 gallon of water, for 3 hours, then add $\frac{1}{4}$ lb. of alum and boil for 1 hour more.

2. (*Black.*) *a.* Immerse the pieces in a weak solution of nitrate of silver, for a short time, then expose them to the sunlight.

b. Steep for 2 or 3 days, in a decoction made with 1 lb. of galls and 2 lbs. of logwood, then steep for a few hours in iron liquor, (acetate of iron.)

3. (*Green.*) *a.* Steep in a solution of verdigris to which a little aquafortis has been added.

b. Dissolve distilled verdigris in weak vinegar, and steep the pieces therein.

c. Steep in a solution of 2 parts of verdigris, and 1 of sal ammoniac. *Observe* not to use a metallic vessel for the above.

4. (*Purple.*) *a.* Steep in a weak solution of terchloride of gold.

b. Boil for 6 hours in a decoction of 1 lb. of logwood in $\frac{1}{2}$ gallon of water, adding more water, as it wastes by boiling, then add 2 oz. of alum, and boil for 1 hour more.

5. (*Yellow.*) *a.* Boil for 1 hour in a solution made with 1 pound of alum in 1 gallon of water, then take out the pieces and steep them in a decoction made with $\frac{1}{2}$ lb. of turmeric in 2 quarts of water; lastly, mix the two liquors and boil them therein for 1 hour.

b. Steep the pieces for 24 hours in a solution of sugar of lead, then take them out, and when dry, immerse them in a solution of chromate of potassa.

c. Dissolve as much of the best orpiment in water of ammonia or hartshorn, as it will take up, then steep the pieces therein for twenty-four hours; lastly, take them out and dry them, when they will turn yellow. *Remark.* By diluting the solution with water, any shade of yellow may be made.

6. (*Blue.*) *a.* Stain them green, then steep them in a hot and strong solution of pearlash.

b. Boil them in a strong decoction of logwood, and afterwards steep them in a solution of blue vitriol.

c. Steep them for a short time in a weak solution of sulphate of indigo, to which a little salt of tartar has been added; or, still better, boil them in a dyer's green indigo vat. *Remarks.* The bones of living animals may be dyed by mixing madder with their food. The bones of young pigeons may thus be tinged of a rose color in 24 hours, and of a deep scarlet in 3 days; but the bones of adult animals take a fortnight to acquire a rose color. The bones nearest the heart become tinged soonest. In the same way extract of logwood will tinge the bones of young pigeons purple. (Mr. Gibson.)

BONE GREASE. *Prep.* By bruising and boiling the refuse bones of the kitchen, and skimming the broth when cold, from $\frac{1}{4}$ (?) to $\frac{1}{8}$ of their

weight of good fat may be obtained, fit for culinary purposes when fresh, but always excellent for making soap and candles. (Proust.)

BONE GLUE. *Syn.* GELATINE. *Prep.* This is made by dissolving out the earth of bones, previously boiled for the grease, washing the remaining jelly with water, then boiling it with a little water, and forming it into cakes for sale. (SEE GLUE.)

BONE MANURE. For this purpose the bones are ground to a coarse powder in a mill, and sowed along with the seed in a drill. It is said that wheat thus treated yields 30 to 50 per cent. more in weight of straw and grain than by the common methods. It is usually applied to light or turnip soils, which it renders more than ordinarily productive. Bone manure is much used in the west of Yorkshire, Holderness, and Lincolnshire. The usual quantity per acre is 70 bushels, when used alone; but when mixed with ashes, as common manure of any sort, 30 bushels per acre is thought quite enough. It is applied at the same periods as other manure, and has been found in this way to remain 7 years in the ground. The rough part of this manure, after being 5 years in the ground, has been gathered off one field and thrown upon another of a different soil, and has proved, even then, good manure.

BONES, (IN COOKERY.) The bones of good meat form most excellent materials for making soups and gravies, as is well known to every good cook. In France, soup is extensively made by dissolving bruised bones in a steam heat of 2 or 3 days' continuance, and also by dissolving out the earthy part by digestion in weak muriatic acid, when a lump of gelatine is obtained, which after being well washed with water will dissolve by boiling, and is equal to isinglass for all the purposes of making soups and jellies. Proust has recommended the following process for making the best of bones, in hospitals, jails, and similar establishments:—Crush the bones small, then boil them for 15 minutes in a kettle of water, cool, and skim the fat off, which varies from $\frac{1}{8}$ to $\frac{1}{4}$ (?) of the weight of the bones employed, and when fresh is fit for all common purposes. The bones are then ground, and boiled in 8 to 10 times their weight of water, of which that already used must form a part, until $\frac{1}{2}$ is wasted, when a very nutritious jelly is obtained. A copper vessel should not be used, as the jelly acts upon this metal. An iron Papin's digester is the most suitable. The bones of boiled meat are nearly as productive as those of fresh meat, but roasted meat bones scarcely afford any jelly. (Dr. Young.) As boning meat before cooking is now a very general practice, a quantity of fresh bones may always be had.

BONE SHAVINGS. *Syn.* BONE DUST. BONE TURNINGS. These yield a beautiful jelly by boiling with water, nearly equal to that produced from hartshorn shavings, for which they are very frequently sold.

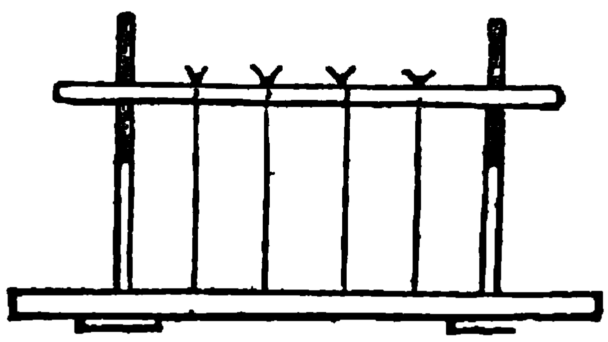
BOOKBINDING. The process of binding books may be divided into several distinct operations, which, in large establishments, are usually performed by different persons, such a method being found to produce greater expedition and better work, than when the whole is done by one person.

The sheets received from the hands of the printer are—

1. *Folded*, which is done correctly by observing the marks or catchwords at the bottom of the pages. As the sheets are folded they are laid upon each other in proper order, and are ready to undergo—

2. *The operation of beating.* This is performed by laying them upon a large stone, and striking them with a heavy smoothed-faced hammer, or by passing them through a rolling press. The former method is usually adopted in the small way, and the latter on the large scale.

3. *The sheets are next fastened to bands*, which is done by taking the folded sheets up one by one, and sewing them to pieces of cord, stretched in a little frame screwed or fastened to the counter or table, called the sewing-press. (See eng.) The



number of bands used, is generally 6 for a folio, 5 for a quarto, and so on proportionally, less than 4 seldom being employed even for small sizes. The ends of the cords being cut off to within about 2 inches of the back, the sheets are ready for—

4. *Glueing.* The back being knocked into shape with a hammer, and the sheets placed in the cutting press, which is then slightly screwed up, melted glue is thinly and evenly applied. After a short time the book is removed from the press, and the back properly adjusted with a hammer, when it is again put into the cutting press, where it is screwed up very tight, and is then ready for—

5. *Cutting.* The instrument employed for this purpose is of a peculiar shape, and called a plough or plough-knife.

6. *Affixing the boards. The bands* are now scraped out fine at the ends, and the pasteboard to form the covers is fastened thereto, and is then properly adjusted, and shaped with a large pair of shears. The edges now undergo the operation of—

7. *Sprinkling*, or other adornment. The first is performed by a stiff brush of hog's bristles, dipped in the color; the brush being held in the one hand, and the hairs moved with the other.

8. *The external covering of leather, fancy cloth, or paper*, is now applied, having been previously well soaked in paste, to make it properly adhere. One or more of the blank leaves of the book are next pasted against the inside of the cover, to screen the ends that are turned over, when the book is finished; or for choice work, is handed to a "*finisher*" for—

9. *Lettering, gilding, &c.* Gold-leaf is applied by means of white of egg, the pattern being given by pressure with heated brass tools, having the design or letters on their surface. The whole is then glazed over and polished.

Remarks. The succession of some of the above operations sometimes varies with the workmen and

the nature of the binding. The above must therefore only be regarded as a short and general outline of the process. If the reader will accompany the perusal by an examination of a bound book, the whole will be rendered quite familiar.

The following varieties of binding may be noticed:

a. Boards. A book, loosely done up without cutting the edges, and covered with paper or cloth, is said to be in boards.

b. Cloth-binding. This style of binding is that in which the majority of works are now issued. It admits of great neatness and even beauty, and is very durable and cheap. *Proc.* The prepared cloth, cut by a pattern to the size suited to the volume, is passed rapidly through a rolling press, between engraved cylinders of hardened steel, which print the pattern in relief. Paste is now applied to the cloth, when it is placed over the volume, previously prepared to receive it. Books in cloth-binding are not commonly cut at the edges, unless highly finished.

c. Dutch binding. This species of binding is distinguished by the backs being of vellum.

d. French binding. This consists in pasting a piece of parchment over the back of the book, between each band, and pasting the ends upon the inside of each cover.

e. Half-binding. Books forwarded in boards, and finished with leather backs and corners, are called "*half-bound.*"

f. Hancock's patent binding. In this method the sheets are folded in double leaves, and being properly placed together and adjusted, the book is subjected to the action of a press, and a strong solution of Indian rubber is smeared over the back with the finger. The operation is repeated, as often as necessary, when fillets of cloth are cemented on with the varnish, and the book is ready to have the boards attached. Thus several of the common operations of binding are dispensed with. I willingly bear testimony to the strength and durability of this method, and the great convenience it affords in allowing the books to open perfectly flat upon a table, or to be distorted in any possible manner, without injury to their backs. It is the best way of binding books for travellers. I once had a large trunk of books, among which was one bound on Hancock's plan. All the rest were nearly torn to pieces by a few months' journey, but this one was uninjured.

g. Law binding. A strong method applied to law books.

h. Leather binding. *Proc.* Immerse the leather in water; after which wring it, and stretch it on a board; place the book with the boards extended thereon, and cut out the cover, allowing about half an inch larger than the book, to turn over the inside of the pasteboards. Pare the edges of the cover very thin all round on a marble slab, and paste it well; glue the back of the book, and spread the cover on the board.

Let the pasteboards be properly squared and even; put the book on the cover, which draw on very tight. Rub the cover smooth with a folding-stick, and turn it over on the inside of the pasteboards on the fore edge. The corners on the inside must be cut and neatly pressed down; tie a piece of thread round the book, between the boards and head-bands, draw up the leather on the back, if necessary, to cover the top of the head-bands; rub the back very smooth with a flat folding-stick, and place it at a distance from the fire to dry.

Rough calf must be damped on the grain side with a sponge and water before pasting and covering.

Russia leather must be well soaked in water fo an hour, taken out, well beaten, and rubbed; afte which the paste must be well worked into the flesh side before covering.

Morocco must be grained by rubbing it on a board, with the grain side inside, and after being pasted, left to soak for a quarter of an hour, and the cover then drawn on with a piece of woollen cloth to preserve the grain.

Roan may be either soaked in water or left to soak when pasted.

i. Italian binding. This is a common variety of binding employed in Italy, (hence its name,) in which the books are covered with a kind of thick coarse paper. In Italy it is called "*alla rustica.*"

k. Marble binding. Named from the design of the exterior.

l. Palmer's patent binding. This consists in applying small brass bars, linked together, to the back of the book, in such a manner that they make the different sections of the book, when open, parallel with each other, and thus admit of writing, without inconvenience, on the ruled lines near the back.

m. School binding. The following is a strong method for school books:—When the books have been cut, colored, and backed, cut off the part of the bands intended to be laced to the pasteboards, and glue on the back a piece of strong smooth linen cloth, which must reach within half an inch of the head and foot, turning on the sides about an inch; paste the boards on each side of the cloth, fixing them close in at the groove, and give the books a firm pressing in the standing-press till dry. Square the boards, glue the backs, and cover and finish in the usual manner.

This method will secure and give strength to the joints, so as effectually to prevent the leather from breaking, and require no more time than lacing in the bands. The edges may now be colored, sprinkled, or marbled, as required.

n. William's patent binding. This consists in placing a back, of a curved form, turned a little at the edges, and made of iron, copper, brass, wood, ivory, or any other material of sufficient firmness. This back is adjusted to the book before it is bound, in such a manner that it may just cover, but not press upon the edges, and is fastened on by enclosing it in vellum or ferret wrappers, which are pasted down upon the boards or drawn through them. The effect is, to make the book open evenly and freely, and to prevent it from spreading on either side.

BOOTS, TO CLEAN. To do this in the best style always use "boot-trees," employ but little blacking, and brush it off while damp. The dirt should, of course, be carefully brushed off before applying the blacking.

BOOTS AND SHOES, WATERPROOF COMPOSITION FOR. *Prep.* Boiled oil 1 pint; oil of turpentine, black rosin, and bees' wax, of each 3 oz. *Proc.* Melt the wax and rosin, then stir in the oil, remove the pot from the fire, and when it has cooled a little, add the turpentine.

II. Take 3 oz. of spermaceti, and melt it in a pipkin, or other earthen vessel, over a slow fire; add thereto 6 drachms of Indian rubber, cut into slices, and these will presently dissolve. Then add *seriatim* of tallow 8 oz.; hog's lard 2 oz.; amber varnish 4 oz. Mix, and it will be fit for use immediately. *App.* The boots or other material to be treated, are to receive two or three coats, with a common bladking brush, and a fine polish is the result.

BOOT-TOP LIQUID. *Prep.* I. Oxalic acid and white vitriol of each 1 oz.; water 1½ pints. *Proc.* Dissolve and apply with a sponge to the leather previously washed with water, then wash the composition off with water, and dry. This liquid is poisonous.

II. Mix in a vial, 1 drachm of oxymuriate of potass, with 2 oz. of distilled water; and when the salt is dissolved, add 2 oz. of muriatic acid. Then shake well together, mix in another vial 3 oz. of rectified spirit of wine with ½ an oz. of the essential oil of lemon, unite the contents of the two vials, and keep the liquid, thus prepared, closely corked for use. This liquid should be applied with a clean sponge, and dried in a gentle heat; after which, the boot-tops may be polished with a proper brush, so as to appear like new leather.

III. Sour milk 1 quart; gum arabic 1 oz.; juice of 2 lemons; white of 2 eggs; oil vitriol 2 oz. Mix.

IV. Sour milk 1 quart; butter of antimony, cream of tartar, tartaric acid, and burnt alum, of each 2 oz. Mix.

BORACIC ACID. *Syn.* SEDATIVE SALT. SED. SALT OF VITRIOL. SED. SALT OF HOMBERG. *Prep.* Dissolve borax in 4 times its weight of boiling water, then add sulphuric acid to the solution until it acquires a distinct acid reaction, (about ½ the weight of the borax.) As the solution cools, crystals of boracic acid will be deposited. These crystals must be then placed on a filter, and washed with a little cold water. They may be still further purified by solution in boiling water and recrystallization.

Remarks. Even after this treatment, the crystals are apt to retain a little sulphuric acid or sulphate of soda, which can only be got rid of by heating them in a platinum crucible, before redissolving them and crystallizing the second time, as above described. When wanted perfectly pure for chemical analyses, this plan must be always adopted.

The boracic acid of commerce is extracted from the acid lagoons of Tuscany.

Prep. As thus obtained, this acid is soluble in 25 times its weight of cold, and 3 times its weight of boiling water. Very soluble in alcohol, which then burns with a bright green flame, offering a sure test of the presence of boracic acid. Odorless, and tastes bitter. Reddens litmus, but browns turmeric paper. It was once administered internally in large doses, (by Cullen,) but is now scarcely ever employed as a medicine.

BORATE. A compound, formed of the preceding acid and one of the bases.

Prop. The boracic acid has but a feeble affinity for the bases; most of the borates being decomposed by the stronger acids, the former being liberated in a free state. *Prep.* Many of them may be formed by digestion of the hydrate of the base in a solution of the acid, with the assistance of heat, or by double decomposition.

Tests. I. By digestion in slight excess of oil of vitriol, evaporating to dryness, powdering, and dissolving in alcohol, the latter will acquire the property of burning with a green flame. II. If to a strong and a hot solution of a borate, sulphuric acid be added in excess, crystals of boracic acid will form as the liquor cools.

BORATE OF MERCURY. *Prep.* I. Neutral borate of soda 265 grs.; calomel 222 grs.; grind together in a mortar, with a little water, then fill the mortar up with hot water; collect the red precipitate; wash and dry.

II. Add a solution of borax to a solution of quicksilver in nitric acid. Collect the precipitate as before. (White.)

BORATE OF SODA. I. (*Neutral borate.*) *Prep.* Saturate boracic acid in solution with carbonate of soda, at a boiling heat. (Berzelius.)

II. (*Biborate.*) This salt, often erroneously called borate and subborate, is the borax of commerce, and is a natural production. (See BORAX.)

BORAX. *Syn.* BIBORATE OF SODA. BORATE OF SODA. SUBBORATE OF SODA. REFINED BORAX. Crude borax is a natural production, and after being refined, forms a large portion of the borax of commerce. In its rough state it is called *crude borax, tincal, tincar,* &c. It is found crystallized on the edges and shallows of a brackish lake in Thibet, during the winter. It is also prepared by saturating the native boracic acid of Tuscany with soda. The market being literally overloaded with the former article, its price has fallen so low as to allow of its employment for this purpose with great advantage. A valuable paper on this subject, by M. Payen, appeared in the "Ann. de Chimie et de Phys." for July, 1841; and a translation of the same in "The Chemist," vol. ii. 368, to which the reader is referred for a complete account of this process.

The best Tuscany boracic acid contains only 50 per cent. of real boracic acid, and yields no more than 140 to 150 per cent. of good borax.

Prop., Use, &c. It is extensively employed as a flux for metals, for soldering, and in medicine. Internally it is diuretic, sedative, emmenagogue, and cooling, in doses of 15 to 40 grains; externally as a gargle for sore throat, and in powder as a detergent in aphthæ, and ulcerations of the mouth. Dissolved in rose-water, it is used as a cosmetic, and mixed with 8 times its weight of lard, forms a useful piles ointment.

Tests. These are the same as for the borates, which see. It reddens turmeric paper, and, before the blowpipe, fuses into glass, which may be tinged red by terchloride of gold, and blue by cobalt.

Pur. The purity and strength of borax are best ascertained by determining the quantity of sulphuric acid required to neutralize a given weight, as indicated by litmus paper. Common salt and alum are frequently mixed with borax to lower the value. The former may be detected by dissolving the borax in hot water, when a solution of lunar caustic will give a curdy white precipitate, soluble in ammonia; and the latter by water of ammonia, which will give a bulky white precipitate. The

former must be distinguished from the white pulverulent precipitate of borate of silver, which will be thrown down from pure borax.

BORAX, GLASS OF. *Prep.* Dry borax with a gentle heat, breaking down the froth as it rises, then melt it by increasing the heat until it runs into a glass. *Use.* In soldering, and as a blowpipe flux.

BORO-FLUORIDE OF HYDROGEN.—*Prep.* Pass fluoboric acid gas through water, and afterwards carefully concentrate the solution; cool and separate the crystalline powder from the solution, which is the boro-fluoride of hydrogen. *Prop., &c.* With most of the protoxides it interchanges bases, and metallic boro-fluorides result.

BORO-FLUORIDE OF BARIUM. *Prep.* Add carbonate of baryta to boro-fluoride of hydrogen, until it ceases to be dissolved; evaporate to the consistence of a sirup, when crystals will form. *Remarks.* The boro-fluoride of calcium, magnesium, and lead, may be formed in a similar way.

BORO-FLUORIDE OF POTASSIUM.—*Prep.* Drop boro-fluoride of hydrogen into a solution of carbonate of potassa, collect the white powder that falls, and wash it with cold water.

BORO-FLUORIDE OF SODIUM. *Prep.* Dissolve fluoride of sodium in boro-fluoride of hydrogen, and crystallize. *Remarks.* Boro-fluoride of lithium may also be formed in a similar way.

BORON. The base of boracic acid, discovered by Sir H. Davy, in 1807, by means of the galvanic battery of the Royal Institute.

Prep. Potassium, and perfectly dry boracic acid, or still better, boro-fluate of potassa, intimately mixed together, are to be placed in an adopter, or glass tube, and submitted to a low red heat. When cool, remove the loose cork that fastened its mouth, and pour in successive portions of hot water, until the whole matter is detached and dissolved. Collect the liquid and allow it to settle, then wash the precipitate, first with a solution of sal ammoniac, and finally, with alcohol; next dry the boron in a capsule, and put it into a well-stopped vial.

Prop., &c. A solid, tasteless, and inodorous powder, of grayish-brown color. With sulphur it unites at high temperatures, forming sulphurets; and when placed in chlorine gas it spontaneously inflames, and a gaseous chloride is produced. This gas may also be made by exposing calcined borax and charcoal at a red heat to the action of dry chlorine.

BOTTLE, RED. *Syn.* TAYLOR'S RED BOTTLE. WHITWORTH DOCTOR'S RED BOTTLE. *Prep.* British brandy 1 quart; powdered cochineal ½ oz.; oil of origanum 10 drops. Digest for 24 hours and filter.

BOUGIE. *Syn.* CANDELA. CANDELA CEREA. CANDELULA. VIRGA CEREA. CEREA. CEREOLA. CEREUS. CEREOLUS. A long slender instrument, introduced into the urethra, œsophagus, or rectum, to overcome strictures of those canals. The word bougie is the French for a wax candle.

Prep. I. Add 3 parts of boiled linseed oil to 1 part of melted amber, and when mixed add 1 part of oil of turpentine; spread the mixture at 3 successive intervals upon loose spun silk cord or web, dry in a heat of 150°, and repeat the process until the instrument has acquired the proper size, then polish, first with pumice-stone, and afterwards with tripoli and oil.

Remarks. The above is the original receipt of the French professor Pickel, and is still generally used, slightly modified, on the continent.

II. Add to the oil and amber melted together, as last, caoutchouc in the proportion of $\frac{1}{20}$ of the weight of the oil employed; when dissolved, remove the vessel from the fire and proceed as before.

Remarks. This is the plan usually adopted at Paris, and for the best elastic bougies this process usually occupies from 6 to 8 weeks. When the bougie is wanted to be hollow, a piece of polished metallic wire is introduced into the axis of the silk, or tinfoil is rolled round the wire and the composition applied as before. When dry and hard the wire is withdrawn.

III. (*Caoutchouc, or elastic gum bougies.*) *a. In France* these are made by applying a solution of Indian rubber in ether, to the silk or foil prepared as above.

b. In England, where ether is expensive, naphtha is employed, or slips of Indian rubber previously boiled in water, or that have had their edges softened with ether, are wound round the wire or foil, and kept in their place by a piece of tape applied over them, as in making elastic tubes. They are afterwards carefully smoothed off.

IV. A common kind of bougie is made by dipping pieces of catgut or soft linen into lead plaster, melted, and rolling it while yet warm upon a slab. *Very inferior.*

V. (*White.*) *Prep.* Yellow wax 1 lb.; spermaceti 1 oz.; finely-powdered sugar of lead ¾ oz.; melt and spread upon slips of old linen, then roll them up while warm with the spread side outwards.

VI. (*Bell's.*) Lead plaster 1 lb.; yellow wax 8 oz.; olive oil 2 oz.; *as last. Very inferior.*

BOUILLI. (French for boiled meat.) This name has been applied by cooks to several dishes of boiled meat, as a refinement on the plain English. Thus "beef bouilli, beef in bouilli, &c.," means, stewed or boiled beef, &c. As, however, the name is à la français, so must be the accompaniments, which generally consist of herbs and vegetable seasoning in greater quantity and variety than is usually deemed essential to a plain-spoken piece of boiled or stewed meat!

BOULES DE NANCY. Equal parts of iron filings and red tartar, made up into balls with spirit. *Use.* As a tonic dissolved in hot water.

BOUQUET DE LA REINE. *Prep.* I. Essence of bergamotte 1 drachm; English oil of lavender 23 drops; oil of cloves and aromatic vinegar, of each 8 drops; essence of musk 10 drops; alcohol ½ oz. Mix.

II. Oils of bergamotte and lavender 30 drops each; neroli 15 drops; oils of verbena and cloves, of each 5 drops. Essences of musk, ambergris, and jasmin, of each ½ drachm; rectified spirit of wine (strongest) 1 oz. Mix.

BOX WOOD MAHOGANY. *Prep.* Warm the wood by the fire, then wash it over with aquafortis, let it stand 24 hours to dry, and polish it with linseed oil reddened with alkanet root, or give it a coat of varnish, made by dissolving aloes and annotto in spirit of wine.

BOYLE'S FUMING LIQUOR. Hydrosulphuret of ammonia is usually employed and sold for this article, but the liquor prepared by Boyle's process contains an excess of sulphur. (Gay Lussac.) The properties of both are however the same.

Prep. Mix 4 parts of fresh slaked lime; 2 of sal ammoniac, and 1 of sulphur, then submit the mixture to distillation.

BRA GRAS. Tar, black rosin, and the dregs of strained rosin, melted together.

BRAIN CAKES. *Prep.* Clean, wash, blanch, and soak the brains, then beat them up with a little white pepper and salt, a sage-leaf or two, scalded and finely chopped, and the yelk of an egg; make them into small cakes or fritters, and fry them.

BRAN. The husk of wheat which immediately covers the grain, and which is left in the bolting machine. *Use.* It is largely employed by the calico printers, when diffused through hot water, to remove the coloring matter from those parts of their goods which are not mordanted. A handful mixed with a pail of warm water, forms an excellent emollient foot-bath. Infused in water, (*bran tea,*) and sweetened, it forms a popular demulcent, much used in coughs and hoarseness, and, taken in quantity, proves gently laxative. It also forms an excellent manure, and, from containing the ammoniaco-magnesian phosphate, is especially adapted for potatoes. It is frequently mixed with flour and made into bread, by the poorer orders.

BRANDY. *Syn.* Eau de Vie. Aqua Vitæ. Spiritus Gallicus. Brandy-wine. The spirituous liquor obtained by the distillation of wine. When first distilled it is colorless, and only acquires a yellowish tint from the wood of the casks, in which state it is known and sold as pale or white brandy. The deep color that it usually possesses, is imparted to it by adding a little spirit coloring, (burnt sugar or caramel,) and occasionally a little red sanders wood as well, and is intended to imitate the appearance acquired by brandy from great age, when kept in wood. The natural color, however, which the spirit receives from the cask, no matter how long it may have been in it, never exceeds an amber tint, about the common color of pale Jamaica rum; but the public taste has been gradually vitiated in this respect, until only a spirit of a lively and full "*brandy color*" (unless for a pale brandy) will sell.

The brandies most esteemed in England are imported from France, and are those of Cognac and Armagnac, the preference being generally given to the former. The brandies of Rochelle and Bordeaux may be reckoned next in quality, while those obtained from Portugal, Spain, and Italy are very inferior.

The constituents of brandy are alcohol and water, and small quantities of volatile oil, acetic acid, acetic ether, œnanthic ether, coloring matter, and tannin. It is from the presence of the last six of these substances that the spirit derives its distinguishing smell and flavor. The quantity of alcohol present in brandy varies from 48 to 55 per cent. When first imported, it is generally 1 or 2 overproof, but by age its strength is lessened, and by the time it is usually taken from the bond store for sale, seldom exceeds 3 or 4 underproof. From considerable personal acquaintance with the cognac trade, I feel confidence in asserting, that brandies of the best quality seldom exceed proof, and are generally below it, and that it is a common practice in France to add spirit of wine and coloring to raise the strength to any given point desired by the English purchaser, and to charge the same in the invoice; or where the purchaser is not *well acquainted with the subject,* and desires a strong spirit at a low rate; to sell him brandy so mixed as genuine. The very finest brandies average from 5 to 10 u. p., and never exceed about 2 u. p.; they then contain more than ½ their weight of water, and from their boiling point being higher, they come over more highly charged with essential oil, and other volatile and fragrant principles of the grape, and thus possess in a greater degree that peculiar aroma and flavor for which they are so much esteemed. French brandy or wine, distilled at a low temperature in a water bath, yields a very pure and scarcely flavored spirit.

The quality of the brandy imported from France varies considerably from that which is drunk on the continent, principally from its being *prepared,* or, as it is technically termed, "*made up,*" for the London market, which means lowering it by the addition of spirit, coloring, &c. above described. The common strength at which foreign brandy is sold in England is about 11 or 12 u. p., and below 17 u. p. it becomes seizable by the excise. The strength at which it is sold and permitted in trade, is generally 10 u. p., to which it is reduced by adding water, and never less than 12 u. p., unless it be specially agreed upon. In large quantities and from bond, of course the strength depends much upon the age and quality of the spirit. A fine old brandy being, perhaps, 8 or 10 *u. p.*, while one of the last year's vintage of a commoner quality may be as strong as 2 or 1 *u. p.* But these distinctions are familiar to every experienced brandy dealer.

In France there are several varieties of this spirit distilled, which are known by names descriptive both of their quality and source. The "*eau de vie supérieure,*" or *cognac brandy,* is generally obtained from pale white wines, by careful distillation, and is remarkable for its superior flavor. When kept in glass or stone bottles, it is called white cognac brandy, and the same term is also generally applied when it has been kept in casks, but has not been artificially colored; in the latter case, however, it generally acquires a pale amber tint.

The "*eau de vie ordinaire,*" or *common brandy,* is distilled from high-colored white or red wines, and has generally a sp. gr. of 0·948, and varies from 22 to 27 u. p.

The "*eau de vie de marc*" is obtained from the lees of vinegar and other wines, the marc or cake of grapes from which the juice has been pressed, and the commonest red wines, fermented and distilled together by a quick fire, to drive over as much essential oil and flavoring as possible.

The "*eau de vie seconde*" is the weak spirit that passes over after the stronger spirit has been drawn off, and the receiver changed. *It is used* for common drinking, or mixed with other brandy.

The "*eau de vie à preuve d'Hollande*" is brandy about 19° Baume, or sp. gr. ·9420, the common strength at which it is retailed in France, and will stand the "*proof*" or "*bead*"

The "*eau de vie à preuve d'huile*" is the strongest brandy usually drunk; it is about 23° Baume, or sp. gr. ·918; pure olive oil will just sink in it; hence the above term.

The "*eau de vie fort*" is usually prepared by the redistillation of common brandy, keeping the first portion separate. It answers to our spirit of wine. It is made of 12 different strengths, distinguished by names, exhibiting the quantity of water required to reduce the sample to the "*preuve d'Hollande*." The weakest is called cinq-six, or $\frac{5}{6}$, and the strongest trois-neuf, or $\frac{3}{9}$, the difference between the numerator and the denominator being the quantity of water the 3 parts of the former will take to reduce it to the "*preuve*," when it would make 9 parts. Its sp. gr. is about ·839.

The *esprit de vin* is brandy or spirit rectified to 0·890 and upwards.

The general method of distilling brandy in France differs in no important particular from that practised in England, for grain or molasses spirit. Neither are the French workmen more skilful nor more cleanly in their operations than the English. It is the materials alone that, in this case, conduce to the superiority of the product. The quality of the brandy varies with that of the wine from which it has been distilled. Every soil, every climate, every kind of grape, produces a wine possessing some peculiarity confined to itself, and this wine on distillation produces a spirit possessing like distinctions. A large quantity of brandy is prepared in France soon after the vintage, as the juice of the poorer grapes that is unfit for wine is fermented and at once distilled. It is a general rule, in France, to distil only such wines as are unsaleable, as the profits on the wine, sold as such, are much greater than when it is converted into brandy.

The Strength of Brandy may be ascertained in the same way as alcohol, for which purpose Sike's hydrometer is used in England. In France, from the value of spirit being less, it is frequently tested by simpler methods, though great accuracy obtains, in this particular, where necessary.

Pur. Very little perfectly pure French brandy is obtained by the small consumer in England, as it is not only generally lowered a little by the wholesale dealer, but undergoes a like process at the hands of the retailer. The safest method is either to procure it direct from the bond store, without its even entering a private cellar, or to buy of some known respectable party, and to pay a price that will offer no inducement to dishonesty. If this be not done, by all means buy British brandy, which is now made of excellent quality by many of the leading houses, as *Betts, Bretts, Booth*, and *Grimble*. From the two former a single sealed bottle may be procured at the same price as by the gallon.

The importation of foreign brandy for home consumption amounts to about 1,400,000 gallons a year.

BRANDY, (REDUCED.) I. To 20 gallons of Cognac brandy add 5 gallons of the best British brandy.

II. To 72 gallons of full-flavored French brandy, add 10 gallons of spirit of wine, (58 *o. p.*,) 8 gallons of water, and 1 pint of good coloring. Rummage well up and let it stand until the next day.

Remarks. The above reduction is generally adopted in trade, and is known by the name of "*improving*." But such is the poverty of the palate of the English brandy drinker, that the adulteration is often not suspected, even when it is carried to double the extent of the above, which is generally exceeded in the hands of the retailer. So long, however, as the foreign spirit constitutes about half of the mixture, and was at first of decent quality and age, the infatuated Englishman smacks his lips, and cunningly holding up his glass between the light and his eye, exclaims, "*Ah! this is a drop of the real.*"

BRANDY, (BRITISH.) *Syn.* British Cognac. Imitation Cognac, &c. From the heavy duty levied on French brandy imported into England for home consumption, it has become a desideratum with the distiller (rectifier) to produce an English spirit of a similar description. For some time the attempt proved quite unsuccessful, but of late years much capital and talent have been embarked in the pursuit, and the result has proved very satisfactory. An article of British manufacture may now be purchased, at a very reasonable rate, of really respectable quality, and possessing much of the flavor and aroma of foreign brandy, while, as a beverage, it is equally wholesome. Much of the British brandy, however, that is commonly met with, is of such a wretched quality as to be quite undeserving of the name, which is evidence of the fact, that much skill and experience is required to ensure success in its manufacture. For a long time this liquor was distilled from spoilt wine and dregs of wine, both British and foreign, mixed with beer bottoms and similar articles; and when, instead of these, corn, malt, and molasses spirit were employed, it was considered as an unpardonable and wicked misuse of those articles. Modern experience has proved, however, that perfectly pure and tasteless malt spirit is the best article to form into an imitation brandy.

The following formulæ, by skilful management, will produce very good brandy, but it must be recollected that much depends on the quality of the materials employed, as well as on the operator. As the strength and quality of the ingredients, and the methods of manipulation vary, so will the result; much must therefore be left to the judgment and discretion of the artist. It offers a profitable pursuit to the ingenious and industrious chemist and rectifier.

Prep. I. Take 12 gallons of the finest flavorless malt spirit at proof, (or if of a different strength a proportionate quantity;) add thereto 5 gallons of water, $\frac{3}{4}$ lb. of the best crude red tartar or winestone, previously dissolved in 1 gallon of boiling water; $\frac{1}{4}$ pint of acetic ether; 2 quarts of good French wine vinegar; 7 lbs. of bruised French plums, and 1 or 2 gallons of wine bottoms or flavor stuff from Cognac, mix them in a fresh-emptied sherry cask, and let them stand together for 14 days, frequently rummaging up the liquor with a stick; next draw over 15 gallons of the mixture from a still furnished with an agitator. Put the rectified spirit into a clean, fresh-emptied Cognac brandy cask, and add thereto $\frac{3}{4}$ pint of tincture of catechu, 1 lb. of fresh and clean oak shavings, and about a pint of good spirit coloring. Bung close, and agitate occasionally for a few days. *Remarks.* Age improves the above article, and renders it

(provided the process be well managed) of a very superior quality. The above receipt yields 15 gallons of brandy 17 *u. p.* The following forms may also be recommended:—

II. Perfectly pure spirit, pf. 99 gallons; red tartar, dissolved, 7 lbs.; acetic ether 3 lbs.; wine vinegar 3 gallons; bruised raisins, or French plums, 7 lbs.; bitter almonds, bruised, 1 oz.; water sufficient. Dissolve the tartar in the water, then add the other ingredients, macerate as before, and draw over 120 gallons; lastly, add a few lbs. of oak shavings, 1 lb. of powdered catechu made into a paste with water and burnt-sugar coloring as before. *Remarks.* This yields 120 gallons of spirit fully 17 *u. p.*

III. Clean spirit 17 *u. p.*, 100 gallons; nitric ether 2 quarts; cassia buds, ground, 4 oz.; bitter almond meal 2 oz.; orris root, sliced, 6 oz.; powdered cloves 1 oz.; capsicum 1½ oz.; good vinegar 2 gallons; brandy coloring 1 quart; powdered catechu 1 lb.; full-flavored Jamaica rum 2 gallons. Mix well in an empty Cognac cask, and let them macerate for a fortnight, occasionally stirring. *Remarks.* The proportion of the ingredients may be varied by the skilful brewer, as much depends on their respective strengths.

IV. Good plain malt spirit, 17 *u. p.*, 100 gallons; finely-powdered catechu 12 oz.; tincture of vanilla 4 oz.; burnt-sugar coloring 1 quart; good rum 3 gallons, or more; acetic or nitric ether 2 quarts. Mix well.

V. Clean spirit, 17 *u. p.*, 89 gallons; high-flavored cognac 10 gallons; oil of cassia 1½ drachms; oil of bitter almonds, essential, ½ a drachm; powdered catechu 10 oz.; cream of tartar, dissolved, 16 oz.; Beaufoy's concentrated acetic acid 3 lbs.; sugar coloring 1 quart, or more; good rum 1 gallon. Put the whole into a fresh emptied brandy piece, and let them remain a week together, with occasional agitation, then let them stand to settle. If this mixture be distilled, the French brandy, rum, coloring, and catechu, should not be added till afterwards.

VI. To colored plain spirit at 17 *u. p.*, add a little tincture of catechu, and a sufficient quantity of essential oil, distilled from wine lees, to give it a proper flavor. This oil is obtained by distillation from the wine lees, either dried and made up into cakes, or in their wet state mixed with about 7 times their weight of water. It should be dissolved in alcohol, and kept in this state, as it is apt to lose its flavor. *Remarks.* When this process is well managed a very capital article results, but it requires considerable address to conduct it well. The spirit produced by this plan is better for distillation. The brandy from any part of the world may thus be imitated, by distilling the oil from the lees of the wines produced in the particular district. This is the only method of producing an exact imitation. A pound each of finely-powdered charcoal and ground rice has been recommended to be digested in a gallon of spirit for a fortnight. Where black tea is cheap, as in America, it is very commonly employed to impart the roughness and flavor of brandy to colored spirits.

BRANDY, CHERRY. *Prep.* I. To every gallon of brandy put an equal measure of cherries, bruised between the fingers; steep for 3 days, then express the liquor; add 2 lbs. of lump sugar, and strain for use.

II. To the above add 1 quart of raspberries, and ½ a pint of orange-flower water. *** Quality very fine.

III. Treacle 1 cwt.; spirit (45 u.p.) 41 gallons; bruised bitter almonds (more or less, to taste) 5 oz.; cloves 1 oz.; cassia 2 oz. Put the ingredients into a large cask, well mix and let them lie a month, occasionally stirring.

Remarks. Equal parts of fully ripe Morello and black cherries produce the richest cordial.

BRANDY, CARAWAY. *Prep.* I. Steep 4 oz. of bruised caraway seeds and 2 lbs. of sugar in 1 gallon of British brandy, for a fortnight.

II. Sugar 1 lb.; caraways 1 oz.; 3 bitter almonds; spirits of wine and water, of each 1 quart; (or spirit 22 u.p. ½ a gallon.) Macerate as above.

BRANDY, DANTZIC. This is distilled from rye, ground with the root of calamus aromaticus. It has a mixed flavor of orrice and cinnamon.

BRANDY, LEMON. *Prep.* I. Steep ¼ lb. of fresh lemon peel and ½ a dozen lemons, cut in slices, in 1 gallon of brandy, for a week, then add 1 lb. of lump sugar.

II. Proof spirit 7 gallons; essence of lemon 3 drachms; sugar 5 lbs.; tartaric acid 1 oz., dissolved in water 2 gallons; coloring q. s. Mix, and rummage repeatedly for 14 days. *Remarks.* Sometimes milk is added to the above, in the proportion of 1 quart (boiling hot) to every gallon.

BRANDY, MALT. Malt spirit, flavored with sweet spirits of nitre and terra Japonica, and colored with treacle, or spirit coloring. (See BRIT BRANDY.)

BRANDY, ORANGE. This may be made in a similar way to lemon brandy.

BRANDY, PEACH. *Prep.* I. From peaches, by fermentation and distillation. Much used in the United States, where peaches are very cheap.

II. Bruise the peaches, then steep them in twice their weight of British brandy, or malt spirit; lastly, express the liquor.

III. Bitter almonds (bruised) 2 oz.; proof spirit (light) 10 gallons; water 3 gallons; sugar 5 or 6 lbs.; orange-flower water ½ a pint. Mix, and macerate for 14 days.

*** Color with brandy coloring, if *required* darker.

BRANDY, RASPBERRY. *Prep.* I. Pour as much brandy over raspberries as will just cover them; let it stand for 24 hours, then drain it off, and replace it with a like quantity of fresh spirit; after 24 hours more, drain this off and replace it with water; lastly, drain well, and press the raspberries quite dry. Next add sugar to the mixed liquors, in the proportion of 2 lbs. to every gallon, along with a ¼ of a pint of orange-flower water.

II. Mix equal parts of mashed raspberries and brandy together, let them stand for 24 hours, then press out the liquor. Sweeten as above, and add a little cinnamon and cloves, if agreeable; lastly, strain.

BRASS. An alloy of copper and zinc.

Hist. and Prep. Brass was formerly manufactured by cementing granulated copper, or copper clippings, with calcined calamine and charcoal, in crucibles, exposed to a bright heat. The alloy

was found in lumps at the bottom of the crucible on cooling. These were remelted and cast into ingots. At the present day, brass is generally made by direct union of the metals. This process requires much care, owing to the different degrees of fusibility of copper and zinc. The proper quantity of zinc is first melted, and slips of copper plunged into it, which are rapidly dissolved, as it were, and the addition is continued until an alloy is formed, somewhat difficult of fusion, when the remainder of the copper is added. The brass thus formed is broken into pieces, and remelted under charcoal, and a proper addition of either zinc or copper made, to bring it up to the color and quality desired. It is next cast into plates, or other forms, in moulds of granite. When submitted to the rolling-press for reduction to *thin* plates, it requires to undergo the operation of annealing several times.

Prep. I. (*Fine Brass.*) 2 parts of copper to 1 part of zinc. *Remarks.* This is nearly 1 equivalent each of copper and zinc, if the equivalent of the former metal be taken at 63·2; or 2 equivalents of copper to 1 equivalent of zinc, if it be taken, with Liebig and Berzelius, at 31·6.

II. Copper 4 parts, zinc 1 part. An excellent and very useful brass.

III. (*Gold-colored Brass.*) *Syn.* Red Brass. Dutch Gold. Tombac. Similor. Prince's Metal. Pinchbeck, &c.

a. Copper and zinc, equal parts.

b. Copper 2 parts; zinc 1 or 1½ parts. This is Manheim gold.

c. Copper 3 to 5½ parts; zinc 1 part. Deep colored.

Remarks. The proportion of zinc in this alloy is altered to suit the color and other properties to the purposes for which it is intended, and often varies from ⅓ to ½, or ⅙ of the weight of the alloy. At the celebrated works of Hegermühl, near Potsdam, the proportions are 11 parts of copper to *two* of zinc, which produces a metal which is afterwards rolled into sheets for the purpose of making Dutch leaf-gold.

BRASS, BUTTON. (*Best.*) I. Copper 8 parts; zinc 5 parts, as above.

II. (*Common.*) Copper 50 parts; zinc 40 parts; tin 4 parts; lead 6 parts.

BRASS, FOR SOLDER. *Syn.* Hard Solder. I. 12 parts of brass; 6 parts of zinc, and 1 of tin, melted together.

II. 2 parts of brass, and 1 of zinc.

III. (*Very strong.*) 3 parts of brass, and 1 of zinc.

BRASS, TURNER'S. 98 parts of brass, and 2 of lead. *Remarks.* The addition of lead improves the brass for the uses of the turner, but lessens its malleability.

BRASS, CLEANING OF. Brass and copper are best cleaned with sweet oil and tripoli, powdered bath-brick, rotten-stone, or red brick-dust, rubbed on with flannel and polished with leather. A strong solution of oxalic acid in water gives brass a fine color. Vitriol and spirits of salts make brass and copper very bright, but they very soon tarnish, and consequently require more frequent cleaning. A strong lye of roche-alum and water will also improve brass.

Brass inlaid work may be cleaned as follows:—Mix tripoli and linseed oil, and dip into it a rubber of hat, with which polish the work. If the wood be ebony or rosewood, polish it with a little finely-powdered elder-ashes; or make a paste of rotten-stone, a little starch, sweet-oil, and oxalic acid, mixed with water. The ornaments of a French clock are, however, best cleaned with bread-crumb, carefully rubbed, so as not to spoil the woodwork. Ormolu candlesticks, lamps, and branches, may be cleaned with soap and water. They will bear more cleaning than lacquered articles, which are spoiled by frequent rubbing, or by acids, or strong alkalis.

BRASS COATING. I. Brass plates and rods may be covered with a superficial coating of brass, by exposing them in a heated state to the fumes of melted zinc, at a high temperature. *Use.* For rolling into thin plates, or drawing into wire. The celebrated spurious gold wire of Lyons is thus made.

II. Vessels of copper may be coated with brass, internally, by filling them with water strongly acidulated with muriatic acid, adding some amalgam of zinc and cream of tartar, and then boiling for a short time.

BRASS-COLORED PIGMENT. *Syn.* Brass Bronze. *Prep.* I. (*Red.*) Grind copper filings, or precipitated powder of copper, with a little red ochre.

II. (*Yellow or gold-colored.*) Gold-colored brass, or Dutch leaf reduced to a very fine powder.

Remarks. Both these powders are mixed up with varnish, and used as a paint. No more should be mixed at a time than wanted for immediate use. They are also used by dusting them over any surface, previously covered with varnish to make them adhere. (See Oxide of Copper.)

BRASS-COLORED VARNISH. *Prep.* Dissolve 1 oz. each of pale shell lac and gum sandarach, in ½ a pint of rectified spirit of wine.

Use. To mix up the preceding powders.

BRASS, PASTE FOR CLEANING. *Prep.* I. Soft soap 2 oz., rotten-stone 4 oz.; beat them to a paste.

II. Rotten-stone made into a paste with sweet oil.

III. Rotten-stone 4 oz.; oxalic acid 1 oz.; sweet oil 1½ oz.; turpentine enough to make a paste.

Use. To clean brass. The first and last are best applied with a little water. The second, with a little spirits of turpentine, or sweet oil. Both require friction with soft leather.

BRASS ORNAMENTS, PRESERVATION OF. Brass ornaments, when not gilt or lacquered, may be cleansed, and a fine color given to them by two simple processes. The first is to beat sal ammoniac into a fine powder, then to moisten it with soft water, rubbing it on the ornaments, which must be afterwards rubbed dry with bran and whiting. The second is to wash the brass-work with roche alum boiled to a strong lye, in the proportion of an ounce to a pint; when dry, it must be rubbed with fine tripoli. Either of these processes will give to brass the brilliancy of gold.

BRASS STAIN. I. Cut sheet-brass into small pieces, and expose it to a strong heat for 2 or 3 days, then powder it, and again expose it for several days to a like heat; again powder and sift,

and expose it a third time to heat, testing it occasionally, to see if it be properly burnt. When this is the case, a little of it fused with glass will make the latter swell and froth up.

Uses, &c It imparts to glass a green tint, passing into torquoise.

II. Calcine equal parts of plate-brass and sulphur, stratified together in a crucible, until they become friable; then powder and expose them again, as last.

Use. Imparts a calcedony red or yellow tinge to glass by fusion, according to the mode of using it.

BRAWN, CHOICE. When young, the horny parts feel moderately tender; if the rind be hard, it is old.

BRAWN, MOCK. *Prep.* Take the head and belly piece of a young porker, well saltpetred; split the head and boil it; take out the bones and cut it to pieces; then take four ox-feet boiled tender, and cut them in thin pieces; lay them in the belly piece, with the head cut small; roll it up tight with sheet tin, and boil it four or five hours. When it comes out, set it up on one end, put a trencher on it within the tin, press it down with a large weight, and let it stand all night. The next morning take it out of the tin, and bind it with a fillet, put it into cold salt and water, and it will be fit for use; it will keep a long time, if fresh salt and water are put into it every four days.

BRAZIL WOOD. *Syn.* Sapan Wood. Saint Martha Wood. Fernambuca. This wood is much used in dyeing. A decoction is made by boiling for some hours in hard spring water, and this is generally kept for some time, or until it undergoes a species of fermentation, as it is thus found to yield more permanent and beautiful colors than when employed quite new. *Use.* To dye *red.*

BRAZIL WOOD DYE. I. (*For cotton and linen.*) *a.* First boil the goods in a bath of sumach, next work them through a weak mordant of solution of tin, and then run them through the Brazil bath, lukewarm. This gives a bright red.

b. First alum the goods and rinse them, then give them a mordant of solution of tin, rinse again, and turn them through the dye-bath. This gives a rose color.

Remarks. The shades of this dye may be varied by the strength of the bath, mordant, &c. A little alum added to the Brazil-bath, gives a purple tint. 1 lb. of Brazil wood, ½ oz. of alum, and 2 oz. of tartar will dye 20 to 25 lbs. of cotton.

II. (*For silk.*) The silk, after being well alumed in the same way as wool, but at a lower temperature, is rinsed, and passed through the decoction of Brazil, just lukewarm.

Remarks. By adding a little alkali to the bath, or by passing the silk through a water holding a little alkali in solution, after it is dyed, will produce what is called the false crimson. When wanted of a very deep crimson, a little logwood is added to the Brazil-bath. In this way any shade of color may be produced.

III. (*For wool.*) Boil the wool in water holding in solution 5 parts of alum and 1 of tartar, for 1 hour; then let it lie in the cold liquor for several days, frequently moving it about; lastly, boil it in a decoction of Brazil for ½ an hour.

BRAZILINE. *Syn.* Brezilinе. The coloring principle of Brazil wood, obtained by Chevreul in small orange-colored needles. It is soluble in both water and alcohol; alkalis turn it violet, acids yellow. With alum it dyes red.

BRAZING. The operation of uniting the edges of pieces of copper, brass, iron, &c., by means of hard solder.

Proc. The edges, after being filed quite clean, are covered with a mixture of hard solder and powdered borax, made into a paste with water. The whole is then allowed to dry, and afterwards exposed in a clear fire to a heat sufficient to melt the solder.

Remarks. In some cases a little silver is added to the solder, when it receives the name of "*silver solder.*"

BREAD. *Principles of bread-making, &c.* This most important article of food is made of the flour of different grains, but only those that contain gluten admit of conversion into light spongy bread. Hence it is that wheat flour is best calculated for this purpose. When flour is made into a stiff paste or dough with water, and rolled into cakes and baked, it forms biscuits, or unleavened bread, which was once the only description known. When the dough, previously to baking, is left for some time in a moderately warm place, varying from 80° to 120°, a state of fermentation comes on, formerly called the panary fermentation, but which is, in reality, the sugar of the flour gradually undergoing the process of conversion into alcohol, and resembles in every respect the same change which takes place in the manufacture of wine, beer, &c. During this process, a large quantity of carbonic acid gas is liberated, and the toughness of the dough preventing its escape, the whole mass becomes puffed up and spongy, and a light porous paste is formed, ready for baking into bread. The natural process of fermenting the dough just described, is, however, subject to much uncertainty, and is inconvenient from the time it occupies to complete it, and the tendency the dough has to run into the acetous fermentation, when it acquires a sour and disagreeable taste, and is rendered less nutritious and easy of digestion. This has led to the use of a *ferment*, which at once excites a proper state of fermentation throughout the mass, and speedily renders it light and spongy. *Leaven* or *dough*, already in a state of fermentation, was originally employed for this purpose, and the bread so made was hence called *leavened bread.* But this has been wholly superseded by barm or yeast. Thus it will be seen that all that is essential to make a loaf of bread, is to add a proper quantity of yeast to the dough, and to allow it to remain for a short time in a warm place, until it rises or becomes spongy, when it must be subjected to the operation of baking. If the process be well managed, and the flour be good, bread of superior quality will be produced.

Process of making bread. In preparing his dough, the modern baker takes a part of the water needed for the batch, and having warmed it to a temperature of about 80° or 90°, dissolves his salt therein, and then adds the yeast and a portion of the flour. These he works up into a dough, which he sets aside in a warm place usually provided for

the purpose, and called the "*kneading trough*," where it soon begins to ferment and swell up. This process is called "*setting the sponge*," and according to the proportion the water in it bears to the whole quantity that is to be used, it receives the name of "*whole*," "*half*," or "*quarter sponge*." The evolution of carbonic acid in the process of fermentation, causes the sponge to heave and swell, and when the surface bursts, it subsides, and then swells again and again in a similar manner. This action would go on for some time, if not interfered with; but the baker is careful to stop it before it has communicated a sourness to the mass. After the *first*, or at the *furthest*, after the second or *third* "*dropping of the sponge*," he adds the remaining quantity of flour, water, and salt, necessary to form the batch. These he incorporates by long and laborious kneadings, until the entire mass acquires uniformity, and is sufficiently tough and elastic to bear the pressure of the hand without adhering to it. The dough is now left to itself for a few hours, during which time fermentation goes on, after which the inflated mass is again kneaded, when it is ready to be cut into pieces and weighed. These pieces are then shaped into loaves, and set aside for an hour or two, during which time they swell up to nearly double their former size; they are then placed in the oven and baked. During this operation they continue for a time to increase in size, in consequence of the dilation of the pent-up gas by the heat of the oven, until at length the fermentation is checked, and the dough becomes too solid to admit of further alteration.

Remarks. A number of other processes are used by cooks and confectioners to make the different varieties of fancy bread, cakes, puddings, &c., most of which vary according to the peculiar characteristic it is desired to communicate to them. Thus some kinds of cakes and pastes are made to eat "*short*," as it is called, or are rendered less tenacious, and a species of brittleness imparted to them by the addition of starch and sugar. In pastry a similar effect and peculiar lightness is produced by butter or lard, while in some articles, white of egg, gum-water, isinglass, and other adhesive substances are added to produce an exceedingly light and porous mass.

The different varieties of bread made in England vary chiefly in their quality, according to the flour of which they are formed. *The best white bread* is made from the purest wheat flour; *ordinary wheaten bread*, of flour to which a little of the finest bran has been added; *seconds*, from flour containing a still larger portion of bran; and common household bread, from flour produced by grinding the whole substance of the grain without any separation of the bran. Symnel bread, manchet or roll bread, and French bread are varieties made of the purest flour, from the finest wheat, a little milk being usually added for rolls, and butter and eggs for choicer purposes. Several other minor kinds of bread are also made, varied by the addition of sundry trifles, as sugar, currants, and other palatable ingredients. The Scotch "short bread" is made from a *very thick dough*, to which butter, sugar, orange-peel, and spices, are added. (See GINGERBREAD.)

In France a number of different kinds of bread are made. The "*pain bis*" is the coarsest sort, and is made of a mixture of groats and wheat flour; the "*pain bis blanc*" is made of a mixture of oatmeal and wheat flour; the "*pain blanc*" of flour from which the finest portion has been sifted; the "*pain mollet*," or soft bread, is made of the purest wheat flour, from the finest grain; the "*pain chaland*," made from the same materials as the last, but the paste is pounded; the "*pain chapalé*" is a small variety of bread, similar to the French or roll bread of England; the "*pain cornu*" is a kind of small bread, named from being done up into four-cornered pieces; the "*pain de la reine*" is another variety of small bread, and the "*pain gruau*" is a bread which has been made of late years in Paris, prepared from the small granular particles separated from the best wheat after a slight grinding. The French have also their soup bread and their country white bread, besides several other varieties, not mentioned in the above list.

In the manufacture of white bread from damaged or inferior flour, a large quantity of alum is employed by the bakers, but with the best flour no alum is required. The utmost beauty, sponginess, and sweetness, may be given to bread without the addition of one particle of alum, provided the best materials are employed. As such is not, however, generally the case, it is a common practice with the bakers to introduce 4 or 5 oz. of alum to every sack of flour, or about 1 oz. to each bushel. The method of detecting this adulteration will be presently explained. The proper quantity of salt to be used is 6 or 7 lbs. to the sack, or 1¼ lbs. to the bushel. 1 sack of the best flour, and 6 lbs. of salt, ought to yield about 360 lbs. of *good bread*, and a sack of seconds 345 to 350 lbs. of bread.

Wheaten bread, made of pure materials, is one of the most wholesome articles of food, and has been justly termed the staff of life. When well fermented and baked, it is very easy of digestion. It should never be eaten till it has stood 24 hours after being taken out of the oven, as newer bread is apt to disagree with the stomach, frequently producing flatulence, heartburn, and indigestion.

Adult. This is often carried to a fearful extent: Mr. Accum says, "The bakers' flour is very often made of the worst kinds of damaged foreign wheat, and other cereal grains mixed with them in grinding the wheat into flour. In this capital, no fewer than six distinct kinds of wheaten flour are brought into the market. They are called fine flour, seconds, middlings, fine middlings, coarse middlings, and twenty-penny flour. Common garden beans and peas are also frequently ground up among the London bread flour.

"The smallest quantity of alum that can be employed with effect to produce a white, light, and porous bread, from an inferior kind of flour, I have my own baker's authority to state, is from 3 to 4 oz. to a sack of flour weighing 240 lbs."

"The following account of making a sack of five bushels of flour into bread, is taken from Dr. P. Markham's 'Considerations on the Ingredients used in the Adulteration of Flour and Bread,' (p. 21:) 5 bushels of flour; 8 oz. of alum; 4 lbs. of salt; ½ gallon of yeast, mixed with about 3 gallons of water.

"Another substance employed by fraudulent

bakers is subcarbonate of ammonia. With this salt they realize the important consideration of producing light and porous bread from spoiled, or, what is technically called, *sour flour*. This salt, which becomes wholly converted into a gaseous substance during the operation of baking, causes the dough to swell up into air bubbles, which carry before them the stiff dough, and thus it renders the dough porous; the salt itself is at the same time totally volatilized during the operation of baking. . . Potatoes are likewise largely, and perhaps constantly, used by fraudulent bakers, as a cheap ingredient, to enhance their profit. . . . There are instances of convictions on record, of bakers having used gypsum, chalk, and pipeclay, in the manufacture of bread."

A gentleman, lately writing from the north of England, says that he found in one sample of flour which he recently examined, upwards of 16 per cent. of gypsum, and in another 12 per cent. of the same earth.

Sometime since it was discovered that some of the bakers in France and Belgium added blue vitriol to their dough to make it take more water. It is said that they dissolved 1 oz. of this sulphate in a quart of water, and added a wine-glassful of this solution to the water necessary to make about 50 4 lb. loaves. To the credit of the English baker, no such poisonous materials have ever been found mixed with his bread. *This fraud* may be discovered by boiling a little of the bread in water, to which 5 or 6 drops of nitric acid have been added, and testing the filtered liquor with prussiate of potash, which will give a brown precipitate if copper be present.

Alum may be detected by boiling the bread in water, and adding a little chloride of barium or lime water, or a little water of ammonia, either of which will produce a white precipitate.

Chalk, whiting, burnt bones, plaster of Paris, and similar substances are easily detected by burning a little of the flour or bread in a clean open vessel, when the amount of ashes left will indicate the quantity of adulteration. The quantity of ashes left by genuine flour is very trifling indeed.

Caution. If you purchase bread from the bakers, by all means buy the *best*. When you make it yourself, however, various additions may be made of a wholesome kind, that will render it cheaper. Thus mashed potatoes, ground bran, potato farina, and several other articles may be added at pleasure. Mixing the flour up with a decoction of bran, pumpkins, Iceland moss, and some other similar substances, has been recommended, and it is said that flour so mixed will yield *one quarter* more bread than when water *alone* is used, and that it will keep good for some time.

BREAD, BEE. This is the matter collected by the bees to form the bottom of the hive; it resembles a mixture of rosin and wax; its fumes are thought to be anti-asthmatic.

BREAD, BRAN. *Prep.* I. Mix with ½ a peck of flour, containing the whole of the bran, a ¼ of a pint of small-beer yeast, and a quart of lukewarm water; stir it well with a wooden spoon until it becomes a thick batter, then put a napkin over the dough, and set it about three feet from the fire, until it rises well. Add, if requisite, a little more warm water, strew over it a tablespoonful of salt, and make the whole into a stiff paste. Put it to the fire, and when it rises, again knead it into the dough. If baked in tins, the loaves will be improved.

II. To every pound of flour add ¼ lb. of bran, and proceed as above.

BREAD, EXTEMPORANEOUS. *Prep.* I. (*Ammoniacal Bread.*) Dissolve 1 oz. of sesquicarbonate of ammonia in water, sufficient to make 7 lbs. of flour into a dough, which must be formed into loaves and baked immediately.

II. Divide the flour (8 lbs.) into two portions; mix up the first with water, holding in solution 2 oz. of bicarbonate of soda, and the second with the other portion, to which 1 oz. of muriatic acid has been added. When each mass of dough has been separately well kneaded to a proper consistence, mix them together (perfectly) as quickly as possible; form the mass into loaves, and bake immediately.

Remarks. This bread is considered very wholesome. It contains no yeast.

BREAD, FRENCH. *Prep.* I. Put 1 pint of milk into 3 quarts of water. In winter let it be scalding hot, but in summer, little more than milk-warm: put in salt sufficient. Take 1½ pints of good ale yeast, free from bitterness, and lay it in 1 gallon of water the night before. Pour off the yeast into the milk and water, and then break in rather more than ¼ lb. of butter. Work it well till it is dissolved; then beat up 2 eggs in a basin, and stir them in. Mix about 1½ pecks of flour with the liquor, and, in winter, make the dough pretty stiff, but more slack in summer; mix it well, and the less it is worked the better. Stir the liquor into flour, as for pie-crust, and after the dough is made cover it with a cloth, and let it lie to rise, while the oven is heating. When the rolls or loaves have lain in a quick oven about a quarter of an hour, turn them on the other side for about a quarter of an hour longer. Then take them out and chip them with a knife, which will make them look spongy, and of a fine yellow, whereas rasping takes off this fine color, and renders their look less inviting.

II. Proceed as for the best bread; use the finest flour, and moisten it with a little milk.

BREAD, FRENCH COUNTRY WHITE This is made without yeast.

BREAD, FRENCH SOUP. This is made by adding 1 lb. or more of salt to each sack, in the place of yeast; and it is baked in thin loaves, so as to be nearly all crust, by which means it becomes more soluble in the hot soup.

BREAD, FROM AMERICAN FLOUR. This flour requires nearly twice as much water to make it into bread, as that made from English wheat, and is therefore much more economical. 14 lbs. of American flour will make 21½ lbs. of bread, but the best sort of English flour produces but 18½ lbs. (Mrs. Rundell.)

BREAD, FROM GRAINS. "Birkenmayer, a brewer of Constance, has succeeded in manufacturing bread from the farinaceous residue of beer. 10 lbs. of this species of paste, 1 lb. of yeast, 5 lbs. of ordinary meal, and a handful of salt, produce 12 lbs. of black bread, both savory and nourishing."

BREAD, (*For one sack.*) Flour 1 sack; salt

4 lbs.; water, sufficient quantity; yeast 4 pints. Dissolve the salt in $3\frac{1}{2}$ gallons of the water, (warm,) then add a little of the flour and the whole of the yeast; make a dough, and keep it in a warm place until it rises, then add more flour and warm water in the same way, and work again; after 3 or 4 hours add the remainder of the flour, and sufficient water to bring the dough to a proper consistence. When the whole mass of dough is in a proper state, it is to be cut into loaves and baked.

Remarks. The bakers employ alum in making their bread, as it not only makes the dough more retentive of moisture, but improves the color of the bread. The proportion is usually 6 or 8 oz. of alum per sack, or even more.

By this process a sack of flour will produce from 345 to 350 lbs. of *well*-baked bread, or if slack-baked, from 370 to 385 lbs. of crumbling bread.

BREAD, HICK'S PATENT. This is merely bread made in the common way, but baked in an oven so arranged that the vapors arising during the process may be condensed in a suitable receiver. The condensed liquor is a crude, weak spirit, produced during the fermentation of the bread. The product will not pay the expense and trouble of the collection.

BREAD, HOUSEHOLD. (*Economical Bread.*) *Prep.* I. Remove the flake bran from the flour, and boil 5 lbs. of it in 4 gallons of water, until it is reduced to $3\frac{1}{2}$ gallons; strain. With this liquor knead 56 lbs. of the flour, adding salt and yeast as for other bread. Bake the loaves for $2\frac{1}{2}$ hours. (Rev. Mr. Haggett.)

II. Mix 7 lbs. of flour with 3 lbs. of mealy potatoes, previously well mashed, add 2 or 3 spoonfuls of salt, and make a dough with water; then well work it with 3 or 4 spoonfuls of yeast, and after 4 hours bake it.

BREAD, IMPROVEMENT OF. A $\frac{1}{2}$ oz. of carbonate of magnesia added to the flour, for a 4 lb. loaf, materially improves the quality of the bread, even when made from the worst new seconds flour. (Professor E. Davy.) This addition is perfectly innocent.

BREAD, ICELAND MOSS. This vegetable may be made into bread, either alone, or mixed with flour. It is used, in the first case, in the state of meal, in the same way as flour; in the second case, 7 lbs. of it are directed to be boiled in 12 or 13 gallons of water, and employed to make 70 lbs. of flour into dough, which is then fermented and baked in the usual way. It is said that the above quantity of flour will produce, in this way, 160 lbs. (?) of good household bread, whereas the same flour, treated in the usual way, would not produce more than 80 lbs. A simpler mode of making this bread, is to mix 1 lb. of lichen meal with $3\frac{1}{2}$ to 4 lbs. of flour. The bitterness of the lichen is extracted by soaking it in cold water.

BREAD, LEAVENED. *Prep.* Take about 2 lbs. of dough of the last making, which has been raised by barm; keep it in a wooden vessel, covered well with flour. This will become leaven when sufficiently sour. Work this quantity into a peck of flour with warm water. Cover the dough close with a cloth, or flannel, and keep it in a warm place; further, mix it next morning with 2 or 3 bushels of flour, mixed up with warm water and a little salt. When the dough is thoroughly made, cover it as before. As soon as it rises, well knead it into loaves. Observe in this process, that the more leaven is put to the flour, the lighter the bread will be, and the fresher the leaven, the less sour will it taste.

BREAD, PARIS WHITE. *Prep.* To 80 lbs. of the dough, before the yeast was added, from yesterday's baking, add as much lukewarm water as will make 320 lbs. of flour into a thin dough; as soon as this has risen, 80 lbs. are to be taken out and reserved in a warm place as leaven for the next baking, and 1 lb. of dry yeast, dissolved in warm water, is to be added to the remaining portion, which is immediately made into loaves, and shortly afterwards baked, the loaves being placed in the oven without touching each other, that they may become crusty all round.

BREAD, POTATO. *Prep.* I. To mealy potatoes, well mashed, add an equal quantity of dough, made with flour, then add a proper quantity of yeast, and mix in as much potato farina, or wheat flour, as will suffice to bring it to a proper consistence. Ferment and bake, as usual.

II. Mix equal parts of potato starch and finely-pulped potatoes, and work them into a dough over night, adding the proper quantity of yeast; the next morning work in the same quantity of potato starch, mashed potatoes, and wheat flour, adding as much hot water as may be required; let it stand to rise, then work it well, cut it into loaves, and in 2 hours put them into the oven.

BREAD, SOURNESS IN. (*To rectify.*) When the dough has become sour from the fermentation proceeding too far, or the flour being of inferior quality, the addition of about a $\frac{1}{4}$ oz. of carbonate of magnesia, or a little carbonate of soda, will remove it. When it arises from the sourness of the yeast, this method is especially applicable.

BREAD, STEAM-BAKED, (*à la Vienne.*) It has been known for some time at Vienna, that if the hearth of an oven be cleaned with a moistened wisp of straw, bread baked therein immediately afterwards presents a much better appearance, the crust having a beautiful yellow tint. It was thence inferred that this peculiarity must be attributed to the vapor, which being condensed on the roof of the oven, fell back on the bread. At Paris, in order to secure with certainty so desirable an appearance, the following arrangement is practised:—The hearth of the oven is laid so as to form an inclined plane, with a rise of about 11 inches in 3 feet, and the arched roof is built lower at the end nearest the door, as compared with the farthest extremity. When the oven is charged, the entrance is closed with a wet bundle of straw. By this arrangement the steam is driven down on the bread, and a golden-yellow crust is given to the bread, as if it had been previously covered with the yelk of an egg. (Hbgen Correspondent, Sept. 27. Ann. of Chym. and Prac. Pharm.)

BREAD, TO SWEETEN, (WITHOUT SUGAR.) It is not generally known that pure starch added to flour and made into dough, will be partially converted into a species of sugar during the process of fermentation and baking, and produces sweet wholesome bread. From the experiments of Dr. Colquhoun, it appears that starch arrowroot, farina of potatoes, or similar amylaceous substances, made into a jelly with hot water, may be

employed for this purpose with advantage. It is only necessary to mix the flour up with the jelly, instead of mere water, to add yeast and salt, and to bake in the common way. Dr. Percival has recommended the addition of salep for this purpose. 1 oz. of salep dissolved in 1 quart of water; 2 lbs. of flour; 80 grains of salt, and 2 oz. of yeast, gave 3 lbs. 2 oz. of good bread; but the same weight of materials, without the salep, gave only 2¾ lbs. If too much salep be added, however, it will give its flavor to the bread.

BREAD, WHITING'S, (PATENT.) This is made by dividing the dough into two portions; to the one a little carbonate of soda is added, to the other, a little dilute muriatic acid; they are both well kneaded separately, then mixed together, formed into loaves, and baked immediately. No yeast is used.

BREATH, FŒTID. Scarcely any thing is more disagreeable or disgusting than a stinking breath. Various means have been proposed to remove this annoyance, depending principally on the administration of aromatics, which by their odor might smother it for a time; but these require continual repetition, and are liable to interfere with the functions of digestion. The real cause of a stinking breath is either a diseased stomach or carious teeth; when the former is the case aperients should be administered; and if these do not succeed, an emetic may be given, followed by a dose of salts, or castor oil occasionally. When rotten teeth are the cause, they should be removed; or, if this be impossible, they should be kept clean. Dirty teeth often cause the breath to smell. The use of the tooth-brush should be a daily habit. Occasionally rinsing out the mouth with a little clean water, to which a few drops of a solution of chloride of lime, or chloride of soda, has been added, is an effective method. The following lozenges have also been recommended:—

Gum catechu 2 oz.; white sugar 4 oz.; orris powder 1 oz.; make them into a paste with mucilage, and add a drop or two of neroli. One or two may be sucked at pleasure.

BREAKFAST POWDER. *Syn.* RYE COFFEE. DILLENIUS'S DITTO. HUNT'S ECONOMICAL BREAKFAST POWDER. Rye roasted along with a little fat. *Use.* As a substitute for foreign coffee, of which it is one of the cheapest and best.

BREE'S ANTI-ASTHMATIC PLASTER. *Prep.* Simple diachylon 1 oz.; powdered camphor and powdered opium, of each ¼ oz.; sweet oil ½ a teaspoonful. *Proc.* Melt the plaster with the oil, then remove the vessel from the fire, and stir in the powders; spread it on leather before it gets cold. *Remark.* It is better made with only half the above quantity of opium.

BREWING. The art of making beer.

General notice. Before entering on a description of the process of brewing, it will be necessary to notice the apparatus and materials required for its conduct.

The apparatus consists of,

1. *A copper or boiler* capable of holding fully two-thirds of the quantity proposed to be brewed; with a gauge-stick to determine the number of gallons of fluid at any given depth therein. A copper holding about 140 gallons is a convenient size for brewing a quarter of malt.

2. *A mash-tub,* or *tun,* capable of containing rather more than the copper.

3. *One or more tuns, or vessels,* to ferment the beer in.

4. *Three or four shallow coolers* to reduce the wort as rapidly as possible to a proper temperature for fermenting.

5. *One or two copper or wooden bowls,* for bailing, &c.

6. *A thermometer* with a scale reaching from zero to above the boiling point of water.

7. *A suitable number of casks* (clean) to contain the beer.

8. *One or more large funnels, or tunners.*

9. *Two or more clean pails.*

10. *A hand-pump* of a size proportionate to the brewing.

These articles will vary in value from £10 upwards, to many hundreds, according to the extent of the brewing; but the whole of them, necessary for a private family, may be bought for less than the former amount. By proper care they will last for 30 or 40 years, and still be in a useful state. The place where these vessels are kept, and the operations carried on, is called the "*Brewhouse.*"

The materials necessary to brew beer are, *good malt, hops,* and *water,* and a little *yeast.*

The *malt* is bruised or crushed in a mill before brewing, that it may be acted on the more readily by the water. It should not be ground too small, as it would then make the wort thick; the crushed malt may advantageously lie for a few days in a cool situation, by which it will attract a considerable quantity of moisture from the air, and consequently its soluble portion will be the more easily dissolved out by the water used in mashing. Pale malt may be used coarser than amber or brown malt. A bushel of malt should make a bushel and a quarter when ground, and a quarter should yield between 9½ and 10 bushels, the quantity slightly varying according to the degree of bruising it has undergone. On the large scale, malt is ground in crushing mills, furnished with iron rollers; and on a small scale, by wooden rollers or small mills worked by hand. For private brewing, the malt is generally bought ready ground, for convenience sake. (See MALT.)

The hops should be those of the previous season, and for general purposes grown in Kent; but for the finer sorts of malt liquor, East Kent hops should be used; and where it is intended to be kept for some long time, those known by the names of *Country's, Alton's,* or *Farnham Hops* must be employed. The quantity of hops required to a given measure of malt varies from 2 lbs. to 8 lbs. of the former, to 1 quarter of the latter, according to the nature of the brewing. For good strong beer, 4 lbs. or 4½ lbs. is usually sufficient, but when the liquor is very strong, and it is intended to be highly aromatic, and to be kept for a long period, 1 lb. of hops may be used to every bushel of malt, or 8 lbs. to the quarter. Mild porter has about 3 lbs. to the quarter, and weak common beer has frequently only about ¾ lb. of hops to the bushel of malt. A portion of hops is also frequently added to the finer sort of beer, after it is casked, as we shall presently explain.

The water should be *soft* and *clear,* the *yeast sweet* and *good,* and all the vessels and casks both

sweet and *clean*. If this be not the case, with the latter especially, the best brewing in the world will be useless.

PROCESS OF BREWING. This may be divided into

I. *The mashing*. This operation consists in placing the ground or bruised malt in a large tub or "*tun*," known by the name of the "*mash-tun*," macerating it for some time in hot water, and lastly drawing off the wort from a hole in the bottom, over which a bunch of straw, or a strainer, or false bottom, is placed, to prevent the malt passing out along with the liquor. During the process of mashing, a peculiar principle, called by chemists *diastase*, reacts upon the starch also contained in the malt, and converts it first into a species of gum, called by the French chemists "*dextrine*," and then into a species of sugar resembling that produced by the action of sulphuric acid. The greater the quantity of starch converted into sugar in this way, the stronger and finer will be the wort. It therefore becomes a desideratum with the brewer to mash at a temperature that will most fully promote this object. It has been found that the best temperature for this purpose varies from 157° to 160°, but when more than one liquor is used, the first should be something lower than the former, the next may be between the two, and the third may slightly exceed the latter, or be about 165° or 170°. The action of the first mash is merely to extract the sugar contained in the malt already formed; that of the second to convert the starch into sugar by the action of the diastase; the third to fully complete this object, as well as to carry away the remaining portions of extract.

The mashing is usually performed by filling the copper with water, and as soon as it acquires the temperature of 145° in summer, or 167° in winter, 45 gallons are run off into the mash-tun, and 1 quarter of crushed malt gradually thrown in and well mixed by laborious working, until it becomes thoroughly incorporated and no lumps remain; the agitation is then continued for 30 or 40 minutes, when 36 gallons of water from the boiler, at a temperature of 200°, are added, and the whole again well agitated until thoroughly mixed. The mash-tun is now closely covered up, and allowed to stand for an hour or an hour and a half. At the end of this time the tap is set, and the wort is drawn off into the "underback," and generally amounts to about 50 to 52 gallons: 60 gallons of water, at a temperature of 200°, are next added to the mash-tun, previously drained well, and after being well worked, the whole is covered up as before. This mash is allowed to remain for an hour, when it is drawn off, and the malt again drained ready for the third mash. This time only 35 gallons of water are added at 200°, and allowed to stand for ½ an hour, when it is run off in the same manner as before, and the malt allowed to drain. The worts are now ready for boiling.

In some cases only the first and second mash is used for strong beer, and the third kept for table, or as water to mash a fresh quantity of malt with. In Scotland (see SCOTCH ALE) the brewer only mashes *once*, and afterwards washes his malt by frequent showers or "sparges" of water, by which he gets a wort of greater strength in proportion to its quantity. In operating as above, the average or mean temperature of the first mash is 145°, of the second 170°, and of the third 180°. In winter the mean temperature may be reckoned as 6 or 7° lower. A quarter of malt in this way will produce a wort having a specific gravity by the saccharometer of 1·234, or equal to 84 lbs. of extract. (See SACCHAROMETER.)

It is calculated that 32 gallons of the water employed in the mashing remain in the grains after the wort is drawn off.

II. *Boiling*. The wort is next transferred to the copper, and heated to the boiling point as soon as possible. In large breweries where several coppers are employed, the first mash is no sooner run into the underback, than it is transferred to the wort copper, and immediately boiled, and the successive mashings added as soon as drawn off; but in private houses, where there is only one copper, the boiling cannot be commenced until the water for the last mashing is removed. In some cases the worts are brewed separately, thus producing 2 or 3 qualities of beer, viz. *strong ale or stout, beer, and table beer*. No sooner has the boiling commenced than the hops may be added, and the boiling continued for 2 or 3 hours or more. In some breweries the beer is boiled for several hours, and in Belgium it is said that this is even continued for 10 or 12 hours, but too much boiling drives off the flavor of the hops. In general, two hours good boiling will be found sufficient. In small brewings the first wort should be sharply boiled for 1 hour, and the second for 2 hours. But if intended for beer of long keeping, the time should be extended half an hour. The hops should be strained from each preceding wort, and returned into the copper with the succeeding one. Between the boilings the fire should be damped with wet cinders, and the copper door set open.

For small-beer only half an hour is necessary for the first wort, 1 hour for the second, and 2 hours for the third.

It is reckoned that $\frac{1}{8}$ to $\frac{1}{18}$ part of the wort is dissipated in steam during the process of boiling, but this must of course depend altogether on the evaporative power of the boiler and the length of time the boiling is continued.

III. *Cooling*. The boiling being finished, the wort is run off from the copper into the hopback, which is furnished with a strainer to keep back the hops. It is then pumped into large square shallow vessels called "*coolers*," where it is exposed to a good current of air to cool it down to a proper fermenting temperature as quickly as possible. This is of the utmost importance for the success of the brewing. The wort should be laid so shallow as to cool within 6 or 7 hours to the temperature of about 60°. In warm weather, the depth should not exceed 3 or 4 inches; but in cold weather it may be 5 or 6 inches. As soon as the heat has fallen to about 60°, it should be instantly tunned and yeasted.

It is reckoned that by the joint evaporation from the boilers and coolers, there is a loss of about 40 gallons per quarter.

In private families a good way is to bring the wort from the copper in pails, and to pour it into a basket or a hamper, set over the coolers, by which means the hops will be retained, and the beer run through clear.

IV. *Fermentation.* When the wort is sufficiently cool, it is run into the fermenting tuns or vessels, which in small brewings may be casks, with one of their heads removed. These are called "*gyle tuns,*" and should not be more than $\frac{3}{4}$ full. The yeast, previously mixed with a little wort, and kept until this latter has begun to ferment, may now be added, and the whole agitated well; the tun should then be covered up, until the fermentation is well established. During this process the temperature rises from 9° to 15°.

The quantity of yeast employed, and the temperature of the wort when it is added, differ in different breweries and for different kinds of beer. From $\frac{1}{2}$ to $1\frac{3}{8}$ of yeast, taken from a previous brewing of the same kind of beer, is the quantity usually employed. The higher the temperature the less yeast necessary. In England, the temperature at which the yeast is usually added, varies from 55° to 65° Fahr. In cold weather, the heats in the coolers should be 5° or 6° higher than in mild and warm weather. For ale, in cold weather, it should be tunned as soon as it has fallen to 60° in the coolers. For porter, to 64°, and for table beer to 70°; and in warm weather, strong beer should be 4° or 5° less, and table beer 7° or 8°. Care should be also taken that the worts do not get cold before the yeast is mixed to produce fermentation. The common rule for mixing the yeast is $1\frac{1}{2}$ lbs. to every barrel of strong beer wort, and 1 lb. to every barrel of table beer wort.

The commencement of the fermentation is indicated by a line of small bubbles round the sides of the tun, which, in a short time, extends over the surface. A crusty head follows, and then a fine rocky one, followed by a light frothy head. In the last stage, the head assumes a yeasty appearance, and the color is yellow or brown, the smell of the tun becoming strongly vinous. As soon as this head begins to fall, the tun should be skimmed, and the skimming continued every two hours till no more yeast appears; this closes the operation, and the beer should then be put into casks, or, in technical language, "*cleansed.*" A minute attention to every stage of this process is necessary to secure a fine flavor and a brilliant beverage.

In Scotland the temperature at which the yeast is added, is generally much lower than in England; for ale, it is from 51° to 52°, and the whole process is conducted in the cooler part of the year, so that the temperature seldom rises higher than 65° or 66°. The Bavarian beer, so much celebrated on the continent, as well as the finest kinds of East India ale, are fermented at very low temperatures.

It may be generally regarded as a rule, that the lower the temperature, and the slower, more regular and less interrupted the process of fermentation, the better will be the product and the less likely to change by age. More yeast is required in winter than in summer. Should the fermentation become slack in the gyle-tun, a little more yeast is frequently added, and the whole is roused up; but on the contrary, should the temperature rise considerably, or the fermentation become too active, the wort should be cooled a little and skimmed, or at once cleansed.

V. *Cleansing.* When the fermentation has proceeded to a certain extent, the liquor undergoes the operation called "cleansing." This consists in drawing it off from the gyle tun into other vessels, or casks, set sloping, so that the yeast, as it forms, may work off the one side of the top, and fall into the vessel placed below to receive it. In small brewings, the beer is often at once transferred from the gyle tun to the store casks, which are sloped a little until the fermentation is over, when they are skimmed, filled, and bunged up. When the operation of cleansing is not employed, the yeast is removed from the surface of the gyle tun with a skimmer, and the clear liquor drawn off into the store casks.

The process of cleansing should always commence as soon as the gravity of the liquor falls to 10 or 11 lbs. per barrel, which it usually does in about 48 hours, provided the fermentation has been well conducted. Some brewers add $\frac{1}{4}$ to $\frac{1}{2}$ lb. of wheat or bean flour to the beer in the gyle-tun, shortly before cleansing, to quicken the discharge of yeast, but it is not clearly ascertained whether such a plan be advantageous or the contrary.

VI. *Storing.* As soon as the fermentation is concluded, which generally takes from 6 to 8 days, or more, the clear liquor is drawn off into the store casks, or vats, which are then closely bunged down, and deposited in a cool cellar.

VII. *Ripening.* After a period, varying from 1 to 12 months, or more, according to the nature of the brewing, the liquor will have become fine, and sufficiently ripe for use. All the attention required during this interval, is to look occasionally to see that there is no leakage, and to open the vent holes, should any oozings appear between the staves of the casks.

VIII. *Fining.* It frequently happens that malt liquor, especially porter, with all the care bestowed upon it in brewing, will not turn out sufficiently fine to meet the taste and eye of the consumer, in which case it is usually subjected to the operation of "*clarifying.*" For this purpose 1 oz. of isinglass is put into 1 quart of weak vinegar, or still better, hard beer, and when dissolved, a sufficient quantity of good beer may be added to make it measure 1 gallon. This mixture is called "finings;" 1 to 2 pints of which is the proper quantity for a barrel. The method of using it, is to put the finings into a bucket, and to gradually add some of the beer, until the bucket is three parts full, during which time it is violently agitated with a whisk, and this is continued until a good frothy head is raised upon it, when it is thrown into the barrel of beer, and the whole well rummaged up, by means of a large stick shoved in at the bunghole. In a few days the beer will usually become fine.

In some bad sorts of beer isinglass will have no effect. This may be ascertained beforehand, by trying some in a long glass tube, or vial, with a little of the finings. These should be well shaken together, and then set aside for a short time, when it will be found that the finings will rise to the top, leaving the central portion of the beer clear, if it be in a proper condition for clarifying; but if, on the contrary, they sink to the bottom, and the liquor still keeps foul, no quantity of finings, how-

ever great, will ever clarify it. This latter defect may be remedied by proceeding to fine it after the manner above described, and then adding, *after* the finings have been well rummaged up, either 1 spoonful of oil of vitriol, or gum catechu, dissolved in ½ a pint of warm water, again rummaging well for a quarter of an hour. Or 1 or 2 oz. of tincture of catechu may be used instead, mixed with a little water. Either of these additions acts chemically on the finings, in the same way as good beer does, precipitating them along with the foulness, and thus brightening the liquor. The addition of a handful of hops, previously boiled for 5 minutes in a little of the beer, and then added to the barrel, and the whole allowed to stand for a few days, before proceeding to clarify it, will generally have the same effect.

Concluding Remarks. *The nature and varieties of beer, &c.* The numerous varieties of beer met with in commerce, arise either from a difference in the materials, or the management of the brewing. Thus the *water*, but more generally the nature of the malt, or the temperature of the mashing or the fermentation, decides the character of the liquor. The difference between ale and porter arises from the color of the malt, and the distinctions between the same class of liquor, brewed from similar materials, may be referred to the mashing or the fermentation. Scotch ale and Bavarian beer differ in style from other ales, as before explained, from being fermented at lower temperatures; and porter differs from either of these, because it has been made with higher dried malt. This is the cause of the almost endless varieties of malt liquor met with in England. Every country—nay, every town and every brewer, is distinguished by the production of a different flavored beer. Besides the varieties arising from difference of quality or manipulation in the brewing of similar kinds of liquor, there are certain leading features which distinguish some of them, which has led them to be considered in the light of distinct members of the same family. These are *ale*, *beer*, and *porter*. *Ale* is a pale liquor, brewed from lightly-dried malt, and is usually met with, abounding in undecomposed saccharine matter and mucilage; *beer* is a fine, strong, well-fermented liquor, darker, less saccharine, and more alcoholic than ale. The finer class of Scotch, Bavarian, and East India ales, properly belong to this class; *porter* is a dark brown colored liquor, originally prepared from high-dried malt, but now generally made from pale malt, and colored and flavored by patent or burnt malt. *Small or table beer* is a weak liquor, containing 3 or 4 times the quantity of water that is used for ordinary beer. *Stout, brown stout*, &c. are varieties of porter, differing only in their strength. See Ale, Beer, and Porter, in their alphabetical order.

Qualities. The characteristics of good beer are transparency and a fine color, to whatever variety it may belong; and if it has been properly brewed, this will usually be the case. Hence color and transparency become a proof of good beer. Good beer is pleasant, wholesome, and nutritious, at the same time that it is strengthening and exhilarating.

Season for brewing. The best times of year for brewing are the spring and autumn, as at those periods the temperature of the air is such as to permit the cooling of the worts sufficiently low, without having recourse to artificial refrigeration, or the use of machinery for that purpose.

Adulteration. Laws respecting brewing, &c. By the laws of England, which have existed, with slight modifications, ever since the days of Queen Anne, *nothing* is allowed to enter into the composition of beer but malt and hops. The cupidity of the fraudulent brewer has, however, frequently induced him to introduce other ingredients with the view of imparting a false strength to his liquor, or as a substitute for one or other of its constituents. Thus, *to impart bitterness*, and to lessen the quantity of hops required for the beer, *quassia, gentian, wormwood*, and *broom-tops* have been used; *to give pungency and flavor, capsicum, and grains of paradise*, (in concentrated tinctures,) *ginger, corianders, orange-peel, and caraways;* to give *intoxicating properties—opium, cocculus indicus, nux vomica, tobacco, extract of poppies and tincture of henbane;* as a *substitute for malt—molasses, coloring and sugar;* to impart a *false appearance of age—sulphuric acid, alum, green vitriol*, and *common salt*. The following is a list of the unlawful substances seized at different breweries, and brewers' druggists' laboratories in London, as copied from the minutes of the committee of the House of Commons. "*Cocculus indicus, multum*, (*an extract of the cocculus*,) *coloring, honey, hartshorn shavings, Spanish juice, orange powder, ginger, grains of paradise, quassia, liquorice, caraway seeds, copperas, capsicum, mixed drugs.*"

Sugar and coriander seeds may be mentioned as a very common addition to beer. It is said that 6 lbs. of the former, and 1 lb. of the latter, are equal in strength and intoxicating quality to a bushel of malt. The sugar is employed in a roasted state, for the sake of its color; even coffee has been used for this purpose. *Publicans* generally reduce their strong beer with water, or table beer, and add treacle, (which they call "*foots*,") and a mixture of copperas, salt, and alum, (which they call "*heading*,") to make it bear a frothy head, and in many cases, gentian, sugar, or other similar ingredients, are added to keep up an appearance of strength, and to impart a flavor.

The "*cheap beer*" sold by some taverns in London, is made by dividing the contents of *two* butts among *three* butts, filling them up with water, and adding a bladder of *porter extract* (technically termed P. E.) to each.

The desire of evading the duty on malt, led to the discovery of its being only necessary to malt ⅓ or less of the grain, this portion being sufficient to convert the starch of the other part into sugar, in the process of mashing. This plan answers well when the wort is merely intended for the production of "*grain spirit*," but beer so made is inferior in quality to that brewed wholly from malt. Inferior kinds of beer have also been made from other ingredients than barley malt; thus, the grain of other cereals may be used for this purpose, as wheat, oats, &c., and many other vegetable substances that contain starch and sugar. *Potatoes, turnips, beet root, carrots, parsnips*, and other similar roots and seeds, will all produce beer by peculiar management, but the liquor must be con-

fined to private consumption, as the law does not permit its sale. Some of the above articles produce very wholesome beer, if mashed with about $\frac{1}{10}$ or $\frac{1}{12}$ of their weight of good barley malt.

The densities of the worts employed for different kinds of beer vary considerably, as will be seen by the following table.

TABLE exhibiting the densities of different kinds of Beer.

Description.	Pounds per Barrel.	Specific Gravity.
Burton Ale, 1st Class	40 to 43	1·111 to 1·120
Do. 2d "	35 to 40	1·097 to 1·111
Do. 3d "	28 to 33	1·077 to 1·092
Ordinary Ale . . .	25 to 27	1·070 to 1·073
Common Ale . . .	21	1·058
Scotch Ale, 1st Class	40 to 44	1·111 to 1·122
Do. 2d "	33 to 40	1·092 to 1·111
Porter (ordinary) . .	18	1·050
Do. (good) . . .	18 to 21	1·050 to 1·058
Do. (double) . . .	20 to 22	1·055 to 1·060
Brown Stout . . .	23	1·064
Do. (best) . . .	26	1·072
Table Beer	12 to 14	1·033 to 1·039
Table Beer (common)	6	1·014

BREWING UTENSILS, TO CLEAN AND PRESERVE. In cleaning them before being put away, avoid the use of soap, or any greasy material, and use only a brush and scalding water, being particularly careful not to leave any yeast or fur on the sides, then place them away in a clean, and moderately dry situation. Should they become tainted or mouldy, take a strong lye of pearlash, which spread over the bottoms of the vessels scalding hot, and then with the broom scrub the sides and other parts.

Or, take common salt and spread it over the coolers, &c., and strew some on their wet sides, turn in scalding water and scrub them with a broom.

Or, throw some quicklime into water in the vessel, and scrub over the bottom and sides with it; in each case well washing afterwards with clean water.

Or, wash well first with oil of vitriol diluted with 8 times its weight of water, and afterwards with clean water.

Remarks. Brewing utensils with care will last for many years. Mr. Cobbett says: "I am now in a farm-house, where the *same* utensils have been used for *forty years;* and the owner tells me that they may last for *forty years longer.*"

BRINE, RED CABBAGE. *Prep.* Steep red cabbage leaves in a strong solution of salt. *Use.* As a test for acids and alkalis.

BRINE, VIOLET. *Prep.* The same as the above, but made from the petals of the blue violet.

BRIOCHE PASTE, (IN COOKERY.) *Prep., &c.* A paste made of eggs and flour, fermented with a ttle yeast, to which a little salt, a large quantity of sugar, and half as much butter as the weight of the flour used, are afterwards added and well worked in. *Use.* As an addition to soup, a casing for lobsters, patties, eggs, &c.

BRITANNIA METAL. *Syn.* TUTANIA. A fine species of pewter.

Prep. Melt together equal parts of plate brass, bismuth, antimony, and tin, and add the mixture at discretion to melted tin, until it acquires t proper degree of color and hardness.

II. To the last add an equal part, or ½ of i weight of metallic arsenic. To be used as befo

III. Melt together 1 part of antimony, 4 par of brass, and 5 or more parts of tin. This may used at once, as Britannia metal. (See PEWTER

BRITISH GUM. When starch is exposed a temperature of 300°, (Ure,) 600°, (Brande,) becomes brown, soluble in cold water, and ceas to strike a blue color with iodine. It is large employed by the calico printers, as a substitute f gum.

BRISTLES AND HORSE HAIR, TO DYE. These readily take any of the usual dyes applied to cotton or wool.

BROMAL. A compound discovered by Löwig, produced by the action of bromine on alcohol, hence the name, from the first portion of the name of each constituent. (See CHLORAL.)

BROMATES. Compounds of the bases with bromic acid, which see. *Char., Tests, &c.* When heated they evolve oxygen, and become bromides; with nitrate of silver and the proto-salts of mercury, they give white precipitates; that with the former is insoluble in nitric acid, but very soluble in ammonia. If a few drops of muriatic acid be added to a bromate, and it be then shaken with a little ether in a glass tube, a solution of bromine is obtained.

BROMBENZOIC ACID. A new acid, discovered by Peligot, and prepared by exposing benzoate of silver to the vapors of bromine, until they cease to be absorbed, when the acid is dissolved out with ether and obtained by evaporation.

BROMIC ACID. An acid composed of oxygen and brome.

Prep. Add sulphuric acid to a solution of bromate of baryta, until all the earth be thrown down, particularly avoiding an excess of acid; then concentrate the liquor by heat, until it be of the consistence of a sirup.

Prop. If the evaporation be carried too far, the acid will be decomposed. This acid forms salts with the bases, called bromates, which are very similar to the chlorates and iodates. *Bromate of potassa* may be made by agitating bromine with a concentrated solution of caustic potassa, collecting the crystalline white powder that falls down, and purifying it by solution in boiling water, and crystallization. *Bromate of silver* is formed by adding a solution of bromate of potassa to another of nitrate of silver.

BROMIDE. A compound form of a base and bromine. (See BROMINE.)

Char. and Tests. The soluble bromides give white precipitates with nitrate of silver, acetate of lead, and protonitrate of mercury. That from the first of these is insoluble in ammonia water, unless concentrated. A few drops of liquid chlorine poured upon a bromide, and the mixture agitated with a little sulphuric ether, yields an ethereal solution of bromine.

BROMIDE OF AMMONIA, may be formed by the mixture of ammoniacal and hydrobromic acid gases, or liquid hydrobromic acid and liquor of ammonia, or by putting bromine into water of ammonia.

Prep. This salt may be obtained by evaporation

in the form of solid white prismatic crystals. It is volatile and easily decomposed.

BROMIDE OF CARBON. (Discovered by M. Serullas.) *Prep.* Brome 2 parts; periodide of carbon 1 part, mix; just enough solution of potassa is added to make the liberated iodine disappear. The liquid bromide of carbon, which collects at the bottom of the solution, is then separated from the supernatant portion, and allowed to stand until it becomes clear. A few crystals of iodide of potassium rise to the surface, and may be removed. The clear liquid is then put into a little water slightly alkalized with potassa, to remove a little remaining iodide of carbon, after which it is quite pure.

BROMIDE OF IODINE. Bromine and iodine unite rapidly by mere mixture. By careful distillation a red vapor is obtained, which, on cooling, condenses into red crystals, of a form resembling fern leaves. This is said to be the *protobromide.* By adding more bromine, these crystals are converted into a fluid, said to be the *bibromide.*

BROMIDE OF SULPHUR. This is made by dissolving sublimed sulphur in bromine; it is a reddish, oily-looking fluid, easily decomposed, especially by water.

BROMINE. *Syn.* BROME. An elementary substance, discovered by M. Balard, of Montpellier, in 1826.

Prep. A current of chlorine is passed through the uncrystallizable residuum of sea-water, called *bittern,* which then assumes an orange tint, in consequence of bromine being set free from its combinations; sulphuric ether is then agitated with it, and the mixture is allowed to stand until the ethereal portion, holding the bromine in solution, floats upon the surface. This is then carefully decanted, and agitated with a solution of potassa, by which means bromide of potassium and bromate of potash are formed.

The whole is next evaporated to dryness, and submitted to a dull red heat; the residuum is then powdered, mixed with pure peroxide of manganese, and placed in a retort; sulphuric acid, diluted with half its weight of water, is now poured in. Red vapors immediately arise, and condense into drops of bromine, and are collected by plunging the neck of the retort to the bottom of a small receiver, containing cold water. The bromine forms a stratum beneath the water, and may be collected and further purified, by distillation from dry chloride of calcium.

Prop., Use, &c. A dark, reddish-colored liquid, having an odor resembling chlorine. It freezes at —4°, boils at 116·5°, is about 3 times as heavy as water, is very soluble in ether, less so in alcohol, and only slightly so in water. With hydrogen it forms hydrobromic acid, and with the bases, compounds called bromides, or hydrobromates. It possesses similar medicinal properties to iodine, and has been administered in goitre, scrofula, &c., in the form of an aqueous solution, composed of 1 part of bromine to 4 of water; 5 or 6 drops being the dose. This solution has also been used as a lotion.

Tests and Antidotes. The solution of chloride of gold gives a red tinge with hydrobromic acid, or an electro-positive hydrobromate.

When bromine exists in an organic mixture, caustic potassa should be added to the mass, which should then be reduced to an ash, exhausted by distilled water, and chlorine passed through the solution, or the chloride of gold added to it, previously carefully neutralized by hydrochloric acid. When chlorine is used, starch may render the presence of the element more perceptible. Nitrate of silver is also a delicate test, where the bromine is not mixed with chlorine; the bromide of silver is distinguished from the chloride by heating with hydrochloric acid and chlorite of lime, when ruddy fumes are evolved, if bromine is present.

M. Barthez has proposed magnesia as an antidote for bromine. From several experiments, it appears that the bromide of magnesium is by no means an active salt; neither is it inert. From experiments performed on rabbits, I conclude starch in solution, and white of egg, to be excellent antidotes to the poison. (Dr. Glover, Med. and Sur. Jour., No. 152.)

BROMINE, CHLORIDE OF. *Prep.* Transmit a current of dry chlorine through brome, and condense the disengaged vapors in a receiver surrounded with ice. *Prop.* A volatile reddish fluid, soluble in water, without decomposition.

BRONCHITIS. An inflammation of the mucous lining of the bronchia, or smaller ramifications of the windpipe. In its milder form it is commonly called "*a cold on the chest.*"

Symp. Hoarseness, dry cough, a slight degree of fever, followed by expectoration of mucus, at first thin, and afterwards thick and copious. In the severer forms, there is more fever, cough, and oppression at the chest, &c.

Treat. The generality of cases of bronchitis yield to small and repeated doses of ipecacuanha, and antimonial diaphoretics, at the same time adopting a light diet, and keeping the bowels open with mild purgatives.

BRONZE. A metallic alloy, composed principally of tin and copper, remarkable for the exactness of the impressions which it takes by moulding, as well as its durability; and hence, extensively employed in the casting of busts, medals, and statues. Bell, cannon, and speculum metal are varieties of bronze. In ancient times, when the manufacture of steel was ill-understood, cutting instruments were frequently made of this alloy. For statuary work, the great desideratum is to obtain an alloy capable of flowing freely into the most minute outlines of the mould, hard, and yet tough, and capable of resisting the corroding action of the weather. It must also acquire that peculiar antique green appearance, that is so much admired in bronzes.

When only a small quantity of the alloy is required, it is prepared in crucibles, but for statues or larger works, on reverberatory hearths. The fusion of the mixed metals must be conducted under pounded charcoal, and as rapidly as possible. When melted, it must be frequently stirred together to produce a perfect mixture, before casting. Coal is the fuel principally employed for the furnaces.

The proportions of the materials so vary in different castings, that it is almost impossible to say precisely what quantities are the best. The following may be regarded as good specimens. (See also CANNON, BELL, and SPECULUM METAL.)

BRONZE, (FOR STATUARY.) I. Copper 88 parts; tin 9 parts; zinc 2 parts; lead 1 part.

II. Copper 82½ parts; tin 5 parts; zinc 10½ parts; lead 2 parts. These are very nearly the proportions in the celebrated statue of Louis XV.

III. Copper 90 parts; tin 9 parts; lead 1 part.

IV. Copper 91 parts; tin 9 parts.

BRONZE, (FOR MEDALS.) I. Copper 89 parts; tin 8 parts; zinc 3 parts. *Remarks.* This metal assumes a beautiful antique appearance by age, and takes a good impression by stamping.

II. Copper 95 parts; tin 4 or 5 parts. These are the proportions recommended by M. Chaudet, who casts it in moulds made of bone-ash, like cupels, and afterwards finishes and polishes the medals in a coining press. This is also excellent for any small castings.

BRONZE, (FOR CUTTING INSTRUMENTS.) Copper 100 parts; tin 14 parts.

Remarks. M. Dussaussy says that the above alloy, when hardened and tempered after the manner of the ancients, will yield an edge nearly equal to that of steel. Several analyses have been made of ancient cutting instruments, whence it appears that the proportion of tin varies from 4 to 15 per cent., which tends to prove that more depends on the exact mode of tempering the alloy, than on the relative quantities of the ingredients. Zinc and tin are inadmissible in bronze for this purpose. One or 2 per cent. of iron might, nevertheless, be added with advantage. The ancient bronze used for springs, contained only 3 to 4 per cent. of tin.

BRONZE, (FOR MORTARS.) Copper 93 parts; lead 5 parts; tin 2 parts.

Remarks. The edges and lips of mortars must be tempered by heating them to a cherry red, and then plunging them into cold water; as unless so treated, they are very apt to be broken.

BRONZE, (FOR ORNAMENTAL WORK, TO BE GILDED.) I. Copper 82 parts; zinc 18 parts; tin 3 parts; lead 2 parts.

II. Copper 83 parts; zinc 17 parts; tin 1 part; lead ½ part.

BRONZE POWDERS. I. (*Beautiful red.*) *Prep.* Mix together sulphate of copper 100 parts; carbonate of soda 60 parts; apply heat until they unite into a mass, then cool, powder, and add copper filings 15 parts; well mix, and keep them at a white heat for twenty minutes, then cool, powder, and wash and dry.

II. (*Gold colored.*) *Prep. a.* Verdigris 8 oz.; tutty powder 4 oz.; borax and nitre, of each 2 oz.; bichloride of mercury ¼ oz.; make them into a paste with oil, and fuse them together. *Used* in japanning as a gold color.

b. Dutch leaf reduced to an impalpable powder by grinding.

III. (*Iron colored.*) Plumbago finely powdered.

IV. (*Silver white.*) *Prep.* Melt together 1 oz. each of bismuth and tin, then add 1 oz. of running quicksilver; cool and powder.

BRONZING OF MEDALS, AND ORNAMENTS OF COPPER, ELECTROTYPES, &c. *Proc.* I. Having thoroughly cleaned and polished the surface of the specimen, with a brush apply the common crocus powder, previously made into a paste with water. When dry, place it in an iron ladle, or on a common fire-shovel, over a clear fire for about 1 minute; and when sufficiently cool, polish with a plate-brush. By this process a bronze similar to that on tea-urns is produced; the shade depending upon the duration of the exposure to the fire. (Chemist, iii. 49.)

II. By substituting finely-powdered plumbago for crocus powder in the above process, a beautiful, deep, and permanent bronze appearance is produced.

III. Rub the medal with a solution of livers of sulphur, or sulphuret of potassium, then dry. This produces the appearance of *antique* bronze very exactly.

IV. Dissolve 2 oz. of verdigris and 1 oz. of sal ammoniac in 1 pint of vinegar, and dilute the mixture with water until it tastes but slightly metallic, when it must be boiled for a few minutes, and filtered for use. Copper medals, &c., previously thoroughly cleaned from grease and dirt, are to be steeped in the liquor at the boiling point, until the desired effect is produced. Care must be taken not to keep them in the solution too long. When taken out, they should be carefully washed in hot water, and well dried. *Gives an antique appearance.*

V. (*Chinese method.*) Make a paste with 2 oz. each of verdigris and vermilion; 5 oz. each of alum and sal ammoniac, all in fine powder, and vinegar q. s.; then spread it over the surface of the copper, previously well cleaned and brightened, uniformly warm the article by the fire, and afterwards well wash and dry it, when, if the tint be not deep enough, the process may be repeated. The addition of a little blue vitriol inclines the color to a chesnut brown, and a little borax to a yellowish brown. Much employed by the Chinese for copper tea-urns.

VI. Dissolve 1 oz. of sal ammoniac, 3 oz. cream of tartar, and 6 oz. of common salt, in 1 pint of hot water; then add 2 oz. of nitrate of copper, dissolved in ½ a pint of water; mix well, and apply it repeatedly to the article, placed in a damp situation, by means of a brush moistened therewith. *Effect.* Very antique.

VII. Salt of sorrel ¼ oz.; sal ammoniac 1 oz.; distilled vinegar 2½ pints; dissolve. As last.

BRONZING, SURFACE. This term is applied to the process of imparting to the surfaces of figures of wood, plaster of Paris, &c., a metallic appearance. This is done by first giving them a coat of oil or size varnish, and when this is nearly dry, applying with a dabber of cotton or a camel-hair pencil, any of the metallic bronze powders; or the powder may be placed in a little bag of muslin, and dusted over the surface, and afterwards finished off with a wad of linen. The surface must be afterwards varnished.

Paper is bronzed by mixing the powders up with a little gum and water, and afterwards burnishing.

Iron castings may be bronzed by thorough cleaning, and subsequent immersion in a solution of sulphate of copper, when they acquire a coat of the latter metal. They must be then washed in water.

BROOM ASHES. *Prep.* Burn broom stalks and collect the ashes. Sometimes used as a diuretic in dropsy.

BROOM COFFEE. Broom seeds, roasted

with a little butter and then ground. *Use.* As a substitute for coffee.

BROOM, SALT OF. Obtained by dissolving broom ashes in water, filtering and evaporating. *Remarks.* Antacid, consists principally of carbonate of potassa. Sometimes used in dropsy.

BROTH, (IN COOKERY.) The liquor in which meat is boiled; it is distinguished from soup by its inferior strength and quantity of seasoning, &c. The general method of preparing broth is similar to that of soup, to which article the reader is referred.

BROWN DYE. The different shades of this dye vary from pale yellow and reddish brown, up to very dark brown, almost black, every shade of which, however, may be produced as the taste of the workman may dictate, by mixtures of reds and yellows with blues and blacks, or by simple dyes, which at once impart a brown,—as catechu, walnut rinds, or oxide of manganese.

I. (*For Wool.*) *a.* Boil the cloth in a mordant of alum, and common salt dissolved in water, then dye it in a bath of logwood, to which a little green copperas has been added. The proportion of alum should be 2 oz., and of salt 1 oz., to every pound of cloth.

β. Boil the goods in a mordant of alum and sulphate of iron, then wince them through a bath of madder. *Remarks.* The tint depends on the relative proportions of the alum and copperas; the more of the latter, the darker will be the dye. The joint weight of the two should not exceed ⅛ of the weight of the wool. The best proportions are 2 parts of alum and 3 of copperas.

γ. Give the wool a mordant of alum and tartar, then pass it through a madder bath, which will dye it red. It must now be run through a black bath of galls and sumach, or logwood, to which a little acetate or sulphate of iron has been added.

δ. Proceed to mordant the cloth as last, and dye in a madder bath, then remove it and add a little acetate or sulphate of iron, and again pass it through the bath, until the required tint is produced.

ε. Give the cloth a light blue ground with indigo, then give it a mordant with alum, wash in water, and run it through a bath of madder.

ζ. Give the cloth a mordant of alum and tartar, then pass it through a madder bath, and afterwards through a bath of weld or fustic, to which a little iron liquor has been previously added. In this way every shade from mordoré and cinnamon to dark chesnut may be dyed.

η. Boil 1 lb. of fustic chips for 2 hours, and pass the cloth through the bath for 1 hour, take it out and drain, then add 1½ oz. of green copperas, and ½ lb. of good madder, and pass the cloth again through the bath, until the proper tint is produced. This makes bronze browns, but by varying the proportion of the mordant, other shades may be produced.

II. (*For Silk.*) *a.* Give the silk a mordant as before described, then dye in a bath made by mixing the equal parts of decoction of logwood, fustic, and Brazil wood. The shade may be varied by mixing the decoctions in different proportions. *Brazil wood reddening, logwood darkening,* and *fustic yellowing,* the tint.

β. Dissolve 4 oz. of annotto and 1 lb. of pearl-ash in boiling water, and pass the silk through it for 2 hours, then take it out, squeeze it well and dry; next give it a mordant of alum, and pass it *first* through a bath of Brazil wood, and afterwards through a bath of logwood, to which a little green copperas has been added; wring it out and dry; afterwards rinse well.

III. (*For Cotton and Linen.*) *a.* Give the pieces a mixed mordant of acetate of alumina and acetate of iron, and then dye them in a bath of madder, or madder and fustic. When the acetate of alumina predominates, the dye has an amaranth tint. The iron darkens it.

β. First gall the goods, then turn them for a short time through a black bath, next give them a mordant of sulphate of copper, and pass them through a decoction of fustic, afterwards through a bath of madder, and again through the solution of sulphate of copper; drain, dry, and rinse well, then finish with a boil in soap and water. This gives a chesnut brown.

γ. First give a mordant of alum, then pass the goods through a madder bath, and next through a bath of fustic, to which a little green copperas has been added. This gives a cinnamon brown.

Remarks. Browns may be also dyed at once, by what are called substantive or direct dyes; thus—

I. *Decoction of oak bark* dyes wool a fast brown of various shades, according to the quantity employed. If the cloth be first passed through a mordant of alum, the color is brightened.

II. *Infusion or decoction of walnut peels* dyes wool and silk a brown, which, like the preceding, is brightened by alum. The older the liquor the better.

III. *Horse-chesnut peels* also give a brown. A mordant of muriate of tin turns it on the bronze, and sugar of lead the reddish brown.

IV. *Catechu, or terra japonica,* gives cotton a brown dye; blue vitriol turns it on the bronze, and green copperas darkens it, when applied as a mordant, and the stuff dyed in the bath boiling hot. Acetate of alumina as a mordant brightens it. The French color, called "carmelite," is given with 1 lb. of catechu, 4 oz. of verdigris, and 5 oz. of sal ammoniac.

V. *Sulphate or muriate of manganese,* dissolved in water with a little tartaric acid, gives the bronze tint called "solitaire." The stuff, after being passed through the solution, must be turned through a weak lye of potash, and afterwards through another of chloride of lime, to brighten and fix it.

VI. *Prussiate of copper* gives a bronze or yellowish-brown to silk. The piece well mordanted with blue vitriol, may be passed through a solution of *prussiate of potash.*

BROWN PIGMENTS. The principal and most useful of these are, umber and terra di sienna, both burnt and raw. Brown may also be made of almost any shade, by the admixture of blacks with reds and yellow, or with greens, in different proportions.

BROWNING, (IN COOKERY.) A fluid preparation used to color and flavor gravies, soups, &c.

Prep. I. Melt 4 oz. of sugar in a frying-pan, or other convenient vessel, with water, add 1 oz. of butter, and continue the heat until the whole is turned quite brown; then pour in 1 pint of port

wine, stirring well all the time, and remove the pan from the fire. When the whole of the roasted sugar is dissolved, pour it into a bottle, and add ½ oz. each of bruised pimento and black pepper; 6 shalots cut small; a little mace and finely-grated lemon-peel; and a quarter of a pint of mushroom catsup. Digest for a week, occasionally shaking; then strain through a piece of muslin, and preserve for use.

II. Instead of port wine use water, and add a glass of spirits.

III. Sugar coloring 1 pint; salt ¼ lb.; mushroom catsup ½ pint; add spice.

IV. Lump sugar (powdered) 2½ lbs.; salad oil ½ lb.; heat in an iron vessel until quite brown, then add port wine 1 quart; Cape wine 3 quarts; shalots 6 oz.; mixed spice 4 oz.; black pepper 8 oz.; mace 1 oz.; salt ¾ lbs.; lemon juice ½ pint; catsup 1 quart.

V. Good spirit, or sugar coloring, and mushroom catsup, of each 1 gal.; Jamaica pepper, black pepper, and shalots, of each 4 oz.; cloves, cassia, and mace, bruised, of each ¾ oz.; boil in a covered vessel for 5 minutes, then digest for 14 days, and strain.

BROWNING FOR GUN BARRELS. *Prep.* I. Mix 1 oz. each of aquafortis and sweet spirits of nitre; 4 oz. of powdered blue vitriol; 2 oz. of tincture of iron, and water, 1½ pint; agitate until dissolved. *Use.* Rub this on the barrel, previously well polished, and afterwards cleaned off with whiting to remove the oil. Let it remain till the next day, then rub it off with a stiff brush. The liquid may be again applied until a proper color is produced. When this is the case, wash in pearlash water, and afterwards in clean water, and then polish, either with the burnisher or with beeswax; or apply a coat of shellac varnish. (See below.)

II. Blue vitriol and sweet spirits of nitre, of each, 1 oz.; water 1 pint; dissolve as last.

III. Mix equal parts of butter of antimony and sweet oil, and apply the mixture to the iron previously warmed.

Remarks. The varnish used for gun barrels, after they are bronzed, is made by dissolving 1 oz. of shellac and one or two drachms of dragon's blood, in a quart of alcohol; and filtering the solution through blotting paper into a bottle, which must be kept closely corked.

BRUCINE. *Syn.* BRUCIA. BRUCINA. VOMICINA. A vegetable alkali, discovered by Pelletier and Caventou, in the bark of the Brucia antidysenterica, and afterwards combined with strychnia in nux vomica.

Prep. Digest ether on the powdered bark of brucia antidysenterica, to separate a fatty matter; strain, add alcohol at 36° Baume; digest, filter, evaporate to dryness; dissolve the mass in water, add liquid subacetate of lead; filter, pass sulphureted hydrogen gas through the clear liquor; filter again, and add calcined magnesia; filter again, wash the sediment very slightly with cold water, dry, digest in alcohol, filter, and distil off the spirit. To purify the brucine, add a solution of oxalic acid, crystallize, add a mixture of alcohol at 40° Baume, and ether at 60°, to extract the coloring matter, then dissolve the oxalate of brucine in water, add calcined magnesia, filter; digest the sediment in alcohol, filter, and let the spirit evaporate by exposure to the air.

Prop., Use, &c. The crystals thus obtained are soluble in 850 parts of cold and 500 parts of boiling water. When added to the dilute acids until they are neutralized, brucia forms crystallizable salts, easily obtained by evaporation. Of these, the sulphate and bisulphate, the muriate, phosphate, nitrate and binitrate, acetate, oxalate, and some others have been examined. Most of these, especially the first three or four, are very soluble in water. Its physiological effects are similar to strychnia, but it is said to possess only $\frac{1}{12}$ of the strength of that alkali. According to Dr. Fuss and Professor Erdeman, it is not a distinct alkaloid, but a compound of strychnia and resin. *Dose.* ½ gr. to 2 or 3 grs. daily, in the form of pills or solution. It is given in similar cases to those for which strychnia is prescribed: viz. paralysis, impotence, and other affections of the nervous system. It is a violent poison. Its antidotes are the same as those for strychnia. *Tests.* Nitric acid gives it a fine red color, which is removed by sulphureted hydrogen and sulphurous acid. Iodic acid, chloric acid, and chlorine, also turn it red.

BRUCINE, PILLS OF. *Prep.* Brucia 2 grains; conserves of roses and liquorice powder, of each, 1 scruple; mix and divide into 16 pills. *Dose.* 1 to 6 daily, at first, gradually increasing the dose.

BRUISES. *Treat.* These may be rubbed with a little opodeldoc or soap liniment; or if the inflammation be considerable, they may be washed with a little weak goulard water, or leeches may be applied to the part.

BRYONIN. A peculiar bitter principle, extracted from the white bryony or mandrake root. It is obtained from the expressed juice by filtration, evaporation to dryness, and re-solution in alcohol. It is a drastic purgative and poisonous. It forms a yellowish white mass.

BUBBLE AND SQUEAK, (IN COOKERY.) *Prep.* Cut slices from a cold round of beef; let them be fried quickly until brown, and put them into a dish to keep hot. Clean the pan from the fat; put into it greens and carrots previously boiled and chopped small; add a little butter, pepper, and salt; make them very hot, and put them round the beef with a little gravy. Cold pork boiled is a better material for bubble and squeak than beef, which is always hard; in either case the slices should be very thin and lightly fried.

BUGS. Various means have been proposed to drive away these noctural marauders and enemies of "*tired nature's sweet restorer, balmy sleep.*" Among the most certain of these is cleanliness. The furniture brokers put articles infested with this insect population into a room with doors and windows fitting quite close, when they subject them to the fumes of burning sulphur or chlorine In the small way, poisonous mixtures are frequently resorted to, with which the articles are washed. The following form is that usually employed:—

Corrosive sublimate and muriatic acid, of each, 1 oz.; water 4 oz. Dissolve, then add turpentine and decoction of tobacco, of each, ½ of a pint. Mix.

⁂ For the decoction of tobacco, boil 2 oz. of

tobacco in a pint of water. This mixture must be applied with a paint brush. *Caution.* This wash is a "*deadly poison!*"

The following extract may be of assistance to persons interested in the matter:—"These pests exist only in dirty houses. A careful housewife or servant will soon completely destroy them. The surest method of destruction is to catch them individually when they attack the person in bed. When their bite is felt, instantly rise and light a candle and capture them. This may be troublesome, but if there be not a great number, a few nights will finish them. When there is a large number, and they have gained a lodgment in the timbers, take the bed in pieces, and fill in all the apertures and joints with a mixture of soft soap and Scotch snuff. A piece of wicker-work, called a bug-trap, placed at the head of the bed, forms a receptacle for them, and then they may be daily caught till no more are left. Fumigations are very dangerous, and rarely effectual, therefore attempt no such project. Oil-painting a wall is a sure means of excluding and destroying them." (Chamber's Information for the People, No. 91, p. 653.)

BUNION. *Cause and Treat.* The *bunion*, or swelling on the ball of the great toe, is produced by the same cause as the corn—pressure and irritation by friction. The treatment recommended for corns will succeed in cases of bunions; but in consequence of the greater extension of the disease, the cure of course is more tedious. When a bunion is commencing, it may be effectually stopped by poulticing, and then opening with a lancet; but this requires caution, and should be performed with care.

BUNS. *Prep.* I. (*Cross Buns.*) To flour 2½ lbs., add sifted sugar ½ lb., and a little coriander seed, cassia, and mace, powdered fine, then make a paste with butter ½ lb., dissolved in hot milk ½ a pint, work in 3 tablespoonfuls of yeast and a little salt; set it before the fire for an hour to rise, then make it into buns, and again set them before the fire on a tin for half an hour; lastly, brush them over with warm milk, and bake them to a nice brown in a moderate oven.

II. (*Madeira.*) Butter 8 oz.; 2 eggs; flour 1 lb.; powdered sugar 6 oz.; half a nutmeg, grated; powdered ginger and caraway seeds, each 1 teaspoonful; work well together, then add sherry wine 1 glassful, and as much milk as required. Bake in tins in a quick oven.

III. (*Plain.*) *a.* Flour 2 lbs.; butter ¼ lb.; sugar 6 oz.; a little salt, powdered caraway and ginger; make a paste with yeast, 4 spoonfuls, and warm milk a sufficient quantity, then proceed as in No. I.

b. To the last add currants, well washed, ½ lb.

IV. (*Rich.*) Dried and warm flour 3 lbs.; powdered sugar 1 lb.; butter 2½ lbs., melted and beat with rose water 4 oz.; form into a light paste, with ¾ of a pint of yeast, and place it for an hour to rise, then add a little candied lemon and orange peel, and 1 lb. of currants, and make the whole into buns; set them before the fire for 40 minutes, then wash them over with milk, and put a little grated peel and a few caraway comfits on the top of each.

BURGLARIES, TO PREVENT. "In addition to the usual precautions of locks and bolts, alarum bells and firearms, three things have been found efficacious in preserving houses from nightly depredators. 1st. A *light* in the upper part of the house. 2d. A *small dog*, in a room on the ground floor, which offers the means of its running into a place of safety from its enemies: not to be fed too high, and allowed to sleep by day. 3d. Some *ashes* fresh from the fireplace spread before the door, underneath the window or other place. Thus the thieves' shoes will creak, the dog will be roused and bark, and the fear of detection by the approach of the light, will deter rogues of common feeling. At least, should they enter, the dog cannot be readily come at to be slain; and the scuffle occasioned by effecting this necessary prelude to robbery, will, in almost all cases, promote interruption from within or without."

BURNS AND SCALDS. These are too well known to require description.

Treat. When the injury is merely superficial, a little creosote may be applied to the part, and if it be a scald, the vesicle may be first pierced with a needle, and the aqueous fluid gently squeezed out. When creosote is not to be procured, a liniment formed with equal parts of soft soap, basilicon ointment, oil of turpentine and water may be used instead. When the part is very hot and painful, a poultice may be applied, on the surface of which a few drops of creosote, or the liniment, should be spread with a knife. This treatment will generally allay the pain, after which a dressing of any simple ointment may be adopted. In many severe flesh burns which I have had the misfortune to receive, I poured creosote *plentifully* over the part, which produced scarcely any smarting or pain, as is frequently asserted, whilst it removed the burning sensation that previously existed, and the charred surface assumed a dry scabby appearance, which, by dressing with simple ointment, soon came off and left the part beneath both sound and healthy. If a poultice be applied, it is best to keep it on until the next day, when in general a little spermaceti ointment spread on a bit of soft linen may be used instead. Plunging the part into cold water *immediately* on the receipt of an injury of this kind will frequently prevent any further remedy being necessary. In all cases of burns and scalds, it is necessary to observe that if fever should ensue, laxative medicines, as castor oil and epsom salts, should be administered.

BURNING LENS, CHEAP AND SIMPLE. Take two circular discs of plate glass, of the requisite dimensions, and place one at each end of a shallow tube; an inch long will be quite sufficient for any size; they are kept in their position very firmly by means of screw clamps, in an analogous manner to the two lenses for showing Newton's concentric colored rings. To the tube is fitted a short tube with a stop-cock attached; to the end of this tube a condensing syringe is fixed, and the cavity between the glasses filled with turpentine, varnish, bleached oil, or any other suitable substance of a high refractive power. When the glasses have attained the requisite degree of curvature, the stopcock may be shut, the syringe screwed off, and the fluid lens (for such in reality it is) mounted for use. (Chemist, iii. 50.)

BUTTER. *Qual., &c.* This article is perhaps

employed for this purpose with advantage. It is only necessary to mix the flour up with the jelly, instead of mere water, to add yeast and salt, and to bake in the common way. Dr. Percival has recommended the addition of salep for this purpose. 1 oz. of salep dissolved in 1 quart of water; 2 lbs. of flour; 80 grains of salt, and 2 oz. of yeast, gave 3 lbs. 2 oz. of good bread; but the same weight of materials, without the salep, gave only 2¾ lbs. If too much salep be added, however, it will give its flavor to the bread.

BREAD, WHITING'S, (PATENT.) This is made by dividing the dough into two portions; to the one a little carbonate of soda is added, to the other, a little dilute muriatic acid; they are both well kneaded separately, then mixed together, formed into loaves, and baked immediately. No yeast is used.

BREATH, FŒTID. Scarcely any thing is more disagreeable or disgusting than a stinking breath. Various means have been proposed to remove this annoyance, depending principally on the administration of aromatics, which by their odor might smother it for a time; but these require continual repetition, and are liable to interfere with the functions of digestion. The real cause of a stinking breath is either a diseased stomach or carious teeth; when the former is the case aperients should be administered; and if these do not succeed, an emetic may be given, followed by a dose of salts, or castor oil occasionally. When rotten teeth are the cause, they should be removed; or, if this be impossible, they should be kept clean. Dirty teeth often cause the breath to smell. The use of the tooth-brush should be a daily habit. Occasionally rinsing out the mouth with a little clean water, to which a few drops of a solution of chloride of lime, or chloride of soda, has been added, is an effective method. The following lozenges have also been recommended:—

Gum catechu 2 oz.; white sugar 4 oz.; orris powder 1 oz.; make them into a paste with mucilage, and add a drop or two of neroli. One or two may be sucked at pleasure.

BREAKFAST POWDER. *Syn.* RYE COFFEE. DILLENIUS'S DITTO. HUNT'S ECONOMICAL BREAKFAST POWDER. Rye roasted along with a little fat. *Use.* As a substitute for foreign coffee, of which it is one of the cheapest and best.

BREE'S ANTI-ASTHMATIC PLASTER. *Prep.* Simple diachylon 1 oz.; powdered camphor and powdered opium, of each ¼ oz.; sweet oil ½ a teaspoonful. *Proc.* Melt the plaster with the oil, then remove the vessel from the fire, and stir in the powders; spread it on leather before it gets cold. *Remark.* It is better made with only half the above quantity of opium.

BREWING. The art of making beer.

General notice. Before entering on a description of the process of brewing, it will be necessary to notice the apparatus and materials required for its conduct.

The apparatus consists of,

1. *A copper or boiler* capable of holding fully two-thirds of the quantity proposed to be brewed; with a gauge-stick to determine the number of gallons of fluid at any given depth therein. A copper holding about 140 gallons is a convenient size for brewing a quarter of malt.

2. *A mash-tub*, or *tun*, capable of containing rather more than the copper.

3. *One or more tuns, or vessels*, to ferment the beer in.

4. *Three or four shallow coolers* to reduce the wort as rapidly as possible to a proper temperature for fermenting.

5. *One or two copper or wooden bowls*, for bailing, &c.

6. *A thermometer* with a scale reaching from zero to above the boiling point of water.

7. *A suitable number of casks* (clean) to contain the beer.

8. *One or more large funnels, or tunners.*

9. *Two or more clean pails.*

10. *A hand-pump* of a size proportionate to the brewing.

These articles will vary in value from £10 upwards, to many hundreds, according to the extent of the brewing; but the whole of them, necessary for a private family, may be bought for less than the former amount. By proper care they will last for 30 or 40 years, and still be in a useful state. The place where these vessels are kept, and the operations carried on, is called the "*Brewhouse.*"

The materials necessary to brew beer are, *good malt, hops*, and *water*, and a little *yeast*.

The *malt* is bruised or crushed in a mill before brewing, that it may be acted on the more readily by the water. It should not be ground too small, as it would then make the wort thick; the crushed malt may advantageously lie for a few days in a cool situation, by which it will attract a considerable quantity of moisture from the air, and consequently its soluble portion will be the more easily dissolved out by the water used in mashing. Pale malt may be used coarser than amber or brown malt. A bushel of malt should make a bushel and a quarter when ground, and a quarter should yield between 9½ and 10 bushels, the quantity slightly varying according to the degree of bruising it has undergone. On the large scale, malt is ground in crushing mills, furnished with iron rollers; and on a small scale, by wooden rollers or small mills worked by hand. For private brewing, the malt is generally bought ready ground, for convenience sake. (See MALT.)

The hops should be those of the previous season, and for general purposes grown in Kent; but for the finer sorts of malt liquor, East Kent hops should be used; and where it is intended to be kept for some long time, those known by the names of *Country's*, *Alton's*, or *Farnham Hops* must be employed. The quantity of hops required to a given measure of malt varies from 2 lbs. to 8 lbs. of the former, to 1 quarter of the latter, according to the nature of the brewing. For good strong beer, 4 lbs. or 4½ lbs. is usually sufficient, but when the liquor is very strong, and it is intended to be highly aromatic, and to be kept for a long period, 1 lb. of hops may be used to every bushel of malt, or 8 lbs. to the quarter. Mild porter has about 3 lbs. to the quarter, and weak common beer has frequently only about ¼ lb. of hops to the bushel of malt. A portion of hops is also frequently added to the finer sort of beer, after it is casked, as we shall presently explain.

The water should be *soft* and *clear*, the *yeast sweet* and *good*, and all the vessels and casks both

sweet and *clean*. If this be not the case, with the latter especially, the best brewing in the world will be useless.

PROCESS OF BREWING. This may be divided into

I. *The mashing*. This operation consists in placing the ground or bruised malt in a large tub or "*tun*," known by the name of the "*mash-tun*," macerating it for some time in hot water, and lastly drawing off the wort from a hole in the bottom, over which a bunch of straw, or a strainer, or false bottom, is placed, to prevent the malt passing out along with the liquor. During the process of mashing, a peculiar principle, called by chemists *diastase*, reacts upon the starch also contained in the malt, and converts it first into a species of gum, called by the French chemists "*dextrine*," and then into a species of sugar resembling that produced by the action of sulphuric acid. The greater the quantity of starch converted into sugar in this way, the stronger and finer will be the wort. It therefore becomes a desideratum with the brewer to mash at a temperature that will most fully promote this object. It has been found that the best temperature for this purpose varies from 157° to 160°, but when more than one liquor is used, the first should be something lower than the former, the next may be between the two, and the third may slightly exceed the latter, or be about 165° or 170°. The action of the first mash is merely to extract the sugar contained in the malt already formed; that of the second to convert the starch into sugar by the action of the diastase; the third to fully complete this object, as well as to carry away the remaining portions of extract.

The mashing is usually performed by filling the copper with water, and as soon as it acquires the temperature of 145° in summer, or 167° in winter, 45 gallons are run off into the mash-tun, and 1 quarter of crushed malt gradually thrown in and well mixed by laborious working, until it becomes thoroughly incorporated and no lumps remain; the agitation is then continued for 30 or 40 minutes, when 36 gallons of water from the boiler, at a temperature of 200°, are added, and the whole again well agitated until thoroughly mixed. The mash-tun is now closely covered up, and allowed to stand for an hour or an hour and a half. At the end of this time the tap is set, and the wort is drawn off into the "underback," and generally amounts to about 50 to 52 gallons: 60 gallons of water, at a temperature of 200°, are next added to the mash-tun, previously drained well, and after being well worked, the whole is covered up as before. This mash is allowed to remain for an hour, when it is drawn off, and the malt again drained ready for the third mash. This time only 35 gallons of water are added at 200°, and allowed to stand for ½ an hour, when it is run off in the same manner as before, and the malt allowed to drain. The worts are now ready for boiling.

In some cases only the first and second mash is used for strong beer, and the third kept for table, or as water to mash a fresh quantity of malt with. In Scotland (see SCOTCH ALE) the brewer only mashes *once*, and afterwards washes his malt by frequent showers or "sparges" of water, by which he gets a wort of greater strength in proportion to its quantity. In operating as above, the average or mean temperature of the first mash is 145°, of the second 170°, and of the third 180°. In winter the mean temperature may be reckoned as 6 or 7° lower. A quarter of malt in this way will produce a wort having a specific gravity by the saccharometer of 1·234, or equal to 84 lbs. of extract. (See SACCHAROMETER.)

It is calculated that 32 gallons of the water employed in the mashing remain in the grains after the wort is drawn off.

II. *Boiling*. The wort is next transferred to the copper, and heated to the boiling point as soon as possible. In large breweries where several coppers are employed, the first mash is no sooner run into the underback, than it is transferred to the wort copper, and immediately boiled, and the successive mashings added as soon as drawn off; but in private houses, where there is only one copper, the boiling cannot be commenced until the water for the last mashing is removed. In some cases the worts are brewed separately, thus producing 2 or 3 qualities of beer, viz. *strong ale or stout, beer, and table beer*. No sooner has the boiling commenced than the hops may be added, and the boiling continued for 2 or 3 hours or more. In some breweries the beer is boiled for several hours, and in Belgium it is said that this is even continued for 10 or 12 hours, but too much boiling drives off the flavor of the hops. In general, two hours good boiling will be found sufficient. In small brewings the first wort should be sharply boiled for 1 hour, and the second for 2 hours. But if intended for beer of long keeping, the time should be extended half an hour. The hops should be strained from each preceding wort, and returned into the copper with the succeeding one. Between the boilings the fire should be damped with wet cinders, and the copper door set open.

For small-beer only half an hour is necessary for the first wort, 1 hour for the second, and 2 hours for the third.

It is reckoned that $\frac{1}{6}$ to $\frac{1}{15}$ part of the wort is dissipated in steam during the process of boiling, but this must of course depend altogether on the evaporative power of the boiler and the length of time the boiling is continued.

III. *Cooling*. The boiling being finished, the wort is run off from the copper into the hopback, which is furnished with a strainer to keep back the hops. It is then pumped into large square shallow vessels called "*coolers*," where it is exposed to a good current of air to cool it down to a proper fermenting temperature as quickly as possible. This is of the utmost importance for the success of the brewing. The wort should be laid so shallow as to cool within 6 or 7 hours to the temperature of about 60°. In warm weather, the depth should not exceed 3 or 4 inches; but in cold weather it may be 5 or 6 inches. As soon as the heat has fallen to about 60°, it should be instantly tunned and yeasted.

It is reckoned that by the joint evaporation from the boilers and coolers, there is a loss of about 40 gallons per quarter.

In private families a good way is to bring the wort from the copper in pails, and to pour it into a basket or a hamper, set over the coolers, by which means the hops will be retained, and the beer run through clear.

BOYLE'S FUMING LIQUOR. Hydrosulphuret of ammonia is usually employed and sold for this article, but the liquor prepared by Boyle's process contains an excess of sulphur. (Gay Lussac.) The properties of both are however the same.

Prep. Mix 4 parts of fresh slaked lime; 2 of sal ammoniac, and 1 of sulphur, then submit the mixture to distillation.

BRA GRAS. Tar, black rosin, and the dregs of strained rosin, melted together.

BRAIN CAKES. *Prep.* Clean, wash, blanch, and soak the brains, then beat them up with a little white pepper and salt, a sage-leaf or two, scalded and finely chopped, and the yelk of an egg; make them into small cakes or fritters, and fry them.

BRAN. The husk of wheat which immediately covers the grain, and which is left in the bolting machine. *Use.* It is largely employed by the calico printers, when diffused through hot water, to remove the coloring matter from those parts of their goods which are not mordanted. A handful mixed with a pail of warm water, forms an excellent emollient foot-bath. Infused in water, (*bran tea,*) and sweetened, it forms a popular demulcent, much used in coughs and hoarseness, and, taken in quantity, proves gently laxative. It also forms an excellent manure, and, from containing the ammoniaco-magnesian phosphate, is especially adapted for potatoes. It is frequently mixed with flour and made into bread, by the poorer orders.

BRANDY. *Syn.* Eau de Vie. Aqua Vitæ. Spiritus Gallicus. Brandy-wine. The spirituous liquor obtained by the distillation of wine. When first distilled it is colorless, and only acquires a yellowish tint from the wood of the casks, in which state it is known and sold as pale or white brandy. The deep color that it usually possesses, is imparted to it by adding a little spirit coloring, (burnt sugar or caramel,) and occasionally a little red sanders wood as well, and is intended to imitate the appearance acquired by brandy from great age, when kept in wood. The natural color, however, which the spirit receives from the cask, no matter how long it may have been in it, never exceeds an amber tint, about the common color of pale Jamaica rum; but the public taste has been gradually vitiated in this respect, until only a spirit of a lively and full "*brandy color*" (unless for a pale brandy) will sell.

The brandies most esteemed in England are imported from France, and are those of Cognac and Armagnac, the preference being generally given to the former. The brandies of Rochelle and Bordeaux may be reckoned next in quality, while those obtained from Portugal, Spain, and Italy are very inferior.

The constituents of brandy are alcohol and water, and small quantities of volatile oil, acetic acid, acetic ether, œnanthic ether, coloring matter, and tannin. It is from the presence of the last six of these substances that the spirit derives its distinguishing smell and flavor. The quantity of alcohol present in brandy varies from 48 to 55 per cent. When first imported, it is generally 1 or 2 overproof, but by age its strength is lessened, and by the time it is usually taken from the bond store for sale, seldom exceeds 3 or 4 underproof. From considerable personal acquaintance with the cognac trade, I feel confidence in asserting, that brandies of the best quality seldom exceed proof, and are generally below it, and that it is a common practice in France to add spirit of wine and coloring to raise the strength to any given point desired by the English purchaser, and to charge the same in the invoice; or where the purchaser is not *well acquainted with the subject*, and desires a strong spirit at a low rate, to sell him brandy so mixed as genuine. The very finest brandies average from 5 to 10 u. p., and never exceed about 2 u. p.; they then contain more than ½ their weight of water, and from their boiling point being higher, they come over more highly charged with essential oil, and other volatile and fragrant principles of the grape, and thus possess in a greater degree that peculiar aroma and flavor for which they are so much esteemed. French brandy or wine, distilled at a low temperature in a water bath, yields a very pure and scarcely flavored spirit.

The quality of the brandy imported from France varies considerably from that which is drunk on the continent, principally from its being *prepared*, or, as it is technically termed, "*made up,*" for the London market, which means lowering it by the addition of spirit, coloring, &c. above described. The common strength at which foreign brandy is sold in England is about 11 or 12 u. p., and below 17 u. p. it becomes seizable by the excise. The strength at which it is sold and permitted in trade, is generally 10 u. p., to which it is reduced by adding water, and never less than 12 u. p., unless it be specially agreed upon. In large quantities and from bond, of course the strength depends much upon the age and quality of the spirit. A fine old brandy being, perhaps, 8 or 10 *u. p.*, while one of the last year's vintage of a commoner quality may be as strong as 2 or 1 *u. p.* But these distinctions are familiar to every experienced brandy dealer.

In France there are several varieties of this spirit distilled, which are known by names descriptive both of their quality and source. The "*eau de vie supérieure,*" or *cognac brandy*, is generally obtained from pale white wines, by careful distillation, and is remarkable for its superior flavor. When kept in glass or stone bottles, it is called white cognac brandy, and the same term is also generally applied when it has been kept in casks, but has not been artificially colored; in the latter case, however, it generally acquires a pale amber tint.

The "*eau de vie ordinaire,*" or *common brandy*, is distilled from high-colored white or red wines, and has generally a sp. gr. of 0·948, and varies from 22 to 27 u. p.

The "*eau de vie de marc*" is obtained from the lees of vinegar and other wines, the marc or cake of grapes from which the juice has been pressed, and the commonest red wines, fermented and distilled together by a quick fire, to drive over as much essential oil and flavoring as possible.

The "*eau de vie seconde*" is the weak spirit that passes over after the stronger spirit has been drawn off, and the receiver changed. *It is used* for common drinking, or mixed with other brandy.

The "*eau de vie à preuve d'Hollande*" is brandy about 19° Baume, or sp. gr. ·9420, the common strength at which it is retailed in France, and will stand the "*proof*" or "*bead*"

The "*eau de vie à preuve d'huile*" is the strongest brandy usually drunk; it is about 23° Baume, or sp. gr. ·918; pure olive oil will just sink in it; hence the above term.

The "*eau de vie fort*" is usually prepared by the redistillation of common brandy, keeping the first portion separate. It answers to our spirit of wine. It is made of 12 different strengths, distinguished by names, exhibiting the quantity of water required to reduce the sample to the "*preuve d'Hollande.*" The weakest is called cinq-six, or $\frac{5}{6}$, and the strongest trois-neuf, or $\frac{3}{9}$, the difference between the numerator and the denominator being the quantity of water the 3 parts of the former will take to reduce it to the "*preuve,*" when it would make 9 parts. Its sp. gr. is about ·839.

The *esprit de vin* is brandy or spirit rectified to 0·890 and upwards.

The general method of distilling brandy in France differs in no important particular from that practised in England, for grain or molasses spirit. Neither are the French workmen more skilful nor more cleanly in their operations than the English. It is the materials alone that, in this case, conduce to the superiority of the product. The quality of the brandy varies with that of the wine from which it has been distilled. Every soil, every climate, every kind of grape, produces a wine possessing some peculiarity confined to itself, and this wine on distillation produces a spirit possessing like distinctions. A large quantity of brandy is prepared in France soon after the vintage, as the juice of the poorer grapes that is unfit for wine is fermented and at once distilled. It is a general rule, in France, to distil only such wines as are unsaleable, as the profits on the wine, sold as such, are much greater than when it is converted into brandy.

The Strength of Brandy may be ascertained in the same way as alcohol, for which purpose Sike's hydrometer is used in England. In France, from the value of spirit being less, it is frequently tested by simpler methods, though great accuracy obtains, in this particular, where necessary.

Pur. Very little perfectly pure French brandy is obtained by the small consumer in England, as it is not only generally lowered a little by the wholesale dealer, but undergoes a like process at the hands of the retailer. The safest method is either to procure it direct from the bond store, without its even entering a private cellar, or to buy of some known respectable party, and to pay a price that will offer no inducement to dishonesty. If this be not done, by all means buy British brandy, which is now made of excellent quality by many of the leading houses, as *Betts, Bretts, Booth,* and *Grimble.* From the two former a single sealed bottle may be procured at the same price as by the gallon.

The importation of foreign brandy for home consumption amounts to about 1,400,000 gallons a year.

BRANDY, (REDUCED.) I. To 20 gallons of Cognac brandy add 5 gallons of the best British brandy.

II. To 72 gallons of full-flavored French brandy, add 10 gallons of spirit of wine, (58 *o. p.,*) 8 gallons of water, and 1 pint of good coloring. Rummage well up and let it stand until the next day.

Remarks. The above reduction is generally adopted in trade, and is known by the name of "*improving.*" But such is the poverty of the palate of the English brandy drinker, that the adulteration is often not suspected, even when it is carried to double the extent of the above, which is generally exceeded in the hands of the retailer. So long, however, as the foreign spirit constitutes about half of the mixture, and was at first of decent quality and age, the infatuated Englishman smacks his lips, and cunningly holding up his glass between the light and his eye, exclaims, "*Ah! this is a drop of the real.*"

BRANDY, (BRITISH.) *Syn.* British Cognac. Imitation Cognac, &c. From the heavy duty levied on French brandy imported into England for home consumption, it has become a desideratum with the distiller (rectifier) to produce an English spirit of a similar description. For some time the attempt proved quite unsuccessful, but of late years much capital and talent have been embarked in the pursuit, and the result has proved very satisfactory. An article of British manufacture may now be purchased, at a very reasonable rate, of really respectable quality, and possessing much of the flavor and aroma of foreign brandy, while, as a beverage, it is equally wholesome. Much of the British brandy, however, that is commonly met with, is of such a wretched quality as to be quite undeserving of the name, which is evidence of the fact, that much skill and experience is required to ensure success in its manufacture. For a long time this liquor was distilled from spoilt wine and dregs of wine, both British and foreign, mixed with beer bottoms and similar articles; and when, instead of these, corn, malt, and molasses spirit were employed, it was considered as an unpardonable and wicked misuse of those articles. Modern experience has proved, however, that perfectly pure and tasteless malt spirit is the best article to form into an imitation brandy.

The following formulæ, by skilful management, will produce very good brandy, but it must be recollected that much depends on the quality of the materials employed, as well as on the operator. As the strength and quality of the ingredients, and the methods of manipulation vary, so will the result; much must therefore be left to the judgment and discretion of the artist. It offers a profitable pursuit to the ingenious and industrious chemist and rectifier.

Prep. I. Take 12 gallons of the finest flavorless malt spirit at proof, (or if of a different strength a proportionate quantity;) add thereto 5 gallons of water, $\frac{3}{4}$ lb. of the best crude red tartar or winestone, previously dissolved in 1 gallon of boiling water; $\frac{1}{4}$ pint of acetic ether; 2 quarts of good French wine vinegar; 7 lbs. of bruised French plums, and 1 or 2 gallons of wine bottoms or flavor stuff from Cognac, mix them in a fresh-emptied sherry cask, and let them stand together for 14 days, frequently rummaging up the liquor with a stick; next draw over 15 gallons of the mixture from a still furnished with an agitator. Put the rectified spirit into a clean, fresh-emptied Cognac brandy cask, and add thereto $\frac{3}{4}$ pint of tincture of catechu, 1 lb. of fresh and clean oak shavings, and about a pint of good spirit coloring. Bung close, and agitate occasionally for a few days. *Remarks.* Age improves the above article, and renders it

"Metallic spoons are used when the substance to be examined is intended to be exposed to the action of heat only, and might undergo some change by immediate contact with the charcoal. When the spoon is used, the flame of the blowpipe should be directed to that part of it which contains the substance under examination, and not be immediately applied to the substance itself. The handle of the spoon may be inserted into a piece of charcoal; and if a very intense heat is required, the bowl of the spoon may be adapted to a hole in the charcoal. Small portions may be taken up by platina forceps. Salts and volatile substances are to be heated in a glass tube closed at one end, and enlarged according to circumstances, so as to form a small matrass."

When the behavior of the substance has been observed in this way, it is melted with various fluxes, as microcosmic salt, borax, &c., and their action examined, both in the interior and exterior flame, by which means its composition may be generally ascertained, by reference to any work on mineralogy.

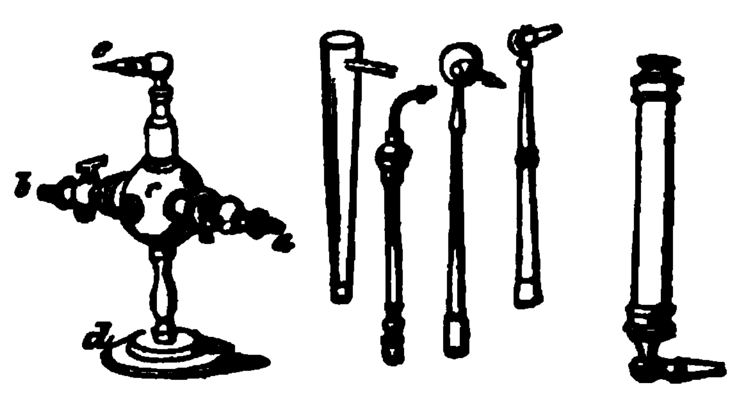
Beginners are usually unable to maintain a continual stream of air from the jet, which is, however, very simple to accomplish. The operation depends upon a little artifice in blowing through the pipe, which is in reality more difficult to describe than to acquire. "The effect intended to be produced is a continual stream of air for many minutes, if necessary, without ceasing. This is done by applying the tongue to the roof of the mouth, so as to interrupt the communication between the mouth and the passage of the nostrils; by which means the operator is at liberty to breathe through the nostrils, at the same time that by the muscles of the lips he forces a continual stream of air from the anterior part of the mouth through the blowpipe. When the mouth begins to be empty, it is replenished by the lungs in an instant, while the tongue is withdrawn from the roof of the mouth, and replaced again in the same manner as in pronouncing the monosyllable *tut*. In this way, the stream may be continued for a long time without any fatigue, if the flame be not urged too impetuously; and even in this case no other fatigue is felt than that of the muscles of the lips." (Ure.)

For producing extreme degrees of heat, the flame is blown with a jet of oxygen gas, and the instrument is then called an "*oxygen blowpipe;*" or a mixture of oxygen and hydrogen is burned, when it is called an "*oxy-hydrogen*" blowpipe. The heat produced by the last is so great that no substance can stand before it. The most refractory native compounds, as rock crystal, quartz, flint, chalk, plumbago, &c., are immediately fused. Gold is volatilized, and iron is rapidly consumed the instant it is placed in the flame. To use this wonderful instrument with safety, and to prevent an explosion, a peculiarly constructed jet is required. The principal blowpipes in general use are figured in the accompanying engravings. The shape of the common blowpipe adopted by the experimentalist may depend upon the fancy of its employer.

This apparatus is also furnished with valves and springs.

Beside the following there are several other va-

1 2 3 4 5 6



1, Oxy-hydrogen blowpipe.
2, Black's do.
3, Bergman's do.
4, Pepy's do.
5, Wollaston's do.
6, Hemming's safety jet for the oxy-hydrogen ditto.

a, Pipe conveying oxygen gas.
b, Do. do. hydrogen gas.
c, Ball stuffed with fine wire gauze.
e, Jet, (internal diameter 1-80th of an inch.)

rieties of blowpipes, in which the air is expelled by the pressure of a column of water, (hence called "*hydrostatic blowpipes,*") or the flame blown with the vapor of boiling alcohol, ("*spirit blowpipe.*")

Use. The blowpipe is of most extensive application in qualitative analysis, especially of minerals, and its use cannot be too highly recommended to the young chemist.

For further information on this subject the reader is referred to Gahn on the Blowpipe; to Ure's Dictionary of Chemistry; to Campbell's Translation of Kobell's Instructions for the Discrimination of Minerals; and to the Chemist, iv. 462.

BLUBBER. This substance, which is so plentiful on some parts of the coast of England, forms a very rich manure for pasture and arable land, when used at the rate of 1 ton to every 20 or 30 loads of mould, together with a chaldron of lime per acre. It must be well turned over, and after lying 3 or 4 months the land will be in prime condition.

BLUE, CHARCOAL. *Prep.* Triturate carbonized vine stalks with an equal weight of potash, then put it into a crucible and place it over the fire, until the mixture ceases to swell, keeping it well stirred all the time; next allow it to cool, dissolve it in water, and saturate the excess of alkali with dilute sulphuric acid; the liquid becomes blue, and a dark precipitate falls down, which turns of a brilliant blue color when dried and heated.

BLUE, COBALT. *Prep.* I. Dissolve Zaffre 1 lb. in $\frac{3}{4}$ lb. of nitric acid, diluted with an equal weight of water, by digestion for some hours, evaporate nearly to dryness, then dissolve in warm water, filter and add a solution of phosphate of soda as long as any precipitate falls down; collect this on a filter and wash it with cold water, then mix it while still moist with 8 times its weight of freshly precipitate hydrate of alumina, also well washed and still moist. Stir them together until dry; lastly, expose the mixture to a cherry red heat in a crucible, after which cool the mass, and reduce it to a fine powder.

II. Precipitate a solution of nitrate of cobalt as above, and proceed as before.

III. Make a strong solution of neutral nitrate

of cobalt, and mix it with pure moist alumina, then dry it and proceed as before.

IV. Precipitate a solution of nitrate of cobalt with ammonia alum, collect the precipitate, wash, dry, and heat it to a cherry red as before.

Use. A beautiful blue pigment, very permanent.

BLUE, CHEMIC. *Syn.* SAXON BLUE. LIQUID BLUE. SULPHATE OF INDIGO. *Prep.* I. Indigo 1 lb.; oil of vitriol 8 lbs. *Proc.* Put the acid into an earthenware pan, placed in a tub of water to keep it cool, and add the indigo, previously reduced to fine powder, in small successive portions, carefully stirring to prevent it *heating*. When all the indigo has been added, cover up the vessel and let it stand for 4 hours, occasionally stirring it during the time; lastly, dilute it with an equal weight of water.

II. Indigo 1 oz.; oil of vitriol 4 oz.; dissolve as before; the next day add 1 oz. of dry potash; let it stand a day longer, then dilute it with 12 oz. of water.

Use. In dyeing greens and blues, either without preparation or with a mordant of alum and tartar.

BLUE, CHINA. *Syn.* ROYAL SMALTS. *Prep.* Grind together oxide of cobalt or zaffre, with an equal weight of potash, and 8 times its weight of feldspar. Then submit the mixture to fusion in a crucible. *Use.* To paint pottery, and as a pigment.

BLUE, IRON. *Prep.* Precipitate a filtered solution of protosulphate of iron, with another of phosphate of soda. Collect the powder, wash and dry it. *Use.* A lively sky-blue.

BLUE, MOLYBDENUM. *Prep.* Dissolve sulphuret of molybdenum in nitric acid, then add some tin filings and a little muriatic acid. After digestion for some time, pour off the clear and evaporate to dryness. Mix the powder thus obtained with moist hydrate of alumina, as in making cobalt blue, and heat it to nearly a dull red.

BLUE, MOUNTAIN. Carbonate of copper, mixed with earthy matter.

BLUE, SAXON. *Prep.* Dissolve 1 oz. of sulphate of iron and 8 oz. of alum in 1 gallon of water, then add simultaneously, separate solutions of prussiate of potash and common pearlash, until they cease to produce a precipitate; lastly, allow the liquid to deposite, decant the clear portion, wash the remainder well with water, and dry it. Or a solution of the sulphate of iron may be first made and precipitated with the prussiate of potash, and instantly mixed with the solution of alum and a solution of pearlash, added until it ceases to produce a precipitate.

BLUE, SUPERB LIQUID. *Prep.* Put into a small matrass or common vial 1 oz. of pure Prussian blue reduced to powder, and pour over it from 1½ oz. to 2 oz. of concentrated muriatic acid. The mixture produces an effervescence and the prussiate soon assumes the consistence of thin paste. Leave it in this state for 24 hours, then dilute it with 8 or 9 oz. of water, and preserve the color thus diluted in a bottle well stopped.

The intensity of this color may be lessened, if necessary, by new doses of water. If the whole of this mixture be poured into 1 quart of water, it will still exhibit a color sufficiently dark for washing prints.

BLUE, STONE. *Syn.* FIG BLUE. THUMB BLUE. KNOB BLUE. CROWN BLUE. MECKLENBURG BLUE. QUEEN'S BLUE. *Prep.* Mix finely powdered indigo with starch paste until a proper color be produced, then make it into small lumps. II. Instead of starch use whiting and a little weak size. *Use.* Employed by laundresses to give a faint blue tinge to linen.

BLUE DYE. *Proc.* First give the goods a mordant of alum, then rinse them well and boil them in a bath of logwood, to which a small quantity of blue vitriol has been added.

II. Boil in a bath of logwood, then add 1 oz. each of tartar and verdigris to every pound of logwood employed, and boil again.

III. Bilberries, elder-berries, mulberries, privet-berries, and several other vegetable blue substances, may be used to dye blue as above instead of logwood.

Remarks. By increasing the proportion of alum the color verges on purple, and by employing a little acetate of iron or green copperas, the darker shades are produced. Verdigris, blue vitriol, and alkalis turn it more on the blue, and a mordant of tin imparts a violet cast. None of these dyes, however skilfully managed, are so permanent as those produced with indigo and Prussian blue. (See INDIGO, PRUSSIAN BLUE, and DYEING.)

BOARDS, MARBLE, &c., TO TAKE OIL AND GREASE OUT OF. I. Make a paste with fuller's earth and hot water, cover the spots therewith, let it dry on, and the next day scour it off with soft or yellow soap.

II. Make a paste with soft soap, fuller's earth, and a little pearlash, and use it as above.

III. Make a paste of fresh slaked lime, water, and pearlash, and use it as above. *Remarks.* Observe not to touch the last mixture with the finger, as it is very caustic unless it be largely diluted with water.

BOERHAAVE'S RULES FOR PRESERVING HEALTH.

"Keep the feet warm;
The head cool; and
The body open."

These rules are very concise, and convey directions which, though valuable, are too often neglected.

BOILING POINT. The boiling point of water may be raised considerably above 212° Fahr. by the addition of saline matter. Thus, 60 parts of dry acetate of soda added to 40 of water raise the boiling point to 256° Fahr., and 30 parts of muriate of soda added to 70 of water raise it to 224 Fahr. As in practice, however, it proves inconvenient to employ a saturated solution for a bath, from the evaporation of the water continually inducing the salt to crystallize, it is usual to keep it considerably below that point. By means of such solutions the chemist is enabled to evaporate fluids and desiccate solids at any required temperature. The boiling point of baths containing different salts may be seen below.

TABLE of the Boiling Points of several Saline Solutions, abridged from the Table of Mr. T. GRIFFITHS. (Jour. Science, xviii. 89.)

Names of Salts.	Dry Salt in 100.	Boiling Point.
Acetate of soda, . . .	60	256° F.
Nitrate of soda, . . .	60	246
Rochelle salt, ...	90	240
Nitre, ...	74	238
Muriate of ammonia, .	50	236
Tartrate of potash, . .	68	234
Muriate of soda, . . .	30	224
Ditto, ...	20	218·75
Muriate of lime, . . .	40	216·5
Sulphate of magnesia, .	57·5	222
Supersulphate of potash,	?	222
Borax, ...	52·5	222
Phosphate of soda, . .	?	222
Carbonate of soda, . .	?	220
Muriate of baryta, . .	45	220
Alum, ...	52	220
Sulphate of potash, . .	17·5	215
Bitartrate of potash, .	9·5	214
Sulphate of soda, . .	31·5	213

Remarks. From 5 to 9 degrees are usually lost by passing through the vessel, depending on its thickness and materials. The boiling point of water in glass vessels, under common circumstances, varies from 212·54° to 215·6°, and in perfectly pure and smooth glass vessels, water may be heated to 221° F. without boiling. (M. F. Marcet.)

BOILS. *Treat.* When these appear, suppuration should be promoted by poultices of bread and linseed meal, to which a little fat or oil may be added, to prevent their getting hard. When poultices are inconvenient, exposure to the vapor of hot water, or the application of stimulating plasters, may be adopted instead. When sufficiently ripe, the matter should be evacuated, and the wound dressed with a little simple ointment spread on a piece of clean lint or linen. The diet may be full and liberal until the maturation of the tumor and the discharge of the matter, when it should be lessened, and the bowels opened by some saline purgatives, as salts or cream of tartar. When there is a disposition in the constitution to the formation of boils, the bowels should be kept regular, and tonics, as bark or steel, taken, with the frequent use of sea-bathing, if possible.

BOLAS. *Prep.* Into 2 lbs. of flour pour ¾ pint of warm milk, a small teacupful of yeast, and 6 eggs; make them into a dough, add 1 lb. of butter, by degrees, and let it rise for 1 hour, then mix in 1 lb. of powdered sugar, and make the mass into cakes; put these into cups or tins previously well buttered, and ornament the top with candied orange or lemon peel; lastly, bake them.

BOLUS OF ALUM. *Prep.* Powdered alum and conserve roses, of each 15 grs.; sirup of orange peel or saffron to mix. *Used* in fluxes, &c.

BOLUS OF MUSK. *Prep.* I. Musk 15 grs.; camphor 5 grs.; powdered gum 3 grs.; mix with sirup of saffron. *Use.* In convulsions and typhus fever.

II. Musk and carbonate of ammonia of each 10 grs.; conserve of roses q. s.; to make a bolus. *Use.* Sometimes given every three hours in mortification accompanied with spasms.

BOLUS, PURGING, (FOR DOGS.) *Prep.* Jalap and rhubarb, of each 15 grs.; ginger 4 grs.; soap 10 grs.; water q. s.; if this does not open the bowels, add aloes half a drachm, or 3 or 4 grs. of calomel. *Use.* In the distemper; it must be preceded by copious bleeding, and abstinence from food for a day or a night.

BOLUS OF SULPHATE OF ZINC. *Prep.* Sulphate of zinc 20 to 25 grs.; conserve of roses q. s. to make a bolus. *Use.* As an emetic where poison has been taken, to be followed by copious draughts of warm water or weak tea.

BOLETIC ACID. An acid discovered by Braconnot in the juice of the boletus pseudo-igniarius.

Prep. Concentrate the expressed juice to a sirup by means of a gentle heat, then digest it in strong alcohol, and dissolve the residuum in water; add a solution of nitrate of lead as long as any precipitate falls, which must be washed with water, diffused through water in a tall glass vessel, and in this state a current of sulphureted hydrogen must be passed through it, until the lead is thrown down; filter, evaporate, and crystallize; lastly, purify by resolution and crystallization from alcohol.

Remarks. This acid dissolves in 45 parts of alcohol and 180 of water, and is volatile. It is doubtful whether it be a distinct acid principle.

BOLOGNA VIAL. The bologna, or philosophical vial, is a small vessel of glass which has been suddenly cooled, open at the upper end, and rounded at the bottom. It is made so thick at the bottom that it will bear a smart blow against a hard body without breaking; but if a little pebble, or piece of flint, is let fall into it, it immediately cracks, and the bottom falls into pieces; but unless the pebble or flint is large and angular enough to scratch the surface of the glass, it will not break.

BOLOGNIAN PHOSPHORUS. *Syn.* BOLOGNIAN STONE. This is a phosphorescent stone that once excited great attention. It was accidentally discovered by a shoemaker of Bologna in the 17th century. A family of the name of Logani, who were very successful in making it, acquired a large fortune by selling it to the curious throughout Europe.

Prep. Powder native sulphate of baryta that has been previously ignited, and make it into a paste with mucilage of gum arabic; roll this into pieces a quarter of an inch thick, and dry them in a moderate heat; then expose them to the heat of a wind furnace by placing them loose among the charcoal.

Prop., Use, &c. Placed in a vial and exposed for a few minutes to the sun's rays, it will give light enough in the dark to see the figures on the dial-plate of a watch.

BOMBIC ACID. An acid which M. Chaussier extracted from the silkworm in 1781. It has since been found not to be a distinct acid.

BON-BONS. *Prep.* Provide leaden moulds, which must be of various shapes, and be oiled with oil of sweet almonds. Take a quantity of brown-sugar sirup in the proportion to their size, in that state called a *blow*, which may be known by dipping the skimmer into the sugar, shaking it, and

flowing through the holes, when parts of light may be seen; add a drop of any esteemed essence. If the *bon-bons* are preferred white, when the sugar has cooled a little, stir it round the pan till it grains, and shines on the surface; then pour it into a funnel and fill the little moulds, when it will take a proper form and harden: as soon as it is cold take it from the moulds; dry it for two or three days, and put it upon paper. If the *bon-bons* are required to be colored, add the color just as the sugar is ready to be taken off the fire.

BONES. The bones of animals are employed for various purposes in the arts, manufactures, and domestic economy. (See the succeeding articles.)

BONE ASH. *Syn.* Impure Phosphate of Lime. *Prep.* Calcine bones to whiteness, and reduce the ash to fine powder. *Use.* To make pure phosphate of lime, and to form cupels. It is sold for burnt hartshorn.

BONE BLACK. *Syn.* Animal Charcoal. Ivory-Black. Bones burnt in close vessels.

Prep. On the large scale, two different processes are adopted to produce bone black.

I. (*From bones as the sole product.*) The bones broken to pieces are put into small cast-iron pots of the shape of the engraving, and varying from

$\frac{3}{8}$ to $\frac{1}{2}$ an inch in thickness. Two of these being filled, are dexterously placed with their mouths together and then luted with loam. A number of vessels, thus prepared, are placed side by side and over each other, in an oven resembling a potter's kiln, to the number of 100 to 150. The fire is then kindled, and the heat kept up strongly for 10 or 12 hours, according to circumstances, until the process is completed. The whole is allowed to cool before opening the pots.

II. (*The residuum of the manufacture of Bone Spirit.*) The bones are here introduced into retorts similar to those used at the gas works, and heat being applied, the volatile products are conveyed away by iron pipes to cisterns where its condensable portion is collected. As soon as the process of distillation is finished, the solid residuum in the retorts, while still red hot, is removed through their lower ends into wrought-iron canisters, which are instantly closed by air-tight covers, and luted over. These are then raised to the ground by a crane and allowed to cool.

Remarks. Previously to distillation or calcination, the bones are boiled for their grease, which is sold to the candle and soap makers. They are then sorted, the finest pieces being selected for making handles for knives, tooth-brushes, buttons, &c.; the next sort for making into bone black; while the smallest and worst description is reserved for grinding into manure. The bones lose about $\frac{1}{2}$ their weight by the process of burning. After this they are ground in a mill, sorted by sieves into two kinds, one *granular*, somewhat resembling gunpowder, and the other *quite fine*. The one is sold under the name of *animal charcoal*, for decoloring liquors, the other as a *pigment*. This article possesses the valuable property of taking lime from sirups, at the same time that it decolors them. Its power as a decolorizer may be tested by adding it to a solution of brown sugar or molasses, or water containing $\frac{1}{1000}$ part of indigo dissolved in sulphuric acid. The test should be made in a small glass tube. By well washing and careful reburning, this charcoal may be used any number of times as a decolorizer.

BONES AND IVORY, DYES FOR. 1. (*Red.*) *a.* Make an infusion of cochineal in water of ammonia, then immerse the pieces therein, having previously soaked them for a few minutes in very weak aquafortis and water.

b. Boil the bones with 1 lb. of Brazil dust, in 1 gallon of water, for 3 hours, then add $\frac{1}{4}$ lb. of alum and boil for 1 hour more.

2. (*Black.*) *a.* Immerse the pieces in a weak solution of nitrate of silver, for a short time, then expose them to the sunlight.

b. Steep for 2 or 3 days, in a decoction made with 1 lb. of galls and 2 lbs. of logwood, then steep for a few hours in iron liquor, (acetate of iron.)

3. (*Green.*) *a.* Steep in a solution of verdigris to which a little aquafortis has been added.

b. Dissolve distilled verdigris in weak vinegar, and steep the pieces therein.

c. Steep in a solution of 2 parts of verdigris, and 1 of sal ammoniac. *Observe* not to use a metallic vessel for the above.

4. (*Purple.*) *a.* Steep in a weak solution of terchloride of gold.

b. Boil for 6 hours in a decoction of 1 lb. of logwood in $\frac{1}{2}$ gallon of water, adding more water, as it wastes by boiling, then add 2 oz. of alum, and boil for 1 hour more.

5. (*Yellow.*) *a.* Boil for 1 hour in a solution made with 1 pound of alum in 1 gallon of water, then take out the pieces and steep them in a decoction made with $\frac{1}{2}$ lb. of turmeric in 2 quarts of water; lastly, mix the two liquors and boil them therein for 1 hour.

b. Steep the pieces for 24 hours in a solution of sugar of lead, then take them out, and when dry, immerse them in a solution of chromate of potassa.

c. Dissolve as much of the best orpiment in water of ammonia or hartshorn, as it will take up, then steep the pieces therein for twenty-four hours; lastly, take them out and dry them, when they will turn yellow. *Remark.* By diluting the solution with water, any shade of yellow may be made.

6. (*Blue.*) *a.* Stain them green, then steep them in a hot and strong solution of pearlash.

b. Boil them in a strong decoction of logwood, and afterwards steep them in a solution of blue vitriol.

c. Steep them for a short time in a weak solution of sulphate of indigo, to which a little salt of tartar has been added; or, still better, boil them in a dyer's green indigo vat. *Remarks.* The bones of living animals may be dyed by mixing madder with their food. The bones of young pigeons may thus be tinged of a rose color in 24 hours, and of a deep scarlet in 3 days; but the bones of adult animals take a fortnight to acquire a rose color. The bones nearest the heart become tinged soonest. In the same way extract of logwood will tinge the bones of young pigeons purple. (Mr. Gibson.)

BONE GREASE. *Prep.* By bruising and boiling the refuse bones of the kitchen, and skimming the broth when cold, from $\frac{1}{4}$ (?) to $\frac{1}{5}$ of their

weight of good fat may be obtained, fit for culinary purposes when fresh, but always excellent for making soap and candles. (Proust.)

BONE GLUE. *Syn.* GELATINE. *Prep.* This is made by dissolving out the earth of bones, previously boiled for the grease, washing the remaining jelly with water, then boiling it with a little water, and forming it into cakes for sale. (SEE GLUE.)

BONE MANURE. For this purpose the bones are ground to a coarse powder in a mill, and sowed along with the seed in a drill. It is said that wheat thus treated yields 30 to 50 per cent. more in weight of straw and grain than by the common methods. It is usually applied to light or turnip soils, which it renders more than ordinarily productive. Bone manure is much used in the west of Yorkshire, Holderness, and Lincolnshire. The usual quantity per acre is 70 bushels, when used alone; but when mixed with ashes, as common manure of any sort, 30 bushels per acre is thought quite enough. It is applied at the same periods as other manure, and has been found in this way to remain 7 years in the ground. The rough part of this manure, after being 5 years in the ground, has been gathered off one field and thrown upon another of a different soil, and has proved, even then, good manure.

BONES, (IN COOKERY.) The bones of good meat form most excellent materials for making soups and gravies, as is well known to every good cook. In France, soup is extensively made by dissolving bruised bones in a steam heat of 2 or 3 days' continuance, and also by dissolving out the earthy part by digestion in weak muriatic acid, when a lump of gelatine is obtained, which after being well washed with water will dissolve by boiling, and is equal to isinglass for all the purposes of making soups and jellies. Proust has recommended the following process for making the best of bones, in hospitals, jails, and similar establishments:—Crush the bones small, then boil them for 15 minutes in a kettle of water, cool, and skim the fat off, which varies from $\frac{1}{6}$ to $\frac{1}{4}$ (?) of the weight of the bones employed, and when fresh is fit for all common purposes. The bones are then ground, and boiled in 8 to 10 times their weight of water, of which that already used must form a part, until $\frac{1}{2}$ is wasted, when a very nutritious jelly is obtained. A copper vessel should not be used, as the jelly acts upon this metal. An iron Papin's digester is the most suitable. The bones of boiled meat are nearly as productive as those of fresh meat, but roasted meat bones scarcely afford any jelly. (Dr. Young.) As boning meat before cooking is now a very general practice, a quantity of fresh bones may always be had.

BONE SHAVINGS. *Syn.* BONE DUST. BONE TURNINGS. These yield a beautiful jelly by boiling with water, nearly equal to that produced from hartshorn shavings, for which they are very frequently sold.

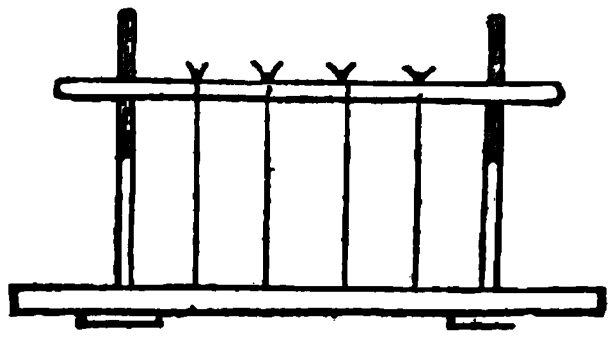
BOOKBINDING. The process of binding books may be divided into several distinct operations, which, in large establishments, are usually performed by different persons, such a method being found to produce greater expedition and better work, than when the whole is done by one person.

The sheets received from the hands of the printer are—

1. *Folded*, which is done correctly by observing the marks or catchwords at the bottom of the pages. As the sheets are folded they are laid upon each other in proper order, and are ready to undergo—

2. *The operation of beating.* This is performed by laying them upon a large stone, and striking them with a heavy smoothed-faced hammer, or by passing them through a rolling press. The former method is usually adopted in the small way, and the latter on the large scale.

3. *The sheets are next fastened to bands*, which is done by taking the folded sheets up one by one, and sewing them to pieces of cord, stretched in a little frame screwed or fastened to the counter or table, called the sewing-press. (See eng.) The



number of bands used, is generally 6 for a folio, 5 for a quarto, and so on proportionally, less than 4 seldom being employed even for small sizes. The ends of the cords being cut off to within about 2 inches of the back, the sheets are ready for—

4. *Glueing.* The back being knocked into shape with a hammer, and the sheets placed in the cutting press, which is then slightly screwed up, melted glue is thinly and evenly applied. After a short time the book is removed from the press, and the back properly adjusted with a hammer, when it is again put into the cutting press, where it is screwed up very tight, and is then ready for—

5. *Cutting.* The instrument employed for this purpose is of a peculiar shape, and called a plough or plough-knife.

6. *Affixing the boards. The bands* are now scraped out fine at the ends, and the pasteboard to form the covers is fastened thereto, and is then properly adjusted, and shaped with a large pair of shears. The edges now undergo the operation of—

7. *Sprinkling*, or other adornment. The first is performed by a stiff brush of hog's bristles, dipped in the color; the brush being held in the one hand, and the hairs moved with the other.

8. *The external covering of leather, fancy cloth, or paper*, is now applied, having been previously well soaked in paste, to make it properly adhere. One or more of the blank leaves of the book are next pasted against the inside of the cover, to screen the ends that are turned over, when the book is finished; or for choice work, is handed to a "*finisher*" for—

9. *Lettering, gilding, &c.* Gold-leaf is applied by means of white of egg, the pattern being given by pressure with heated brass tools, having the design or letters on their surfaces. The whole is then glazed over and polished.

Remarks. The succession of some of the above operations sometimes varies with the workmen and

the nature of the binding. The above must therefore only be regarded as a short and general outline of the process. If the reader will accompany the perusal by an examination of a bound book, the whole will be rendered quite familiar.

The following varieties of binding may be noticed:

a. Boards. A book, loosely done up without cutting the edges, and covered with paper or cloth, is said to be in boards.

b. Cloth-binding. This style of binding is that in which the majority of works are now issued. It admits of great neatness and even beauty, and is very durable and cheap. *Proc.* The prepared cloth, cut by a pattern to the size suited to the volume, is passed rapidly through a rolling press, between engraved cylinders of hardened steel, which print the pattern in relief. Paste is now applied to the cloth, when it is placed over the volume, previously prepared to receive it. Books in cloth-binding are not commonly cut at the edges, unless highly finished.

c. Dutch binding. This species of binding is distinguished by the backs being of vellum.

d. French binding. This consists in pasting a piece of parchment over the back of the book, between each band, and pasting the ends upon the inside of each cover.

e. Half-binding. Books forwarded in boards, and finished with leather backs and corners, are called "*half-bound.*"

f. Hancock's patent binding. In this method the sheets are folded in double leaves, and being properly placed together and adjusted, the book is subjected to the action of a press, and a strong solution of Indian rubber is smeared over the back with the finger. The operation is repeated, as often as necessary, when fillets of cloth are cemented on with the varnish, and the book is ready to have the boards attached. Thus several of the common operations of binding are dispensed with. I willingly bear testimony to the strength and durability of this method, and the great convenience it affords in allowing the books to open perfectly flat upon a table, or to be distorted in any possible manner, without injury to their backs. It is the best way of binding books for travellers. I once had a large trunk of books, among which was one bound on Hancock's plan. All the rest were nearly torn to pieces by a few months' journey, but this one was uninjured.

g. Law binding. A strong method applied to law books.

h. Leather binding. *Proc.* Immerse the leather in water; after which wring it, and stretch it on a board; place the book with the boards extended thereon, and cut out the cover, allowing about half an inch larger than the book, to turn over the inside of the pasteboards. Pare the edges of the cover very thin all round on a marble slab, and paste it well; glue the back of the book, and spread the cover on the board.

Let the pasteboards be properly squared and even; put the book on the cover, which draw on very tight. Rub the cover smooth with a folding-stick, and turn it over on the inside of the pasteboards on the fore edge. The corners on the inside must be cut and neatly pressed down; tie a piece of thread round the book, between the boards and head-bands, draw up the leather on the back, if necessary, to cover the top of the head-bands; rub the back very smooth with a flat folding-stick, and place it at a distance from the fire to dry.

Rough calf must be damped on the grain side with a sponge and water before pasting and covering.

Russia leather must be well soaked in water fo an hour, taken out, well beaten, and rubbed; afte which the paste must be well worked into the flesh side before covering.

Morocco must be grained by rubbing it on a board, with the grain side inside, and after being pasted, left to soak for a quarter of an hour, and the cover then drawn on with a piece of woollen cloth to preserve the grain.

Roan may be either soaked in water or left to soak when pasted.

i. Italian binding. This is a common variety of binding employed in Italy, (hence its name,) in which the books are covered with a kind of thick coarse paper. In Italy it is called "*alla rustica.*"

k. Marble binding. Named from the design of the exterior.

l. Palmer's patent binding. This consists in applying small brass bars, linked together, to the back of the book, in such a manner that they make the different sections of the book, when open, parallel with each other, and thus admit of writing, without inconvenience, on the ruled lines near the back.

m. School binding. The following is a strong method for school books:—When the books have been cut, colored, and backed, cut off the part of the bands intended to be laced to the pasteboards, and glue on the back a piece of strong smooth linen cloth, which must reach within half an inch of the head and foot, turning on the sides about an inch; paste the boards on each side of the cloth, fixing them close in at the groove, and give the books a firm pressing in the standing-press till dry. Square the boards, glue the backs, and cover and finish in the usual manner.

This method will secure and give strength to the joints, so as effectually to prevent the leather from breaking, and require no more time than lacing in the bands. The edges may now be colored, sprinkled, or marbled, as required.

n. William's patent binding. This consists in placing a back, of a curved form, turned a little at the edges, and made of iron, copper, brass, wood, ivory, or any other material of sufficient firmness. This back is adjusted to the book before it is bound, in such a manner that it may just cover, but not press upon the edges, and is fastened on by enclosing it in vellum or ferret wrappers, which are pasted down upon the boards or drawn through them. The effect is, to make the book open evenly and freely, and to prevent it from spreading on either side.

BOOTS, TO CLEAN. To do this in the best style always use "boot-trees," employ but little blacking, and brush it off while damp. The dirt should, of course, be carefully brushed off before applying the blacking.

BOOTS AND SHOES, WATERPROOF COMPOSITION FOR. *Prep.* Boiled oil 1 pint; oil of turpentine, black rosin, and bees' wax, of each 3 oz. *Proc.* Melt the wax and rosin, then stir in the oil, remove the pot from the fire, and when it has cooled a little, add the turpentine.

II. Take 3 oz. of spermaceti, and melt it in a pipkin, or other earthen vessel, over a slow fire; add thereto 6 drachms of Indian rubber, cut into slices, and these will presently dissolve. Then add *seriatim* of tallow 8 oz.; hog's lard 2 oz.; amber varnish 4 oz. Mix, and it will be fit for use immediately. *App.* The boots or other material to be treated, are to receive two or three coats, with a common bladking brush, and a fine polish is the result.

BOOT-TOP LIQUID. *Prep.* I. Oxalic acid and white vitriol of each 1 oz.; water 1½ pints. *Proc.* Dissolve and apply with a sponge to the leather previously washed with water, then wash the composition off with water, and dry. This liquid is poisonous.

II. Mix in a vial, 1 drachm of oxymuriate of potass, with 2 oz. of distilled water; and when the salt is dissolved, add 2 oz. of muriatic acid. Then shake well together, mix in another vial 3 oz. of rectified spirit of wine with ½ an oz. of the essential oil of lemon, unite the contents of the two vials, and keep the liquid, thus prepared, closely corked for use. This liquid should be applied with a clean sponge, and dried in a gentle heat; after which, the boot-tops may be polished with a proper brush, so as to appear like new leather.

III. Sour milk 1 quart; gum arabic 1 oz.; juice of 2 lemons; white of 2 eggs; oil vitriol 2 oz. Mix.

IV. Sour milk 1 quart; butter of antimony, cream of tartar, tartaric acid, and burnt alum, of each 2 oz. Mix.

BORACIC ACID. *Syn.* SEDATIVE SALT. SED. SALT OF VITRIOL. SED. SALT OF HOMBERG. *Prep.* Dissolve borax in 4 times its weight of boiling water, then add sulphuric acid to the solution until it acquires a distinct acid reaction, (about ½ the weight of the borax.) As the solution cools, crystals of boracic acid will be deposited. These crystals must be then placed on a filter, and washed with a little cold water. They may be still further purified by solution in boiling water and recrystallization.

Remarks. Even after this treatment, the crystals are apt to retain a little sulphuric acid or sulphate of soda, which can only be got rid of by heating them in a platinum crucible, before redissolving them and crystallizing the second time, as above described. When wanted perfectly pure for chemical analyses, this plan must be always adopted.

The boracic acid of commerce is extracted from the acid lagoons of Tuscany.

Prep. As thus obtained, this acid is soluble in 25 times its weight of cold, and 3 times its weight of boiling water. Very soluble in alcohol, which then burns with a bright green flame, offering a sure test of the presence of boracic acid. Odorless, and tastes bitter. Reddens litmus, but browns turmeric paper. It was once administered internally in large doses, (by Cullen,) but is now scarcely ever employed as a medicine.

BORATE. A compound, formed of the preceding acid and one of the bases.

Prop. The boracic acid has but a feeble affinity for the bases; most of the borates being decomposed by the stronger acids, the former being liberated in a free state. *Prep.* Many of them may be formed by digestion of the hydrate of the base in a solution of the acid, with the assistance of heat, or by double decomposition.

Tests. I. By digestion in slight excess of oil of vitriol, evaporating to dryness, powdering, and dissolving in alcohol, the latter will acquire the property of burning with a green flame. II. If to a strong and a hot solution of a borate, sulphuric acid be added in excess, crystals of boracic acid will form as the liquor cools.

BORATE OF MERCURY. *Prep.* I. Neutral borate of soda 265 grs.; calomel 222 grs.; grind together in a mortar, with a little water, then fill the mortar up with hot water; collect the red precipitate; wash and dry.

II. Add a solution of borax to a solution of quicksilver in nitric acid. Collect the precipitate as before. (White.)

BORATE OF SODA. I. (*Neutral borate.*) *Prep.* Saturate boracic acid in solution with carbonate of soda, at a boiling heat. (Berzelius.)

II. (*Biborate.*) This salt, often erroneously called borate and subborate, is the borax of commerce, and is a natural production. (See BORAX.)

BORAX. *Syn.* BIBORATE OF SODA. BORATE OF SODA. SUBBORATE OF SODA. REFINED BORAX. Crude borax is a natural production, and after being refined, forms a large portion of the borax of commerce. In its rough state it is called *crude borax*, *tincal*, *tincar*, &c. It is found crystallized on the edges and shallows of a brackish lake in Thibet, during the winter. It is also prepared by saturating the native boracic acid of Tuscany with soda. The market being literally overloaded with the former article, its price has fallen so low as to allow of its employment for this purpose with great advantage. A valuable paper on this subject, by M. Payen, appeared in the "Ann. de Chimie et de Phys." for July, 1841; and a translation of the same in "The Chemist," vol. ii. 368, to which the reader is referred for a complete account of this process.

The best Tuscany boracic acid contains only 50 per cent. of real boracic acid, and yields no more than 140 to 150 per cent. of good borax.

Prop., Use, &c. It is extensively employed as a flux for metals, for soldering, and in medicine. Internally it is diuretic, sedative, emmenagogue, and cooling, in doses of 15 to 40 grains; externally as a gargle for sore throat, and in powder as a detergent in aphthæ, and ulcerations of the mouth. Dissolved in rose-water, it is used as a cosmetic, and mixed with 8 times its weight of lard, forms a useful piles ointment.

Tests. These are the same as for the borates, which see. It reddens turmeric paper, and, before the blowpipe, fuses into glass, which may be tinged red by terchloride of gold, and blue by cobalt.

Pur. The purity and strength of borax are best ascertained by determining the quantity of sulphuric acid required to neutralize a given weight, as indicated by litmus paper. Common salt and alum are frequently mixed with borax to lower the value. The former may be detected by dissolving the borax in hot water, when a solution of lunar caustic will give a curdy white precipitate, soluble in ammonia; and the latter by water of ammonia, which will give a bulky white precipitate. The

former must be distinguished from the white pulverulent precipitate of borate of silver, which will be thrown down from pure borax.

BORAX, GLASS OF. *Prep.* Dry borax with a gentle heat, breaking down the froth as it rises, then melt it by increasing the heat until it runs into a glass. *Use.* In soldering, and as a blowpipe flux.

BORO-FLUORIDE OF HYDROGEN.—*Prep.* Pass fluoboric acid gas through water, and afterwards carefully concentrate the solution; cool and separate the crystalline powder from the solution, which is the boro-fluoride of hydrogen. *Prop., &c.* With most of the protoxides it interchanges bases, and metallic boro-fluorides result.

BORO-FLUORIDE OF BARIUM. *Prep.* Add carbonate of baryta to boro-fluoride of hydrogen, until it ceases to be dissolved; evaporate to the consistence of a sirup, when crystals will form. *Remarks.* The boro-fluoride of calcium, magnesium, and lead, may be formed in a similar way.

BORO-FLUORIDE OF POTASSIUM.—*Prep.* Drop boro-fluoride of hydrogen into a solution of carbonate of potassa, collect the white powder that falls, and wash it with cold water.

BORO-FLUORIDE OF SODIUM. *Prep.* Dissolve fluoride of sodium in boro-fluoride of hydrogen, and crystallize. *Remarks.* Boro-fluoride of lithium may also be formed in a similar way.

BORON. The base of boracic acid, discovered by Sir H. Davy, in 1807, by means of the galvanic battery of the Royal Institute.

Prep. Potassium, and perfectly dry boracic acid, or still better, boro-fluate of potassa, intimately mixed together, are to be placed in an adopter, or glass tube, and submitted to a low red heat. When cool, remove the loose cork that fastened its mouth, and pour in successive portions of hot water, until the whole matter is detached and dissolved. Collect the liquid and allow it to settle, then wash the precipitate, first with a solution of sal ammoniac, and finally, with alcohol; next dry the boron in a capsule, and put it into a well-stopped vial.

Prop., &c. A solid, tasteless, and inodorous powder, of grayish-brown color. With sulphur it unites at high temperatures, forming sulphurets; and when placed in chlorine gas it spontaneously inflames, and a gaseous chloride is produced. This gas may also be made by exposing calcined borax and charcoal at a red heat to the action of dry chlorine.

BOTTLE, RED. *Syn.* Taylor's Red Bottle. Whitworth Doctor's Red Bottle. *Prep.* British brandy 1 quart; powdered cochineal ½ oz.; oil of origanum 10 drops. Digest for 24 hours and filter.

BOUGIE. *Syn.* Candela. Candela cerea. Candelula. Virga cerea. Cerea. Cereola. Cereus. Cereolus. A long slender instrument, introduced into the urethra, œsophagus, or rectum, to overcome strictures of those canals. The word bougie is the French for a wax candle.

Prep. I. Add 3 parts of boiled linseed oil to 1 part of melted amber, and when mixed add 1 part of oil of turpentine; spread the mixture at 3 successive intervals upon loose spun silk cord or web, dry in a heat of 150°, and repeat the process until the instrument has acquired the proper size, then polish, first with pumice-stone, and afterwards with tripoli and oil.

Remarks. The above is the original receipt of the French professor Pickel, and is still generally used, slightly modified, on the continent.

II. Add to the oil and amber melted together, as last, caoutchouc in the proportion of $\frac{1}{20}$ of the weight of the oil employed; when dissolved, remove the vessel from the fire and proceed as before.

Remarks. This is the plan usually adopted at Paris, and for the best elastic bougies this process usually occupies from 6 to 8 weeks. When the bougie is wanted to be hollow, a piece of polished metallic wire is introduced into the axis of the silk, or tinfoil is rolled round the wire and the composition applied as before. When dry and hard the wire is withdrawn.

III. (*Caoutchouc, or elastic gum bougies.*) *a. In France* these are made by applying a solution of Indian rubber in ether, to the silk or foil prepared as above.

b. In England, where ether is expensive, naphtha is employed, or slips of Indian rubber previously boiled in water, or that have had their edges softened with ether, are wound round the wire or foil, and kept in their place by a piece of tape applied over them, as in making elastic tubes. They are afterwards carefully smoothed off.

IV. A common kind of bougie is made by dipping pieces of catgut or soft linen into lead plaster, melted, and rolling it while yet warm upon a slab. *Very inferior.*

V. (*White.*) *Prep.* Yellow wax 1 lb.; spermaceti 1 oz.; finely-powdered sugar of lead ½ oz.; melt and spread upon slips of old linen, then roll them up while warm with the spread side outwards.

VI. (*Bell's.*) Lead plaster 1 lb.; yellow wax 8 oz.; olive oil 2 oz.; *as last. Very inferior.*

BOUILLI. (French for boiled meat.) This name has been applied by cooks to several dishes of boiled meat, as a refinement on the plain English. Thus "beef bouilli, beef in bouilli, &c.," means, stewed or boiled beef, &c. As, however, the name is à la français, so must be the accompaniments, which generally consist of herbs and vegetable seasoning in greater quantity and variety than is usually deemed essential to a plain-spoken piece of boiled or stewed meat!

BOULES DE NANCY. Equal parts of iron filings and red tartar, made up into balls with spirit. *Use.* As a tonic dissolved in hot water.

BOUQUET DE LA REINE. *Prep.* I. Essence of bergamotte 1 drachm; English oil of lavender 23 drops; oil of cloves and aromatic vinegar, of each 8 drops; essence of musk 10 drops; alcohol ½ oz. Mix.

II. Oils of bergamotte and lavender 30 drops each; neroli 15 drops; oils of verbena and cloves, of each 5 drops. Essences of musk, ambergris, and jasmin, of each ½ drachm; rectified spirit of wine (strongest) 1 oz. Mix.

BOX WOOD MAHOGANY. *Prep.* Warm the wood by the fire, then wash it over with aquafortis, let it stand 24 hours to dry, and polish it with linseed oil reddened with alkanet root, or give it a coat of varnish, made by dissolving aloes and annotto in spirit of wine.

BOYLE'S FUMING LIQUOR. Hydrosulphuret of ammonia is usually employed and sold for this article, but the liquor prepared by Boyle's process contains an excess of sulphur. (Gay Lussac.) The properties of both are however the same.

Prep. Mix 4 parts of fresh slaked lime; 2 of sal ammoniac, and 1 of sulphur, then submit the mixture to distillation.

BRA GRAS. Tar, black rosin, and the dregs of strained rosin, melted together.

BRAIN CAKES. *Prep.* Clean, wash, blanch, and soak the brains, then beat them up with a little white pepper and salt, a sage-leaf or two, scalded and finely chopped, and the yelk of an egg; make them into small cakes or fritters, and fry them.

BRAN. The husk of wheat which immediately covers the grain, and which is left in the bolting machine. *Use.* It is largely employed by the calico printers, when diffused through hot water, to remove the coloring matter from those parts of their goods which are not mordanted. A handful mixed with a pail of warm water, forms an excellent emollient foot-bath. Infused in water, (*bran tea*,) and sweetened, it forms a popular demulcent, much used in coughs and hoarseness, and, taken in quantity, proves gently laxative. It also forms an excellent manure, and, from containing the ammoniaco-magnesian phosphate, is especially adapted for potatoes. It is frequently mixed with flour and made into bread, by the poorer orders.

BRANDY. *Syn.* Eau de Vie. Aqua Vitæ. Spiritus Gallicus. Brandy-wine. The spirituous liquor obtained by the distillation of wine. When first distilled it is colorless, and only acquires a yellowish tint from the wood of the casks, in which state it is known and sold as pale or white brandy. The deep color that it usually possesses, is imparted to it by adding a little spirit coloring, (burnt sugar or caramel,) and occasionally a little red sanders wood as well, and is intended to imitate the appearance acquired by brandy from great age, when kept in wood. The natural color, however, which the spirit receives from the cask, no matter how long it may have been in it, never exceeds an amber tint, about the common color of pale Jamaica rum; but the public taste has been gradually vitiated in this respect, until only a spirit of a lively and full "*brandy color*" (unless for a pale brandy) will sell.

The brandies most esteemed in England are imported from France, and are those of Cognac and Armagnac, the preference being generally given to the former. The brandies of Rochelle and Bordeaux may be reckoned next in quality, while those obtained from Portugal, Spain, and Italy are very inferior.

The constituents of brandy are alcohol and water, and small quantities of volatile oil, acetic acid, acetic ether, œnanthic ether, coloring matter, and tannin. It is from the presence of the last six of these substances that the spirit derives its distinguishing smell and flavor. The quantity of alcohol present in brandy varies from 48 to 55 per cent. When first imported, it is generally 1 or 2 overproof, but by age its strength is lessened, and by the time it is usually taken from the bond store for sale, seldom exceeds 3 or 4 underproof. From considerable personal acquaintance with the cognac trade, I feel confidence in asserting, that brandies of the best quality seldom exceed proof, and are generally below it, and that it is a common practice in France to add spirit of wine and coloring to raise the strength to any given point desired by the English purchaser, and to charge the same in the invoice; or where the purchaser is not *well acquainted with the subject*, and desires a strong spirit at a low rate, to sell him brandy so mixed as genuine. The very finest brandies average from 5 to 10 u. p., and never exceed about 2 u. p.; they then contain more than ½ their weight of water, and from their boiling point being higher, they come over more highly charged with essential oil, and other volatile and fragrant principles of the grape, and thus possess in a greater degree that peculiar aroma and flavor for which they are so much esteemed. French brandy or wine, distilled at a low temperature in a water bath, yields a very pure and scarcely flavored spirit.

The quality of the brandy imported from France varies considerably from that which is drunk on the continent, principally from its being *prepared*, or, as it is technically termed, "*made up*," for the London market, which means lowering it by the addition of spirit, coloring, &c. above described. The common strength at which foreign brandy is sold in England is about 11 or 12 u. p., and below 17 u. p. it becomes seizable by the excise. The strength at which it is sold and permitted in trade, is generally 10 u. p., to which it is reduced by adding water, and never less than 12 u. p., unless it be specially agreed upon. In large quantities and from bond, of course the strength depends much upon the age and quality of the spirit. A fine old brandy being, perhaps, 8 or 10 *u. p.*, while one of the last year's vintage of a commoner quality may be as strong as 2 or 1 *u. p.* But these distinctions are familiar to every experienced brandy dealer.

In France there are several varieties of this spirit distilled, which are known by names descriptive both of their quality and source. The "*eau de vie supérieure*," or *cognac brandy*, is generally obtained from pale white wines, by careful distillation, and is remarkable for its superior flavor. When kept in glass or stone bottles, it is called white cognac brandy, and the same term is also generally applied when it has been kept in casks, but has not been artificially colored; in the latter case, however, it generally acquires a pale amber tint.

The "*eau de vie ordinaire*," or *common brandy*, is distilled from high-colored white or red wines, and has generally a sp. gr. of 0·948, and varies from 22 to 27 u. p.

The "*eau de vie de marc*" is obtained from the lees of vinegar and other wines, the marc or cake of grapes from which the juice has been pressed, and the commonest red wines, fermented and distilled together by a quick fire, to drive over as much essential oil and flavoring as possible.

The "*eau de vie seconde*" is the weak spirit that passes over after the stronger spirit has been drawn off, and the receiver changed. *It is used* for common drinking, or mixed with other brandy.

The "*eau de vie à preuve d'Hollande*" is brandy about 19° Baume, or sp. gr. ·9420, the common strength at which it is retailed in France, and will stand the "*proof*" or "*bead*"

The "*eau de vie à preuve d'huile*" is the strongest brandy usually drunk; it is about 23° Baume, or sp. gr. ·918; pure olive oil will just sink in it; hence the above term.

The "*eau de vie fort*" is usually prepared by the redistillation of common brandy, keeping the first portion separate. It answers to our spirit of wine. It is made of 12 different strengths, distinguished by names, exhibiting the quantity of water required to reduce the sample to the "*preuve d'Hollande.*" The weakest is called cinq-six, or $\frac{5}{6}$, and the strongest trois-neuf, or $\frac{3}{9}$, the difference between the numerator and the denominator being the quantity of water the 3 parts of the former will take to reduce it to the "*preuve,*" when it would make 9 parts. Its sp. gr. is about ·839.

The *esprit de vin* is brandy or spirit rectified to 0·890 and upwards.

The general method of distilling brandy in France differs in no important particular from that practised in England, for grain or molasses spirit. Neither are the French workmen more skilful nor more cleanly in their operations than the English. It is the materials alone that, in this case, conduce to the superiority of the product. The quality of the brandy varies with that of the wine from which it has been distilled. Every soil, every climate, every kind of grape, produces a wine possessing some peculiarity confined to itself, and this wine on distillation produces a spirit possessing like distinctions. A large quantity of brandy is prepared in France soon after the vintage, as the juice of the poorer grapes that is unfit for wine is fermented and at once distilled. It is a general rule, in France, to distil only such wines as are unsaleable, as the profits on the wine, sold as such, are much greater than when it is converted into brandy.

The Strength of Brandy may be ascertained in the same way as alcohol, for which purpose Sike's hydrometer is used in England. In France, from the value of spirit being less, it is frequently tested by simpler methods, though great accuracy obtains, in this particular, where necessary.

Pur. Very little perfectly pure French brandy is obtained by the small consumer in England, as it is not only generally lowered a little by the wholesale dealer, but undergoes a like process at the hands of the retailer. The safest method is either to procure it direct from the bond store, without its even entering a private cellar, or to buy of some known respectable party, and to pay a price that will offer no inducement to dishonesty. If this be not done, by all means buy British brandy, which is now made of excellent quality by many of the leading houses, as *Betts, Bretts, Booth,* and *Grimble.* From the two former a single sealed bottle may be procured at the same price as by the gallon.

The importation of foreign brandy for home consumption amounts to about 1,400,000 gallons a year.

BRANDY, (REDUCED.) I. To 20 gallons of Cognac brandy add 5 gallons of the best British brandy.

II. To 72 gallons of full-flavored French brandy, add 10 gallons of spirit of wine, (58 *o. p.,*) 8 gallons of water, and 1 pint of good coloring. Rummage well up and let it stand until the next day. *Remarks.* The above reduction is generally adopted in trade, and is known by the name of "*improving.*" But such is the poverty of the palate of the English brandy drinker, that the adulteration is often not suspected, even when it is carried to double the extent of the above, which is generally exceeded in the hands of the retailer. So long, however, as the foreign spirit constitutes about half of the mixture, and was at first of decent quality and age, the infatuated Englishman smacks his lips, and cunningly holding up his glass between the light and his eye, exclaims, "*Ah! this is a drop of the real.*"

BRANDY, (BRITISH.) *Syn.* British Cognac. Imitation Cognac, &c. From the heavy duty levied on French brandy imported into England for home consumption, it has become a desideratum with the distiller (rectifier) to produce an English spirit of a similar description. For some time the attempt proved quite unsuccessful, but of late years much capital and talent have been embarked in the pursuit, and the result has proved very satisfactory. An article of British manufacture may now be purchased, at a very reasonable rate, of really respectable quality, and possessing much of the flavor and aroma of foreign brandy, while, as a beverage, it is equally wholesome. Much of the British brandy, however, that is commonly met with, is of such a wretched quality as to be quite undeserving of the name, which is evidence of the fact, that much skill and experience is required to ensure success in its manufacture. For a long time this liquor was distilled from spoilt wine and dregs of wine, both British and foreign, mixed with beer bottoms and similar articles; and when, instead of these, corn, malt, and molasses spirit were employed, it was considered as an unpardonable and wicked misuse of those articles. Modern experience has proved, however, that perfectly pure and tasteless malt spirit is the best article to form into an imitation brandy.

The following formulæ, by skilful management, will produce very good brandy, but it must be recollected that much depends on the quality of the materials employed, as well as on the operator. As the strength and quality of the ingredients, and the methods of manipulation vary, so will the result; much must therefore be left to the judgment and discretion of the artist. It offers a profitable pursuit to the ingenious and industrious chemist and rectifier.

Prep. I. Take 12 gallons of the finest flavorless malt spirit at proof, (or if of a different strength a proportionate quantity;) add thereto 5 gallons of water, $\frac{3}{4}$ lb. of the best crude red tartar or winestone, previously dissolved in 1 gallon of boiling water; $\frac{1}{4}$ pint of acetic ether; 2 quarts of good French wine vinegar; 7 lbs. of bruised French plums, and 1 or 2 gallons of wine bottoms or flavor stuff from Cognac, mix them in a fresh-emptied sherry cask, and let them stand together for 14 days, frequently rummaging up the liquor with a stick; next draw over 15 gallons of the mixture from a still furnished with an agitator. Put the rectified spirit into a clean, fresh-emptied Cognac brandy cask, and add thereto $\frac{3}{4}$ pint of tincture of catechu, 1 lb. of fresh and clean oak shavings, and about a pint of good spirit coloring. Bung close, and agitate occasionally for a few days. *Remarks.* Age improves the above article, and renders it

(provided the process be well managed) of a very superior quality. The above receipt yields 15 gallons of brandy 17 *u. p.* The following forms may also be recommended:—

II. Perfectly pure spirit, pf. 99 gallons; red tartar, dissolved, 7 lbs.; acetic ether 3 lbs.; wine vinegar 3 gallons; bruised raisins, or French plums, 7 lbs.; bitter almonds, bruised, 1 oz.; water sufficient. Dissolve the tartar in the water, then add the other ingredients, macerate as before, and draw over 120 gallons; lastly, add a few lbs. of oak shavings, 1 lb. of powdered catechu made into a paste with water and burnt-sugar coloring as before. *Remarks.* This yields 120 gallons of spirit fully 17 *u. p.*

III. Clean spirit 17 *u. p.*, 100 gallons; nitric ether 2 quarts; cassia buds, ground, 4 oz.; bitter almond meal 2 oz.; orris root, sliced, 6 oz.; powdered cloves 1 oz.; capsicum 1½ oz.; good vinegar 2 gallons; brandy coloring 1 quart; powdered catechu 1 lb.; full-flavored Jamaica rum 2 gallons. Mix well in an empty Cognac cask, and let them macerate for a fortnight, occasionally stirring. *Remarks.* The proportion of the ingredients may be varied by the skilful brewer, as much depends on their respective strengths.

IV. Good plain malt spirit, 17 *u. p.*, 100 gallons; finely-powdered catechu 12 oz.; tincture of vanilla 4 oz.; burnt-sugar coloring 1 quart; good rum 3 gallons, or more; acetic or nitric ether 2 quarts. Mix well.

V. Clean spirit, 17 *u. p.*, 89 gallons; high-flavored cognac 10 gallons; oil of cassia 1½ drachms; oil of bitter almonds, essential, ½ a drachm; powdered catechu 10 oz.; cream of tartar, dissolved, 16 oz.; Beaufoy's concentrated acetic acid 3 lbs.; sugar coloring 1 quart, or more; good rum 1 gallon. Put the whole into a fresh emptied brandy piece, and let them remain a week together, with occasional agitation, then let them stand to settle. If this mixture be distilled, the French brandy, rum, coloring, and catechu, should not be added till afterwards.

VI. To colored plain spirit at 17 *u. p.*, add a little tincture of catechu, and a sufficient quantity of essential oil, distilled from wine lees, to give it a proper flavor. This oil is obtained by distillation from the wine lees, either dried and made up into cakes, or in their wet state mixed with about 7 times their weight of water. It should be dissolved in alcohol, and kept in this state, as it is apt to lose its flavor. *Remarks.* When this process is well managed a very capital article results, but it requires considerable address to conduct it well. The spirit produced by this plan is better for distillation. The brandy from any part of the world may thus be imitated, by distilling the oil from the lees of the wines produced in the particular district. This is the only method of producing an exact imitation. A pound each of finely-powdered charcoal and ground rice has been recommended to be digested in a gallon of spirit for a fortnight. Where black tea is cheap, as in America, it is very commonly employed to impart the roughness and flavor of brandy to colored spirits.

BRANDY, CHERRY. *Prep.* I. To every gallon of brandy put an equal measure of cherries, bruised between the fingers; steep for 3 days, then express the liquor; add 2 lbs. of lump sugar, and strain for use.

II. To the above add 1 quart of raspberries, and ½ a pint of orange-flower water. *** Quality very fine.

III. Treacle 1 cwt.; spirit (45 u.p.) 41 gallons; bruised bitter almonds (more or less, to taste) 5 oz.; cloves 1 oz.; cassia 2 oz. Put the ingredients into a large cask, well mix and let them lie a month, occasionally stirring.

Remarks. Equal parts of fully ripe Morello and black cherries produce the richest cordial.

BRANDY, CARAWAY. *Prep.* I. Steep 4 oz. of bruised caraway seeds and 2 lbs. of sugar in 1 gallon of British brandy, for a fortnight.

II. Sugar 1 lb.; caraways 1 oz.; 3 bitter almonds; spirits of wine and water, of each 1 quart; (or spirit 22 u.p. ½ a gallon.) Macerate as above.

BRANDY, DANTZIC. This is distilled from rye, ground with the root of calamus aromaticus. It has a mixed flavor of orrice and cinnamon.

BRANDY, LEMON. *Prep.* I. Steep ½ lb. of fresh lemon peel and ½ a dozen lemons, cut in slices, in 1 gallon of brandy, for a week, then add 1 lb. of lump sugar.

II. Proof spirit 7 gallons; essence of lemon 3 drachms; sugar 5 lbs.; tartaric acid 1 oz., dissolved in water 2 gallons; coloring q. s. Mix, and rummage repeatedly for 14 days. *Remarks.* Sometimes milk is added to the above, in the proportion of 1 quart (boiling hot) to every gallon.

BRANDY, MALT. Malt spirit, flavored with sweet spirits of nitre and terra Japonica, and colored with treacle, or spirit coloring. (See BRIT BRANDY.)

BRANDY, ORANGE. This may be made in a similar way to lemon brandy.

BRANDY, PEACH. *Prep.* I. From peaches, by fermentation and distillation. Much used in the United States, where peaches are very cheap.

II. Bruise the peaches, then steep them in twice their weight of British brandy, or malt spirit; lastly, express the liquor.

III. Bitter almonds (bruised) 2 oz.; proof spirit (light) 10 gallons; water 3 gallons; sugar 5 or 6 lbs.; orange-flower water ½ a pint. Mix, and macerate for 14 days.

*** Color with brandy coloring, if required darker.

BRANDY, RASPBERRY. *Prep.* I. Pour as much brandy over raspberries as will just cover them; let it stand for 24 hours, then drain it off, and replace it with a like quantity of fresh spirit; after 24 hours more, drain this off and replace it with water; lastly, drain well, and press the raspberries quite dry. Next add sugar to the mixed liquors, in the proportion of 2 lbs. to every gallon, along with a ¼ of a pint of orange-flower water.

II. Mix equal parts of mashed raspberries and brandy together, let them stand for 24 hours, then press out the liquor. Sweeten as above, and add a little cinnamon and cloves, if agreeable; lastly, strain.

BRASS. An alloy of copper and zinc.

Hist. and Prep. Brass was formerly manufactured by cementing granulated copper, or copper clippings, with calcined calamine and charcoal, in crucibles, exposed to a bright heat. The alloy

was found in lumps at the bottom of the crucible on cooling. These were remelted and cast into ingots. At the present day, brass is generally made by direct union of the metals. This process requires much care, owing to the different degrees of fusibility of copper and zinc. The proper quantity of zinc is first melted, and slips of copper plunged into it, which are rapidly dissolved, as it were, and the addition is continued until an alloy is formed, somewhat difficult of fusion, when the remainder of the copper is added. The brass thus formed is broken into pieces, and remelted under charcoal, and a proper addition of either zinc or copper made, to bring it up to the color and quality desired. It is next cast into plates, or other forms, in moulds of granite. When submitted to the rolling-press for reduction to *thin* plates, it requires to undergo the operation of annealing several times.

Prep. I. (*Fine Brass.*) 2 parts of copper to 1 part of zinc. *Remarks.* This is nearly 1 equivalent each of copper and zinc, if the equivalent of the former metal be taken at 63·2; or 2 equivalents of copper to 1 equivalent of zinc, if it be taken, with Liebig and Berzelius, at 31·6.

II. Copper 4 parts, zinc 1 part. An excellent and very useful brass.

III. (*Gold-colored Brass.*) *Syn.* Red Brass. Dutch Gold. Tombac. Similor. Prince's Metal. Pinchbeck, &c.

a. Copper and zinc, equal parts.

b. Copper 2 parts; zinc 1 or 1½ parts. This is Manheim gold.

c. Copper 3 to 5½ parts; zinc 1 part. Deep colored.

Remarks. The proportion of zinc in this alloy is altered to suit the color and other properties to the purposes for which it is intended, and often varies from ⅓ to ⅕, or ⅙ of the weight of the alloy. At the celebrated works of Hegermühl, near Potsdam, the proportions are 11 parts of copper to *two* of zinc, which produces a metal which is afterwards rolled into sheets for the purpose of making Dutch leaf-gold.

BRASS, BUTTON. (*Best.*) I. Copper 8 parts; zinc 5 parts, as above.

II. (*Common.*) Copper 50 parts; zinc 40 parts; tin 4 parts; lead 6 parts.

BRASS, FOR SOLDER. *Syn.* Hard Solder. I. 12 parts of brass; 6 parts of zinc, and 1 of tin, melted together.

II. 2 parts of brass, and 1 of zinc.

III. (*Very strong.*) 3 parts of brass, and 1 of zinc.

BRASS, TURNER'S. 98 parts of brass, and 2 of lead. *Remarks.* The addition of lead improves the brass for the uses of the turner, but lessens its malleability.

BRASS, CLEANING OF. Brass and copper are best cleaned with sweet oil and tripoli, powdered bath-brick, rotten-stone, or red brick-dust, rubbed on with flannel and polished with leather. A strong solution of oxalic acid in water gives brass a fine color. Vitriol and spirits of salts make brass and copper very bright, but they very soon tarnish, and consequently require more frequent cleaning. A strong lye of roche-alum and water will also improve brass.

Brass inlaid work may be cleaned as follows:—Mix tripoli and linseed oil, and dip into it a rubber of hat, with which polish the work. If the wood be ebony or rosewood, polish it with a little finely-powdered elder-ashes; or make a paste of rotten-stone, a little starch, sweet-oil, and oxalic acid, mixed with water. The ornaments of a French clock are, however, best cleaned with bread-crumb, carefully rubbed, so as not to spoil the woodwork. Ormolu candlesticks, lamps, and branches, may be cleaned with soap and water. They will bear more cleaning than lacquered articles, which are spoiled by frequent rubbing, or by acids, or strong alkalis.

BRASS COATING. I. Brass plates and rods may be covered with a superficial coating of brass, by exposing them in a heated state to the fumes of melted zinc, at a high temperature. *Use.* For rolling into thin plates, or drawing into wire. The celebrated spurious gold wire of Lyons is thus made.

II. Vessels of copper may be coated with brass, internally, by filling them with water strongly acidulated with muriatic acid, adding some amalgam of zinc and cream of tartar, and then boiling for a short time.

BRASS-COLORED PIGMENT. *Syn.* Brass Bronze. *Prep.* I. (*Red.*) Grind copper filings, or precipitated powder of copper, with a little red ochre.

II. (*Yellow or gold-colored.*) Gold-colored brass, or Dutch leaf reduced to a very fine powder.

Remarks. Both these powders are mixed up with varnish, and used as a paint. No more should be mixed at a time than wanted for immediate use. They are also used by dusting them over any surface, previously covered with varnish to make them adhere. (See Oxide of Copper.)

BRASS-COLORED VARNISH. *Prep.* Dissolve 1 oz. each of pale shell lac and gum sandarach, in ½ a pint of rectified spirit of wine.

Use. To mix up the preceding powders.

BRASS, PASTE FOR CLEANING. *Prep.* I. Soft soap 2 oz., rotten-stone 4 oz.; beat them to a paste.

II. Rotten-stone made into a paste with sweet oil.

III. Rotten-stone 4 oz.; oxalic acid 1 oz.; sweet oil 1½ oz.; turpentine enough to make a paste.

Use. To clean brass. The first and last are best applied with a little water. The second, with a little spirits of turpentine, or sweet oil. Both require friction with soft leather.

BRASS ORNAMENTS, PRESERVATION OF. Brass ornaments, when not gilt or lacquered, may be cleansed, and a fine color given to them by two simple processes. The first is to beat sal ammoniac into a fine powder, then to moisten it with soft water, rubbing it on the ornaments, which must be afterwards rubbed dry with bran and whiting. The second is to wash the brass-work with roche alum boiled to a strong lye, in the proportion of an ounce to a pint; when dry, it must be rubbed with fine tripoli. Either of these processes will give to brass the brilliancy of gold.

BRASS STAIN. I. Cut sheet-brass into small pieces, and expose it to a strong heat for 2 or 3 days, then powder it, and again expose it for several days to a like heat; again powder and sift,

and expose it a third time to heat, testing it occasionally, to see if it be properly burnt. When this is the case, a little of it fused with glass will make the latter swell and froth up.

Uses, &c It imparts to glass a green tint, passing into torquoise.

II. Calcine equal parts of plate-brass and sulphur, stratified together in a crucible, until they become friable; then powder and expose them again, as last.

Use. Imparts a calcedony red or yellow tinge to glass by fusion, according to the mode of using it.

BRAWN, CHOICE. When young, the horny parts feel moderately tender; if the rind be hard, it is old.

BRAWN, MOCK. *Prep.* Take the head and belly piece of a young porker, well saltpetred; split the head and boil it; take out the bones and cut it to pieces; then take four ox-feet boiled tender, and cut them in thin pieces; lay them in the belly piece, with the head cut small; roll it up tight with sheet tin, and boil it four or five hours. When it comes out, set it up on one end, put a trencher on it within the tin, press it down with a large weight, and let it stand all night. The next morning take it out of the tin, and bind it with a fillet, put it into cold salt and water, and it will be fit for use; it will keep a long time, if fresh salt and water are put into it every four days.

BRAZIL WOOD. *Syn.* Sapan Wood. Saint Martha Wood. Fernambuca. This wood is much used in dyeing. A decoction is made by boiling for some hours in hard spring water, and this is generally kept for some time, or until it undergoes a species of fermentation, as it is thus found to yield more permanent and beautiful colors than when employed quite new. *Use.* To dye *red.*

BRAZIL WOOD DYE. I. (*For cotton and linen.*) *a.* First boil the goods in a bath of sumach, next work them through a weak mordant of solution of tin, and then run them through the Brazil bath, lukewarm. This gives a bright red.

b. First alum the goods and rinse them, then give them a mordant of solution of tin, rinse again, and turn them through the dye-bath. This gives a rose color.

Remarks. The shades of this dye may be varied by the strength of the bath, mordant, &c. A little alum added to the Brazil-bath, gives a purple tint. 1 lb. of Brazil wood, ½ oz. of alum, and 2 oz. of tartar will dye 20 to 25 lbs. of cotton.

II. (*For silk.*) The silk, after being well alumed in the same way as wool, but at a lower temperature, is rinsed, and passed through the decoction of Brazil, just lukewarm.

Remarks. By adding a little alkali to the bath, or by passing the silk through a water holding a little alkali in solution, after it is dyed, will produce what is called the false crimson. When wanted of a very deep crimson, a little logwood is added to the Brazil-bath. In this way any shade of color may be produced.

III. (*For wool.*) Boil the wool in water holding in solution 5 parts of alum and 1 of tartar, for 1 hour; then let it lie in the cold liquor for several days, frequently moving it about; lastly, boil it in a decoction of Brazil for ½ an hour.

BRAZILINE. *Syn.* Brezilinе. The coloring principle of Brazil wood, obtained by Chevreul in small orange-colored needles. It is soluble in both water and alcohol; alkalis turn it violet, acids yellow. With alum it dyes red.

BRAZING. The operation of uniting the edges of pieces of copper, brass, iron, &c., by means of hard solder.

Proc. The edges, after being filed quite clean, are covered with a mixture of hard solder and powdered borax, made into a paste with water. The whole is then allowed to dry, and afterwards exposed in a clear fire to a heat sufficient to melt the solder.

Remarks. In some cases a little silver is added to the solder, when it receives the name of "*silver solder.*"

BREAD. *Principles of bread-making, &c.* This most important article of food is made of the flour of different grains, but only those that contain gluten admit of conversion into light spongy bread. Hence it is that wheat flour is best calculated for this purpose. When flour is made into a stiff paste or dough with water, and rolled into cakes and baked, it forms biscuits, or unleavened bread, which was once the only description known. When the dough, previously to baking, is left for some time in a moderately warm place, varying from 80° to 120°, a state of fermentation comes on, formerly called the panary fermentation, but which is, in reality, the sugar of the flour gradually undergoing the process of conversion into alcohol, and resembles in every respect the same change which takes place in the manufacture of wine, beer, &c. During this process, a large quantity of carbonic acid gas is liberated, and the toughness of the dough preventing its escape, the whole mass becomes puffed up and spongy, and a light porous paste is formed, ready for baking into bread. The natural process of fermenting the dough just described, is, however, subject to much uncertainty, and is inconvenient from the time it occupies to complete it, and the tendency the dough has to run into the acetous fermentation, when it acquires a sour and disagreeable taste, and is rendered less nutritious and easy of digestion. This has led to the use of a *ferment*, which at once excites a proper state of fermentation throughout the mass, and speedily renders it light and spongy. *Leaven* or *dough*, already in a state of fermentation, was originally employed for this purpose, and the bread so made was hence called *leavened bread.* But this has been wholly superseded by barm or yeast. Thus it will be seen that all that is essential to make a loaf of bread, is to add a proper quantity of yeast to the dough, and to allow it to remain for a short time in a warm place, until it rises or becomes spongy, when it must be subjected to the operation of baking. If the process be well managed, and the flour be good, bread of superior quality will be produced.

Process of making bread. In preparing his dough, the modern baker takes a part of the water needed for the batch, and having warmed it to a temperature of about 80° or 90°, dissolves his salt therein, and then adds the yeast and a portion of the flour. These he works up into a dough, which he sets aside in a warm place usually provided for

the purpose, and called the "*kneading trough*," where it soon begins to ferment and swell up. This process is called "*setting the sponge*," and according to the proportion the water in it bears to the whole quantity that is to be used, it receives the name of "*whole*," "*half*," or "*quarter sponge*." The evolution of carbonic acid in the process of fermentation, causes the sponge to heave and swell, and when the surface bursts, it subsides, and then swells again and again in a similar manner. This action would go on for some time, if not interfered with; but the baker is careful to stop it before it has communicated a sourness to the mass. After the *first*, or at the *furthest*, after the second or *third* "*dropping of the sponge*," he adds the remaining quantity of flour, water, and salt, necessary to form the batch. These he incorporates by long and laborious kneadings, until the entire mass acquires uniformity, and is sufficiently tough and elastic to bear the pressure of the hand without adhering to it. The dough is now left to itself for a few hours, during which time fermentation goes on, after which the inflated mass is again kneaded, when it is ready to be cut into pieces and weighed. These pieces are then shaped into loaves, and set aside for an hour or two, during which time they swell up to nearly double their former size; they are then placed in the oven and baked. During this operation they continue for a time to increase in size, in consequence of the dilation of the pent-up gas by the heat of the oven, until at length the fermentation is checked, and the dough becomes too solid to admit of further alteration.

Remarks. A number of other processes are used by cooks and confectioners to make the different varieties of fancy bread, cakes, puddings, &c., most of which vary according to the peculiar characteristic it is desired to communicate to them. Thus some kinds of cakes and pastes are made to eat "*short*," as it is called, or are rendered less tenacious, and a species of brittleness imparted to them by the addition of starch and sugar. In pastry a similar effect and peculiar lightness is produced by butter or lard, while in some articles, white of egg, gum-water, isinglass, and other adhesive substances are added to produce an exceedingly light and porous mass.

The different varieties of bread made in England vary chiefly in their quality, according to the flour of which they are formed. *The best white bread* is made from the purest wheat flour; *ordinary wheaten bread*, of flour to which a little of the finest bran has been added; *seconds*, from flour containing a still larger portion of bran; and common household bread, from flour produced by grinding the whole substance of the grain without any separation of the bran. Symnel bread, manchet or roll bread, and French bread are varieties made of the purest flour, from the finest wheat, a little milk being usually added for rolls, and butter and eggs for choicer purposes. Several other minor kinds of bread are also made, varied by the addition of sundry trifles, as sugar, currants, and other palatable ingredients. The Scotch "short bread" is made from a *very thick dough*, to which butter, sugar, orange-peel, and spices, are added. (See GINGERBREAD.)

In France a number of different kinds of bread are made. The "*pain bis*" is the coarsest sort, and is made of a mixture of groats and wheat flour; the "*pain bis blanc*" is made of a mixture of oatmeal and wheat flour; the "*pain blanc*" of flour from which the finest portion has been sifted; the "*pain mollet*," or soft bread, is made of the purest wheat flour, from the finest grain; the "*pain chaland*," made from the same materials as the last, but the paste is pounded; the "*pain chapalé*" is a small variety of bread, similar to the French or roll bread of England; the "*pain cornu*" is a kind of small bread, named from being done up into four-cornered pieces; the "*pain de la reine*" is another variety of small bread, and the "*pain gruau*" is a bread which has been made of late years in Paris, prepared from the small granular particles separated from the best wheat after a slight grinding. The French have also their soup bread and their country white bread, besides several other varieties, not mentioned in the above list.

In the manufacture of white bread from damaged or inferior flour, a large quantity of alum is employed by the bakers, but with the best flour no alum is required. The utmost beauty, sponginess, and sweetness, may be given to bread without the addition of one particle of alum, provided the best materials are employed. As such is not, however, generally the case, it is a common practice with the bakers to introduce 4 or 5 oz. of alum to every sack of flour, or about 1 oz. to each bushel. The method of detecting this adulteration will be presently explained. The proper quantity of salt to be used is 6 or 7 lbs. to the sack, or 1¼ lbs. to the bushel. 1 sack of the best flour, and 6 lbs. of salt, ought to yield about 360 lbs. of *good bread*, and a sack of seconds 345 to 350 lbs. of bread.

Wheaten bread, made of pure materials, is one of the most wholesome articles of food, and has been justly termed the staff of life. When well fermented and baked, it is very easy of digestion. It should never be eaten till it has stood 24 hours after being taken out of the oven, as newer bread is apt to disagree with the stomach, frequently producing flatulence, heartburn, and indigestion.

Adult. This is often carried to a fearful extent: Mr. Accum says, "The bakers' flour is very often made of the worst kinds of damaged foreign wheat, and other cereal grains mixed with them in grinding the wheat into flour. In this capital, no fewer than six distinct kinds of wheaten flour are brought into the market. They are called fine flour, seconds, middlings, fine middlings, coarse middlings, and twenty-penny flour. Common garden beans and peas are also frequently ground up among the London bread flour.

"The smallest quantity of alum that can be employed with effect to produce a white, light, and porous bread, from an inferior kind of flour, I have my own baker's authority to state, is from 3 to 4 oz. to a sack of flour weighing 240 lbs."

"The following account of making a sack of five bushels of flour into bread, is taken from Dr. P. Markham's 'Considerations on the Ingredients used in the Adulteration of Flour and Bread,' (p. 21:) 5 bushels of flour; 8 oz. of alum; 4 lbs. of salt; ½ gallon of yeast, mixed with about 3 gallons of water.

"Another substance employed by fraudulent

weight of good fat may be obtained, fit for culinary purposes when fresh, but always excellent for making soap and candles. (Proust.)

BONE GLUE. *Syn.* GELATINE. *Prep.* This is made by dissolving out the earth of bones, previously boiled for the grease, washing the remaining jelly with water, then boiling it with a little water, and forming it into cakes for sale. (SEE GLUE.)

BONE MANURE. For this purpose the bones are ground to a coarse powder in a mill, and sowed along with the seed in a drill. It is said that wheat thus treated yields 30 to 50 per cent. more in weight of straw and grain than by the common methods. It is usually applied to light or turnip soils, which it renders more than ordinarily productive. Bone manure is much used in the west of Yorkshire, Holderness, and Lincolnshire. The usual quantity per acre is 70 bushels, when used alone; but when mixed with ashes, as common manure of any sort, 30 bushels per acre is thought quite enough. It is applied at the same periods as other manure, and has been found in this way to remain 7 years in the ground. The rough part of this manure, after being 5 years in the ground, has been gathered off one field and thrown upon another of a different soil, and has proved, even then, good manure.

BONES, (IN COOKERY.) The bones of good meat form most excellent materials for making soups and gravies, as is well known to every good cook. In France, soup is extensively made by dissolving bruised bones in a steam heat of 2 or 3 days' continuance, and also by dissolving out the earthy part by digestion in weak muriatic acid, when a lump of gelatine is obtained, which after being well washed with water will dissolve by boiling, and is equal to isinglass for all the purposes of making soups and jellies. Proust has recommended the following process for making the best of bones, in hospitals, jails, and similar establishments:—Crush the bones small, then boil them for 15 minutes in a kettle of water, cool, and skim the fat off, which varies from $\frac{1}{8}$ to $\frac{1}{4}$ (?) of the weight of the bones employed, and when fresh is fit for all common purposes. The bones are then ground, and boiled in 8 to 10 times their weight of water, of which that already used must form a part, until $\frac{1}{2}$ is wasted, when a very nutritious jelly is obtained. A copper vessel should not be used, as the jelly acts upon this metal. An iron Papin's digester is the most suitable. The bones of boiled meat are nearly as productive as those of fresh meat, but roasted meat bones scarcely afford any jelly. (Dr. Young.) As boning meat before cooking is now a very general practice, a quantity of fresh bones may always be had.

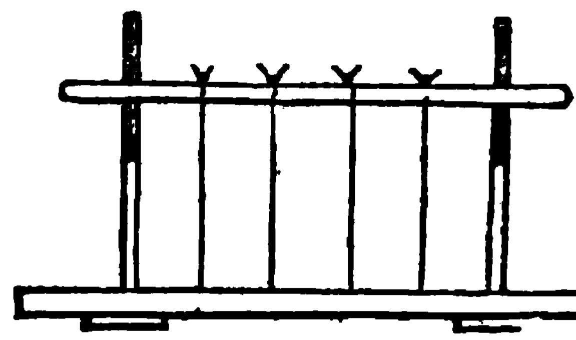
BONE SHAVINGS. *Syn.* BONE DUST. BONE TURNINGS. These yield a beautiful jelly by boiling with water, nearly equal to that produced from hartshorn shavings, for which they are very frequently sold.

BOOKBINDING. The process of binding books may be divided into several distinct operations, which, in large establishments, are usually performed by different persons, such a method being found to produce greater expedition and better work, than when the whole is done by one person. The sheets received from the hands of the printer are—

1. *Folded*, which is done correctly by observing the marks or catchwords at the bottom of the pages. As the sheets are folded they are laid upon each other in proper order, and are ready to undergo—

2. *The operation of beating*. This is performed by laying them upon a large stone, and striking them with a heavy smoothed-faced hammer, or by passing them through a rolling press. The former method is usually adopted in the small way, and the latter on the large scale.

3. *The sheets are next fastened to bands*, which is done by taking the folded sheets up one by one, and sewing them to pieces of cord, stretched in a little frame screwed or fastened to the counter or table, called the sewing-press. (See eng.) This



number of bands used, is generally 6 for a folio, 5 for a quarto, and so on proportionally, less than 4 seldom being employed even for small sizes. The ends of the cords being cut off to within about 2 inches of the back, the sheets are ready for—

4. *Glueing*. The back being knocked into shape with a hammer, and the sheets placed in the cutting press, which is then slightly screwed up, melted glue is thinly and evenly applied. After a short time the book is removed from the press, and the back properly adjusted with a hammer, when it is again put into the cutting press, where it is screwed up very tight, and is then ready for—

5. *Cutting*. The instrument employed for this purpose is of a peculiar shape, and called a plough or plough-knife.

6. *Affixing the boards*. *The bands* are now scraped out fine at the ends, and the pasteboard to form the covers is fastened thereto, and is then properly adjusted, and shaped with a large pair of shears. The edges now undergo the operation of—

7. *Sprinkling*, or other adornment. The first is performed by a stiff brush of hog's bristles, dipped in the color; the brush being held in the one hand, and the hairs moved with the other.

8. *The external covering of leather, fancy cloth, or paper*, is now applied, having been previously well soaked in paste, to make it properly adhere. One or more of the blank leaves of the book are next pasted against the inside of the cover, to screen the ends that are turned over, when the book is finished; or for choice work, is handed to a "*finisher*" for—

9. *Lettering, gilding, &c.* Gold-leaf is applied by means of white of egg, the pattern being given by pressure with heated brass tools, having the design or letters on their surfaces. The whole is then glazed over and polished.

Remarks. The succession of some of the above operations sometimes varies with the workmen and

the nature of the binding. The above must therefore only be regarded as a short and general outline of the process. If the reader will accompany the perusal by an examination of a bound book, the whole will be rendered quite familiar.

The following varieties of binding may be noticed:

a. Boards. A book, loosely done up without cutting the edges, and covered with paper or cloth, is said to be in boards.

b. Cloth-binding. This style of binding is that in which the majority of works are now issued. It admits of great neatness and even beauty, and is very durable and cheap. *Proc.* The prepared cloth, cut by a pattern to the size suited to the volume, is passed rapidly through a rolling press, between engraved cylinders of hardened steel, which print the pattern in relief. Paste is now applied to the cloth, when it is placed over the volume, previously prepared to receive it. Books in cloth-binding are not commonly cut at the edges, unless highly finished.

c. Dutch binding. This species of binding is distinguished by the backs being of vellum.

d. French binding. This consists in pasting a piece of parchment over the back of the book, between each band, and pasting the ends upon the inside of each cover.

e. Half-binding. Books forwarded in boards, and finished with leather backs and corners, are called "*half-bound.*"

f. Hancock's patent binding. In this method the sheets are folded in double leaves, and being properly placed together and adjusted, the book is subjected to the action of a press, and a strong solution of Indian rubber is smeared over the back with the finger. The operation is repeated, as often as necessary, when fillets of cloth are cemented on with the varnish, and the book is ready to have the boards attached. Thus several of the common operations of binding are dispensed with. I willingly bear testimony to the strength and durability of this method, and the great convenience it affords in allowing the books to open perfectly flat upon a table, or to be distorted in any possible manner, without injury to their backs. It is the best way of binding books for travellers. I once had a large trunk of books, among which was one bound on Hancock's plan. All the rest were nearly torn to pieces by a few months' journey, but this one was uninjured.

g. Law binding. A strong method applied to law books.

h. Leather binding. *Proc.* Immerse the leather in water; after which wring it, and stretch it on a board; place the book with the boards extended thereon, and cut out the cover, allowing about half an inch larger than the book, to turn over the inside of the pasteboards. Pare the edges of the cover very thin all round on a marble slab, and paste it well; glue the back of the book, and spread the cover on the board.

Let the pasteboards be properly squared and even; put the book on the cover, which draw on very tight. Rub the cover smooth with a folding-stick, and turn it over on the inside of the pasteboards on the fore edge. The corners on the inside must be cut and neatly pressed down; tie a piece of thread round the book, between the boards and head-bands, draw up the leather on the back, if necessary, to cover the top of the head-bands; rub the back very smooth with a flat folding-stick, and place it at a distance from the fire to dry.

Rough calf must be damped on the grain side with a sponge and water before pasting and covering.

Russia leather must be well soaked in water fo an hour, taken out, well beaten, and rubbed; afte which the paste must be well worked into the flesh side before covering.

Morocco must be grained by rubbing it on a board, with the grain side inside, and after being pasted, left to soak for a quarter of an hour, and the cover then drawn on with a piece of woollen cloth to preserve the grain.

Roan may be either soaked in water or left to soak when pasted.

i. Italian binding. This is a common variety of binding employed in Italy, (hence its name,) in which the books are covered with a kind of thick coarse paper. In Italy it is called "*alla rustica.*"

k. Marble binding. Named from the design of the exterior.

l. Palmer's patent binding. This consists in applying small brass bars, linked together, to the back of the book, in such a manner that they make the different sections of the book, when open, parallel with each other, and thus admit of writing, without inconvenience, on the ruled lines near the back.

m. School binding. The following is a strong method for school books:—When the books have been cut, colored, and backed, cut off the part of the bands intended to be laced to the pasteboards, and glue on the back a piece of strong smooth linen cloth, which must reach within half an inch of the head and foot, turning on the sides about an inch; paste the boards on each side of the cloth, fixing them close in at the groove, and give the books a firm pressing in the standing-press till dry. Square the boards, glue the backs, and cover and finish in the usual manner.

This method will secure and give strength to the joints, so as effectually to prevent the leather from breaking, and require no more time than lacing in the bands. The edges may now be colored, sprinkled, or marbled, as required.

n. William's patent binding. This consists in placing a back, of a curved form, turned a little at the edges, and made of iron, copper, brass, wood, ivory, or any other material of sufficient firmness. This back is adjusted to the book before it is bound, in such a manner that it may just cover, but not press upon the edges, and is fastened on by enclosing it in vellum or ferret wrappers, which are pasted down upon the boards or drawn through them. The effect is, to make the book open evenly and freely, and to prevent it from spreading on either side.

BOOTS, TO CLEAN. To do this in the best style always use "boot-trees," employ but little blacking, and brush it off while damp. The dirt should, of course, be carefully brushed off before applying the blacking.

BOOTS AND SHOES, WATERPROOF COMPOSITION FOR. *Prep.* Boiled oil 1 pint; oil of turpentine, black rosin, and bees' wax, of each 3 oz. *Proc.* Melt the wax and rosin, then stir in the oil, remove the pot from the fire, and when it has cooled a little, add the turpentine.

Remarks. The first two articles are applied to the leather by the tip of the finger or a sponge, and allowed to dry out of the dust, and are only adapted for clean, dry weather, or indoors. The last is laid on and polished with a brush, and then left for a few hours to harden. It may also be used to revive the faded black leather seats and backs of old chairs. All of these possess great brilliancy for a time.

BLACKING, (FOR HARNESS, &c.) *Prep.* Melt 2 oz. of mutton suet with 6 oz. of bees'-wax; add 6 oz. of sugar-candy, 2 oz. of soft soap dissolved in water, and 1 oz. of indigo finely powdered; when melted and well mixed, add a gill of turpentine. Lay it on the harness with a sponge, and polish off with a brush.

BLACKING, (FOR BOOTS AND SHOES.)

I. (*Liquid.*) *Prep. a.* Ivory-black, in fine powder, 1 lb.; treacle ¾ lb.; sweet oil 2 oz.; beer and vinegar, of each, 1 pint. *Proc.* Rub together the first three until the oil be perfectly "*killed,*" then add the beer and vinegar.

b. Ivory-black and treacle, of each 1 lb.; sweet oil and oil of vitriol, of each ¼ lb. *Proc.* Mix the first three as before, then gradually add the vitriol, diluted with thrice its weight of water; mix well, and let it stand for 3 hours, when it may be reduced to a proper consistence with water or sour beer.

c. Ivory-black and treacle, of each ½ lb; oil of vitriol 1 oz.; sweet oil 2 oz.; sour beer 1 pint; as above.

d. Ivory-black 7 lbs.; treacle 6 lbs.; sweet oil 1 lb.; oil of vitriol ½ lb.; water q. s., as last.

e. Ivory-black 3 cwt.; crude molasses 2 cwt.; linseed oil 3 gallons; oil of vitriol 20 lbs.; water q. s., as last.

II. (*Paste.*) *Prep. a.* Treacle 1 lb.; ivory-black 1½ lbs.; sweet oil 2 oz.; rub together as before, then add a little lemon juice or strong vinegar.

b. Ivory-black 2 lbs.; treacle 1 lb.; olive oil and oil of vitriol, of each ¼ lb.; water q. s., as before.

c. Ivory-black 28 lbs.; treacle 21 lbs.; common oil 1 quart; oil of vitriol 3 lbs.; water q. s.

d. Ivory-black 3 cwt.; common treacle 2 cwt.; linseed oil and vinegar bottoms, of each 3 gallons; oil of vitriol ½ cwt.; water q. s.

Remarks. The manipulations required for paste and liquid blacking are the same, the difference in the two being the quantity of liquid added. Thus, by diluting paste blacking with water or beer bottoms, it may be converted into liquid blacking of a similar quality, and, by using less fluid matter, the ingredients of liquid blacking will produce paste blacking. One thing must, however, be observed, and that is, that the ivory-black used for liquid blacking must be reduced to a much finer powder than for paste blacking, as, if this be not attended to, it will settle to the bottom, and be with difficulty diffused again through the liquid. For those persons who do not like the use of blacking containing oil of vitriol, the first of the above forms, either for paste or liquid, may be adopted. The vitriol, however, greatly contributes to promote the shining properties of the blacking, and in small quantities is not so injurious to the leather as has been falsely represented, as it wholly unites itself to the lime of the phosphate contained in the ivory-black, and is thus partly neutralized. This is the reason why *lamp-black* should *never* be employed for blacking, as it has no earthy base to absorb or neutralize the acid, which would then prove very hurtful to the leather. Oil of vitriol is now employed in the manufacture of all the most celebrated shining blackings. The addition of white of eggs, isinglass, gum arabic, and similar articles to blacking, always proves injurious, as they tend to stiffen the leather and to make it crack.

BLACK, JAPAN. *Syn.* BITUMINOUS VARNISH. *Prep.* Fuse by a gentle heat 12 oz. of amber, and 2 oz. of asphaltum, then add 2 oz. of black rosin, and ½ a pint of boiled oil; mix well, remove it from the fire, and when nearly cold, add ¾ pint of spirit of turpentine; mix well together. *Use.* To varnish metals.

BLACK, IVORY. *Syn.* COLOGNE BLACK. CASSEL BLACK. *Prep.* Put into a crucible, surrounded by burning coals, fragments or turnings of ivory, or of the osseous parts of animals, and cover it closely. The ivory or bones, by exposure to the heat, will be reduced to charcoal. When no more smoke is seen to pass through the joining of the cover, leave the crucible over the fire for half an hour longer, or until it has completely cooled. There will then be found in it a hard carbonaceous matter, which must be pounded and ground on porphyry with water, washed on a filter with warm water, and dried. Before it is used it must be again subjected to grinding. *Remarks.* Black furnished by bones is reddish. That produced by ivory is more beautiful. It is brighter than black obtained from peach stones. When mixed in a proper dose with whitelead, it forms a beautiful pearl gray Ivory-black has a very deep and rich color. The Cologne and Cassel blacks are formed from ivory.

BLACK, LAMP. *Prep.* I. Suspend over a lamp a conical funnel of tin plate, having above it a pipe to convey from the apartment the smoke which escapes from the lamp. Large mushrooms, of a very black carbonaceous matter, and exceedingly light, will be formed at the summit of the cone. This carbon is reduced to such a state of division, as cannot be given to any other matter, by grinding it on a piece of porphyry. This black goes a great way in every kind of painting. It may be rendered less oily and drier by calcination in close vessels.

The funnel should be united to the pipe, which conveys off the smoke, by means of wire, because solder would be melted by the flame of the lamp.

II. This article was originally prepared by burning oil in lamps and collecting the soot in a funnel inverted over it, as above described. Hence the name. It is now, however, generally made on the commercial scale, by burning the oil of bones or common coal tar, previously freed from its ammonia, and receiving the smoke in a suitable chamber. In the patent process of Messrs. Martin and Grafton, the coal tar is violently agitated with lime water, until the two are well mixed, after which it is allowed to subside, and the lime water being drawn off, it is washed several times with hot water. After the whole of the water has been removed by subsidence and decantation, it is put into stills, and heat applied until the impurities have passed over, and the spirit runs clear and smooth. The receiver is then charged, and the heat raised sufficiently high to drive over the whole of the oil

and spirit, leaving only the asphaltum in the still. The tar or liquor in the receiver is then put into a long cast-iron tube, furnished with numerous large burners, underneath which is a furnace to heat the pipe to nearly the boiling point. Over each burner is a sort of funnel, which goes into a cast-iron pipe or main, and which receives the smoke in a similar way from all the burners. From this the smoke is conveyed by large pipes to a box, where the heaviest part of the black is deposited; from this it is carried by pipes to a second box, where another deposite takes place, and from this box the pipe is continued until it passes into a series of large canvass bags, arranged side-by-side, and connected together at top and bottom alternately. Fifty or eighty of these bags are employed, the last one being left open to admit of the escape of the smoke, which has thus been made to traverse a space of about 400 yards. As soon as the bags contain any considerable quantity of black, they are removed and emptied. The black deposited in the last bag is the finest and best, and it becomes progressively coarser as it approaches the furnace.

BLACKLEAD. *Syn.* PLUMBAGO. CARBURET OF IRON? *Qual. Use, &c.* The best blacklead comes from Cumberland, and is used for making pencils for artists. The coarser sorts are employed to impart a metallic lustre to other bodies, and mixed with grease to diminish friction. Blacklead is also used to cover the face of articles on which it is desired to deposite a coating of copper by the electrotype. It has been used in herpes, and some chronic skin diseases, in the form of an ointment, made with 4 times its weight of lard.

BLACK, PEACHSTONE. The stones or kernels of peaches, cherries, and other similar kinds of fruit, burned in close vessels, then ground and washed well. *Use.* It works well with oil; mixed with white lead and oil it makes old gray.

BLACK, PITCOAL. The best coal for this purpose is that which has a shining fracture. It affords, perhaps, the most useful brown the artist can place on his palette; being remarkably clear, not so warm as Vandyke-brown, and serving as a shadow for blues, reds, or yellows, when glazed over them. It seems almost certain that Titian made large use of this material. Coal, when burned to a white heat, then quenched in water, and ground down, gives an excellent blue-black.

BLACK REVIVER. *Syn.* PARIS'S ANTICARDIUM. *Prep.* I. Blue galls, bruised, 4 oz.; logwood, copperas, iron filings, and sumach, of each 1 oz.; vinegar 1 quart. *Proc.* Macerate in a close vessel, with heat, for 24 hours, then strain off the clear, add the filings and copperas, and shake it occasionally for a week. Keep it in a corked bottle.

II. Bruised blue galls 1½ lbs.; logwood ½ lb.; copperas 6 oz.; vinegar 1 quart; water 3 quarts. As above.

III. Galls 1 lb.; logwood 2 lbs.; copperas ½ lb.; boil for 2 hours in water 5 quarts, until reduced to a gallon, and strain. *Use.* To restore the color of black cloth.

BLACK, RUSSIAN. *Syn.* RUSSIAN LAMP-BLACK. Prepared by burning the chips of resinous deals, and collecting the black matter deposited by the smoke. It is a good black pigment, but apt to take fire spontaneously if left for some time moistened with oil.

BLACK, RICE. Prepared by burning rice in close vessels. The color is very poor.

BLACK, SPANISH. *Syn.* CORK BLACK. Cork burnt in close vessels, and the charcoal ground and washed with water. A good color, and works very soft.

BLACK, SOOT. The soot of coal fires, ground and sifted. Used as a common paint; mixed with Venetian red and oil, it makes a chocolate color; also used to make gray mortar.

BLACK, SUGAR. *Syn.* JAMAICA BLACK. Prepared by burning sugar in close vessels. It works free, but is deficient in body. It is a warm color for washing drawings, and equal in mellowness to Indian ink and bistre.

BLACK, VINE TWIG. *Prep.* From vine twigs, by calcination as above. With whitelead and oil it produces beautiful shades of silver gray and white.

BLACK, WHEAT. From wheat burnt in close vessels. *Remarks.* A superior black, between ivory and lamp-black; it has a full body and dries hard and quickly with oil.

BLADDERS. *Prep. &c.* These articles are prepared by cutting off the fat and loose membranes attached to them, and washing them first in a weak solution of chloride of lime, and afterwards in clear water; they are then blown out and submitted to pressure by rolling them under the arm, by which they become considerably larger; they are next blown quite tight, dried, and tied up in dozens for sale. *Use.* Employed by druggists and oil and colormen to tie over pots, bottles, and jars, and to contain pill masses, and other similar substances. *Caution.* Never buy bladders unless they are perfectly dry and tight, as, if the reverse be the case, they will neither keep nor prove sound.

BLANCHING OR WHITENING. An operation in cookery, performed by putting tongues, palates, meat, &c., into cold water, when it is gradually brought to boil, and the article taken out and plunged into cold water, where it is left until quite cold. It is intended to impart whiteness, plumpness, and softness.

BLANC, (IN COOKERY.) A compound, formed by mixing 1 lb. of grated bacon, 1 lb. of suet, ½ lb. of butter, 2 lemons, 3 or 4 carrots cut into dice, 3 or 4 onions, and a little water, and boiling them until done.

BLANCMANGE, (IN COOKERY.) Jelly, seasoned and made up into forms. *Prep.* I. Isinglass 1 oz.; sweet almonds, 12 in no.; bitter do. 6 in no.; milk 1 quart. *Proc.* Boil the isinglass and almonds grated in the milk, until of a proper consistence when cold; then strain it, and when nearly cold pour it into the moulds, previously rubbed with a little salad oil, and then wiped out again.

II. To the above add ½ lb. of lump sugar and 4 tablespoonfuls of cream; when cold, remelt it and add a tablespoonful of orange flower water, after which it may be moulded as before.

III. Use calves' feet jelly instead of isinglass.

IV. (MRS. HOFFMAN'S.) Isinglass ½ lb.; rosewater ½ pint; milk 2 quarts; milk of almonds ½ pint.

V. (*Rice.*) Ground rice 2 oz.; milk 1 pint; lump sugar 3 oz.; a little lemon peel and cinnamon; dissolve the rice in the milk by boiling; reduce it to a

proper consistence, then add the spice and sugar, boil for 1 minute, and strain, and when nearly cold mould as above. *Caution.* The powdered rice must be rubbed up with a little cold water previously to adding it to the milk, to prevent it running into lumps.

VI. (*West Indian.*) Make a jelly with arrowroot, and to every pint, when nearly cold, add a glass of sherry, a spoonful each of brandy and orange flower water, and 2 oz. of lump sugar.

VII. (*Transparent.*) Instead of milk use water, and clarify with the white of an egg.

BLANQUENINE. A name given by Dr. Mills to a new vegetable alkali, which he thought he had discovered in white cinchona bark. (Quar. Jour. Science, Ap. 1828.)

BLANQUETTE, (IN COOKERY.) A sort of white fricasee.

BLEACHING. *Syn.* BLANCHISSAGE. (*Fr.*) BLEICHEN. (*Ger.*) The operation by which the natural colors of substances are discharged, and they become white or colorless. Bleaching may be performed either by natural means, as exposure to light, air, and moisture, or by chemical agents, as chlorine, chloride of lime, sulphurous acid, &c. In many of the processes adopted for this purpose, both methods are combined. The most important application of the art of bleaching in the United Kingdom, is in the manufacture of textile fabrics. The celerity with which this is performed in the most perfect manner, and the trifling expense thereby incurred, contribute, in no small degree, towards inducing that preference universally shown to the productions of the looms of Great Britain.

COTTON, from its original whiteness, and little attraction for coloring matter, is more easily bleached than most other substances. On the old plan, it is first well washed in warm water to remove the weaver's paste or dressing, then "*bucked*" (boiled) in a weak alkaline lye, and after being well washed is spread out upon the grass, or bleaching ground, and freely exposed to the joint action of light, air, and moisture. The operation of "*bucking*" and exposure is repeated as often as necessary, when the goods are "*soured*" or immersed in water acidulated with sulphuric acid, after which they receive a thorough washing in clean water, and are dried. From the length of the exposure upon the bleaching ground, this method has been found to injure the texture of the cloth, and from the number of operations required, necessarily becomes expensive, and produces considerable delay; it has therefore very generally given place to the improved system of chemical bleaching, by means of chloride of lime. In this method, after the first operation of washing and bucking, as in the common process, the cotton is submitted to the action of weak solutions of chloride of lime, and afterwards passed through soured water, when it has only to be thoroughly washed and dried.

LINEN is bleached in a similar way to cotton, but the operation is more troublesome, from its greater affinity for coloring matter.

WOOL is first exposed to the joint action of fuller's earth and soap, in the fulling mill, to remove adherent grease and dirt, and is then well washed and dried, when it is usually found sufficiently white for the purposes of the dyer; but should the slight yellow tint it retains prove objectionable, it is run through water tinged blue with indigo, or it is exposed to the fumes of burning sulphur; the latter method gives it a harsh feel, which is best removed by a bath of soap and water, but this will reproduce its previous yellowishness.

SILK is bleached by boiling it in white soap and water, to remove the natural yellow varnish that covers it, after which it is subjected to repeated rinsings. Articles that are required to be very white, as gloves, stockings, &c., are also submitted to the action of sulphurous acid, or the fumes of burning sulphur.

STRAW is also bleached by the fumes of sulphur; hence arises the sulphurous smell emitted by new straw hats and bonnets. They may, however, be bleached in a much better manner by the use of a little oxalic acid, or chloride of lime.

OLD RAGS, for the manufacture of paper, and paper pulp, are generally bleached with chlorine.

PRINTED BOOKS, ENGRAVINGS, &c., may be whitened by first subjecting them to the action of weak chloride of lime water, next to water soured with sulphuric acid, and, lastly, to pure water, to remove any adhering acid or chlorine.

Remarks. The theoretical principles of bleaching are but little understood; it is thought to depend upon the action of oxygen, in a nascent state, on the particles of coloring matter, but this is unsupported by direct experiment. It is, however, an art eminently indebted to chemistry for its present efficiency, and is based on the practical application of facts which that science has called to light.

BLEEDING FROM THE NOSE. When this occurs under common circumstances, and without violence, it may be regarded as a natural effort to relieve the body from an excess of blood; but when it becomes habitual, or is the result of violence, remedial measures should be had recourse to. A simple means of arresting the hæmorrhage is to introduce, by means of a probe, a small piece of lint or soft cotton, previously dipped into some mild styptic, as a solution of alum, white vitriol, or creosote, or even cold water. This will generally succeed, but should it not, cold water may be snuffed up the nostrils, or a small piece of ice placed in the nose. Should the bleeding be very profuse, or persistent, medical advice should be had recourse to. I once saw a person (an innkeeper) lose his life in the course of a few days from a voluntary hæmorrhage from the nose, which it was found impossible to stop or lessen.

A plan has been lately proposed by Dr. Negrier, of Angiers, which, he says, is simple and certain. "It is preferable to the occlusion of the nostrils, as that is difficult to maintain, especially in sleep. During three years that, in numerous cases, he has tried this method, which is simply elevating the patient's arm, he has never found it to fail. After detailing several cases, he thus explains the rationale of the plan. When the person is standing with the arms at the side, the blood which escapes from the upper part of the arch of the aorta, takes two directions, viz., towards the head, and towards the arms, and that which goes to the head is almost equal in quantity to that which is received by both superior extremities. If, however, the individual who was formerly hanging his arms, raised them, the blood which was flowing horizon-

tally and without effort from the subclavian into the brachial arteries, must then ascend against the weight of the column of blood contained in the latter; and as there is nothing in the act of raising the arm to increase the force of the circulation, it follows, that part of the force formerly expended in sending the blood up the carotids, must now be subtracted, and added to that which drives it through the brachial arteries. This explanation may or may not be confirmed by experiments. The subject is worth investigation." (Archives générales de Médecine. June, 1842.)

BLENORRHŒA. An increased discharge of mucus from the urethra or vagina. *Treat.* Administer mild aperients and tonics. Cold bathing, and general habits of cleanliness, powerfully promote a cure.

BLIND, WRITING FOR THE. If an iron style or pencil, with a moderately fine point, be used to write with upon paper, and a little more pressure be employed than in using a common pen, characters will be produced which may easily be read by blind persons after a little practice, by passing their fingers over them, either on the side on which they were written, where they will appear in intaglio, or by reversing the paper, where they will appear in relief.

BLISTER, EXTEMPORANEOUS. I. A piece of lint dipped into vinegar of cantharides, and immediately after its application to the skin, covered over with a piece of strapping, to prevent evaporation, will speedily raise a blister.

II. Concentrated acetic acid, applied in the same way, will have a similar effect.

III. The following method, proposed by Dr. Darcq, is very simple and convenient: Into a flat watch-glass, pour from 8 to 10 drops of very concentrated ammonia; cover the liquid with a small piece of linen, of a rather less diameter than that of the glass, and slowly apply this little apparatus to the previously shaved skin. Keep the whole in its place by means of moderate pressure with the fingers.

As soon as a red ring, about 2 *centimetres* in breadth, is observed round the glass, it is certain that vesication is effected. Sometimes scarcely 30 seconds is necessary for obtaining this result. It remains only to remove the apparatus, to wash the part, and to tear away with a pair of nippers the epidermis, which comes off easily and in one piece.

The dressing is according to the object in view,—to the indications of the endermic method, for example. (Bull. de Thér. & Chem., No. L. 88.)

BLISTER, LIQUID. *Prep.* I. Spanish flies 2 oz.; boiling water 1 pint; spirits of wine 4 oz.; corrosive sublimate ¼ oz.; spirits of salts ½ oz. *Proc.* Digest the flies in the water, in a warm place, for 24 hours, then add the corrosive sublimate, dissolved in the spirits of wine, and lastly, the spirits of salts. It may either be strained, or used as it is.

II. Rectified spirit, and liquid ammonia, of each 2 oz.; oil of origanum 1 oz.; mix. Add finely powdered Spanish flies 1 oz.

III. Strongest blistering plaster 2 oz.; oil of turpentine 1 oz.; mix with a gentle heat.

IV. Linseed oil, resin cerate, and oil of turpentine, of each 2½ oz.; powdered flies 1 oz.; as above. *Use.* For horses and cattle.

BLISTER, PERPETUAL. A common blister, raised in the usual way, but instead of allowing the surface to heal up, after the discharge of the water, it is kept open by dressing it with savine or cantharides ointment.

BLISTERING TISSUE. Thin paper, or silk, spread over with a thin coat of alcoholic, acetic, or ethereal extract of Spanish flies.

BLOOD, BULLOCK'S. This article is employed for the clarification of wines and sirups; in the preparation of adhesive cements; coarse paint for out-door work; as a manure; as a bleaching powder; and for several other purposes. The blood of sheep, pigs, and bullocks, mixed with flour or oatmeal, and seasoning, is used as an aliment by the common people, but it is rather indigestible, and consequently cannot prove nourishing.

BLOOD, POWDERED. *Prep.* Dry the blood, by free exposure in thin layers to a current of air, at a heat under 125°, until it becomes sufficiently dry to powder. *Use.* For exportation to the colonies, where it is used in the sugar works. *Remarks.* Bullock's blood, dried at a temperature from 212° to 225°, and coarsely powdered, is much used by fraudulent dealers to adulterate musk.

BLOOD, SPITTING OF. (See Hæmoptysis.)

BLOOD, SPITTING OF. Popular Remedy for. *Prep.* Infusion of red roses 5½ oz.; sirup of poppies ½ oz.; diluted sulphuric acid 20 drops; mix. *Dose.* One or two tablespoonfuls four times a day.

BLOOM, ALMOND. *Prep.* Boil 1 oz. of ground Brazil wood in 3 pints of water, for 15 minutes, strain and add ¾ oz. of isinglass, ¼ oz. of powdered cochineal, 1 oz. of alum, and ½ oz. of borax; boil again for 3 minutes, or until the whole is dissolved, and strain through a piece of fine cloth.

BLOWPIPE. An instrument by means of which the flame of a candle or lamp is directed upon any substance placed to receive it, which is thus subjected to an intense heat.

The hottest portion of the flame produced by the action of the blowpipe, is at the tip of the outer white flame, which has also the property of rapidly burning or oxidizing any substance placed in it, which is capable of such an action; hence it has been called the "*oxidizing flame.*" The interior blue flame has also been called the "*reducing flame,*" from the property it possesses of abstracting oxygen from most substances placed in it.

App. "The substance to be submitted to the action of the blowpipe, must be placed on a piece of charcoal, or in a small spoon of platina, gold, or silver; or, according to Saussure, a plate of cyanite may sometimes be used. Charcoal from the pine is to be preferred, which should be well ignited and dried, that it may not crack. The sides, not the ends, of the fibres must be used; otherwise the substance to be fused spreads about, and a round bead will not be formed. A small hole is to be made in the charcoal, which is best done by a slip of plate iron bent longitudinally. Into this hole the substance to be examined must be put, in very small quantity; if a very intense heat is to be used, it should not exceed the size of half a peppercorn.

"Metallic spoons are used when the substance to be examined is intended to be exposed to the action of heat only, and might undergo some change by immediate contact with the charcoal. When the spoon is used, the flame of the blowpipe should be directed to that part of it which contains the substance under examination, and not be immediately applied to the substance itself. The handle of the spoon may be inserted into a piece of charcoal; and if a very intense heat is required, the bowl of the spoon may be adapted to a hole in the charcoal. Small portions may be taken up by platina forceps. Salts and volatile substances are to be heated in a glass tube closed at one end, and enlarged according to circumstances, so as to form a small matrass."

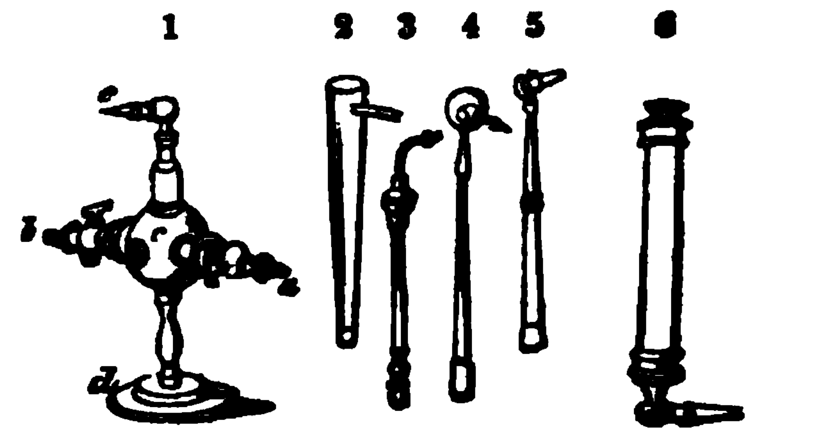
When the behavior of the substance has been observed in this way, it is melted with various fluxes, as microcosmic salt, borax, &c., and their action examined, both in the interior and exterior flame, by which means its composition may be generally ascertained, by reference to any work on mineralogy.

Beginners are usually unable to maintain a continual stream of air from the jet, which is, however, very simple to accomplish. The operation depends upon a little artifice in blowing through the pipe, which is in reality more difficult to describe than to acquire. "The effect intended to be produced is a continual stream of air for many minutes, if necessary, without ceasing. This is done by applying the tongue to the roof of the mouth, so as to interrupt the communication between the mouth and the passage of the nostrils; by which means the operator is at liberty to breathe through the nostrils, at the same time that by the muscles of the lips he forces a continual stream of air from the anterior part of the mouth through the blowpipe. When the mouth begins to be empty, it is replenished by the lungs in an instant, while the tongue is withdrawn from the roof of the mouth, and replaced again in the same manner as in pronouncing the monosyllable *tut*. In this way, the stream may be continued for a long time without any fatigue, if the flame be not urged too impetuously; and even in this case no other fatigue is felt than that of the muscles of the lips." (Ure.)

For producing extreme degrees of heat, the flame is blown with a jet of oxygen gas, and the instrument is then called an "*oxygen blowpipe;*" or a mixture of oxygen and hydrogen is burned, when it is called an "*oxy-hydrogen*" blowpipe. The heat produced by the last is so great that no substance can stand before it. The most refractory native compounds, as rock crystal, quartz, flint, chalk, plumbago, &c., are immediately fused. Gold is volatilized, and iron is rapidly consumed the instant it is placed in the flame. To use this wonderful instrument with safety, and to prevent an explosion, a peculiarly constructed jet is required. The principal blowpipes in general use are figured in the accompanying engravings. The shape of the common blowpipe adopted by the experimentalist may depend upon the fancy of its employer.

This apparatus is also furnished with valves and springs.

Beside the following there are several other va-



1, Oxy-hydrogen blowpipe.
2, Black's do.
3, Bergman's do.
4, Pepy's do.
5, Wollaston's do.
6, Hemming's safety jet for the oxy-hydrogen ditto.

a, Pipe conveying oxygen gas.
b, Do. do. hydrogen gas.
c, Ball stuffed with fine wire gauze.
e, Jet, (internal diameter 1-80th of an inch.)

rieties of blowpipes, in which the air is expelled by the pressure of a column of water, (hence called "*hydrostatic blowpipes,*") or the flame blown with the vapor of boiling alcohol, ("*spirit blowpipe.*")

Use. The blowpipe is of most extensive application in qualitative analysis, especially of minerals, and its use cannot be too highly recommended to the young chemist.

For further information on this subject the reader is referred to Gahn on the Blowpipe; to Ure's Dictionary of Chemistry; to Campbell's Translation of Kobell's Instructions for the Discrimination of Minerals; and to the Chemist, iv. 462.

BLUBBER. This substance, which is so plentiful on some parts of the coast of England, forms a very rich manure for pasture and arable land, when used at the rate of 1 ton to every 20 or 30 loads of mould, together with a chaldron of lime per acre. It must be well turned over, and after lying 3 or 4 months the land will be in prime condition.

BLUE, CHARCOAL. *Prep.* Triturate carbonized vine stalks with an equal weight of potash, then put it into a crucible and place it over the fire, until the mixture ceases to swell, keeping it well stirred all the time; next allow it to cool, dissolve it in water, and saturate the excess of alkali with dilute sulphuric acid; the liquid becomes blue, and a dark precipitate falls down, which turns of a brilliant blue color when dried and heated.

BLUE, COBALT. *Prep.* I. Dissolve Zaffre 1 lb. in ¾ lb. of nitric acid, diluted with an equal weight of water, by digestion for some hours, evaporate nearly to dryness, then dissolve in warm water, filter and add a solution of phosphate of soda as long as any precipitate falls down; collect this on a filter and wash it with cold water, then mix it while still moist with 8 times its weight of freshly precipitate hydrate of alumina, also well washed and still moist. Stir them together until dry; lastly, expose the mixture to a cherry red heat in a crucible, after which cool the mass, and reduce it to a fine powder.

II. Precipitate a solution of nitrate of cobalt as above, and proceed as before.

III. Make a strong solution of neutral nitrate

of cobalt, and mix it with pure moist alumina, then dry it and proceed as before.

IV. Precipitate a solution of nitrate of cobalt with ammonia alum, collect the precipitate, wash, dry, and heat it to a cherry red as before.

Use. A beautiful blue pigment, very permanent.

BLUE, CHEMIC. *Syn.* SAXON BLUE. LIQUID BLUE. SULPHATE OF INDIGO. *Prep.* I. Indigo 1 lb.; oil of vitriol 8 lbs. *Proc.* Put the acid into an earthenware pan, placed in a tub of water to keep it cool, and add the indigo, previously reduced to fine powder, in small successive portions, carefully stirring to prevent it *heating*. When all the indigo has been added, cover up the vessel and let it stand for 4 hours, occasionally stirring it during the time; lastly, dilute it with an equal weight of water.

II. Indigo 1 oz.; oil of vitriol 4 oz.; dissolve as before; the next day add 1 oz. of dry potash; let it stand a day longer, then dilute it with 12 oz. of water.

Use. In dyeing greens and blues, either without preparation or with a mordant of alum and tartar.

BLUE, CHINA. *Syn.* ROYAL SMALTS. *Prep.* Grind together oxide of cobalt or zaffre, with an equal weight of potash, and 8 times its weight of feldspar. Then submit the mixture to fusion in a crucible. *Use.* To paint pottery, and as a pigment.

BLUE, IRON. *Prep.* Precipitate a filtered solution of protosulphate of iron, with another of phosphate of soda. Collect the powder, wash and dry it. *Use.* A lively sky-blue.

BLUE, MOLYBDENUM. *Prep.* Dissolve sulphuret of molybdenum in nitric acid, then add some tin filings and a little muriatic acid. After digestion for some time, pour off the clear and evaporate to dryness. Mix the powder thus obtained with moist hydrate of alumina, as in making cobalt blue, and heat it to nearly a dull red.

BLUE, MOUNTAIN. Carbonate of copper, mixed with earthy matter.

BLUE, SAXON. *Prep.* Dissolve 1 oz. of sulphate of iron and 8 oz. of alum in 1 gallon of water, then add simultaneously, separate solutions of prussiate of potash and common pearlash, until they cease to produce a precipitate; lastly, allow the liquid to deposite, decant the clear portion, wash the remainder well with water, and dry it. Or a solution of the sulphate of iron may be first made and precipitated with the prussiate of potash, and instantly mixed with the solution of alum and a solution of pearlash, added until it ceases to produce a precipitate.

BLUE, SUPERB LIQUID. *Prep.* Put into a small matrass or common vial 1 oz. of pure Prussian blue reduced to powder, and pour over it from 1½ oz. to 2 oz. of concentrated mur'atic acid. The mixture produces an effervescence and the prussiate soon assumes the consistence of thin paste. Leave it in this state for 24 hours, then dilute it with 8 or 9 oz. of water, and preserve the color thus diluted in a bottle well stopped.

The intensity of this color may be lessened, if necessary, by new doses of water. If the whole of this mixture be poured into 1 quart of water, it will still exhibit a color sufficiently dark for washing prints.

BLUE, STONE. *Syn.* FIG BLUE. THUMB BLUE. KNOB BLUE. CROWN BLUE. MECKLENBURG BLUE. QUEEN'S BLUE. *Prep.* Mix finely powdered indigo with starch paste until a proper color be produced, then make it into small lumps. II. Instead of starch use whiting and a little weak size. *Use.* Employed by laundresses to give a faint blue tinge to linen.

BLUE DYE. *Proc.* First give the goods a mordant of alum, then rinse them well and boil them in a bath of logwood, to which a small quantity of blue vitriol has been added.

II. Boil in a bath of logwood, then add 1 oz. each of tartar and verdigris to every pound of logwood employed, and boil again.

III. Bilberries, elder-berries, mulberries, privet-berries, and several other vegetable blue substances, may be used to dye blue as above instead of logwood.

Remarks. By increasing the proportion of alum the color verges on purple, and by employing a little acetate of iron or green copperas, the darker shades are produced. Verdigris, blue vitriol, and alkalis turn it more on the blue, and a mordant of tin imparts a violet cast. None of these dyes, however skilfully managed, are so permanent as those produced with indigo and Prussian blue. (See INDIGO, PRUSSIAN BLUE, and DYEING.)

BOARDS, MARBLE, &c., TO TAKE OIL AND GREASE OUT OF. I. Make a paste with fuller's earth and hot water, cover the spots therewith, let it dry on, and the next day scour it off with soft or yellow soap.

II. Make a paste with soft soap, fuller's earth, and a little pearlash, and use it as above.

III. Make a paste of fresh slaked lime, water, and pearlash, and use it as above. *Remarks.* Observe not to touch the last mixture with the finger, as it is very caustic unless it be largely diluted with water.

BOERHAAVE'S RULES FOR PRESERVING HEALTH.

"Keep the feet warm;
The head cool; and
The body open."

These rules are very concise, and convey directions which, though valuable, are too often neglected.

BOILING POINT. The boiling point of water may be raised considerably above 212° Fahr. by the addition of saline matter. Thus, 60 parts of dry acetate of soda added to 40 of water raise the boiling point to 256° Fahr., and 30 parts of muriate of soda added to 70 of water raise it to 224 Fahr. As in practice, however, it proves inconvenient to employ a saturated solution for a bath, from the evaporation of the water continually inducing the salt to crystallize, it is usual to keep it considerably below that point. By means of such solutions the chemist is enabled to evaporate fluids and desiccate solids at any required temperature. The boiling point of baths containing different salts may be seen below.

TABLE of the Boiling Points of several Saline Solutions, abridged from the Table of Mr. T. GRIFFITHS. (Jour. Science, xviii. 89.)

Names of Salts.	Dry Salt in 100.	Boiling Point.
Acetate of soda, . . .	60	256° F.
Nitrate of soda, . . .	60	246
Rochelle salt, ...	90	240
Nitre, ...	74	238
Muriate of ammonia, .	50	236
Tartrate of potash, . .	68	234
Muriate of soda, . . .	30	224
Ditto, ...	20	218·75
Muriate of lime, . . .	40	216·5
Sulphate of magnesia, .	57·5	222
Supersulphate of potash,	?	222
Borax, ...	52·5	222
Phosphate of soda, . .	?	222
Carbonate of soda, . .	?	220
Muriate of baryta, . .	45	220
Alum, ...	52	220
Sulphate of potash, . .	17·5	215
Bitartrate of potash, .	9·5	214
Sulphate of soda, . .	31·5	213

Remarks. From 5 to 9 degrees are usually lost by passing through the vessel, depending on its thickness and materials. The boiling point of water in glass vessels, under common circumstances, varies from 212·54° to 215·6°, and in perfectly pure and smooth glass vessels, water may be heated to 221° F. without boiling. (M. F. Marcet.)

BOILS. *Treat.* When these appear, suppuration should be promoted by poultices of bread and linseed meal, to which a little fat or oil may be added, to prevent their getting hard. When poultices are inconvenient, exposure to the vapor of hot water, or the application of stimulating plasters, may be adopted instead. When sufficiently ripe, the matter should be evacuated, and the wound dressed with a little simple ointment spread on a piece of clean lint or linen. The diet may be full and liberal until the maturation of the tumor and the discharge of the matter, when it should be lessened, and the bowels opened by some saline purgatives, as salts or cream of tartar. When there is a disposition in the constitution to the formation of boils, the bowels should be kept regular, and tonics, as bark or steel, taken, with the frequent use of sea-bathing, if possible.

BOLAS. *Prep.* Into 2 lbs. of flour pour ¾ pint of warm milk, a small teacupful of yeast, and 6 eggs; make them into a dough, add 1 lb. of butter, by degrees, and let it rise for 1 hour, then mix in 1 lb. of powdered sugar, and make the mass into cakes; put these into cups or tins previously well buttered, and ornament the top with candied orange or lemon peel; lastly, bake them.

BOLUS OF ALUM. *Prep.* Powdered alum and conserve roses, of each 15 grs.; sirup of orange peel or saffron to mix. *Used* in fluxes, &c.

BOLUS OF MUSK. *Prep.* I. Musk 15 grs.; camphor 5 grs.; powdered gum 3 grs.; mix with sirup of saffron. *Use.* In convulsions and typhus fever.

II. Musk and carbonate of ammonia of each 10 grs.; conserve of roses q. s.; to make a bolus. *Use.* Sometimes given every three hours in mortification accompanied with spasms.

BOLUS, PURGING, (FOR DOGS.) *Prep.* Jalap and rhubarb, of each 15 grs.; ginger 4 grs.; soap 10 grs.; water q. s.; if this does not open the bowels, add aloes half a drachm, or 3 or 4 grs. of calomel. *Use.* In the distemper; it must be preceded by copious bleeding, and abstinence from food for a day or a night.

BOLUS OF SULPHATE OF ZINC. *Prep.* Sulphate of zinc 20 to 25 grs.; conserve of roses q. s. to make a bolus. *Use.* As an emetic where poison has been taken, to be followed by copious draughts of warm water or weak tea.

BOLETIC ACID. An acid discovered by Braconnot in the juice of the boletus pseudo-igniarius.

Prep. Concentrate the expressed juice to a sirup by means of a gentle heat, then digest it in strong alcohol, and dissolve the residuum in water; add a solution of nitrate of lead as long as any precipitate falls, which must be washed with water, diffused through water in a tall glass vessel, and in this state a current of sulphureted hydrogen must be passed through it, until the lead is thrown down; filter, evaporate, and crystallize; lastly, purify by resolution and crystallization from alcohol.

Remarks. This acid dissolves in 45 parts of alcohol and 180 of water, and is volatile. It is doubtful whether it be a distinct acid principle.

BOLOGNA VIAL. The bologna, or philosophical vial, is a small vessel of glass which has been suddenly cooled, open at the upper end, and rounded at the bottom. It is made so thick at the bottom that it will bear a smart blow against a hard body without breaking; but if a little pebble, or piece of flint, is let fall into it, it immediately cracks, and the bottom falls into pieces; but unless the pebble or flint is large and angular enough to scratch the surface of the glass, it will not break.

BOLOGNIAN PHOSPHORUS. *Syn.* BOLOGNIAN STONE. This is a phosphorescent stone that once excited great attention. It was accidentally discovered by a shoemaker of Bologna in the 17th century. A family of the name of Logani, who were very successful in making it, acquired a large fortune by selling it to the curious throughout Europe.

Prep. Powder native sulphate of baryta that has been previously ignited, and make it into a paste with mucilage of gum arabic; roll this into pieces a quarter of an inch thick, and dry them in a moderate heat; then expose them to the heat of a wind furnace by placing them loose among the charcoal.

Prop., Use, &c. Placed in a vial and exposed for a few minutes to the sun's rays, it will give light enough in the dark to see the figures on the dial-plate of a watch.

BOMBIC ACID. An acid which M. Chaussier extracted from the silkworm in 1781. It has since been found not to be a distinct acid.

BON-BONS. *Prep.* Provide leaden moulds, which must be of various shapes, and be oiled with oil of sweet almonds. Take a quantity of brown-sugar sirup in the proportion to their size, in that state called a *blow,* which may be known by dipping the skimmer into the sugar, shaking it, and

blowing through the holes, when parts of light may be seen; add a drop of any esteemed essence. If the *bon-bons* are preferred white, when the sugar has cooled a little, stir it round the pan till it grains, and shines on the surface; then pour it into a funnel and fill the little moulds, when it will take a proper form and harden: as soon as it is cold take it from the moulds; dry it for two or three days, and put it upon paper. If the *bon-bons* are required to be colored, add the color just as the sugar is ready to be taken off the fire.

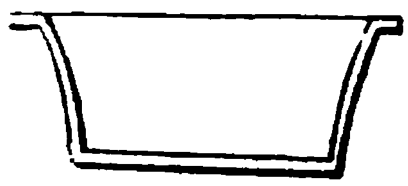
BONES. The bones of animals are employed for various purposes in the arts, manufactures, and domestic economy. (See the succeeding articles.)

BONE ASH. *Syn.* Impure Phosphate of Lime. *Prep.* Calcine bones to whiteness, and reduce the ash to fine powder. *Use.* To make pure phosphate of lime, and to form cupels. It is sold for burnt hartshorn.

BONE BLACK. *Syn.* Animal Charcoal. Ivory-Black. Bones burnt in close vessels.

Prep. On the large scale, two different processes are adopted to produce bone black.

I. (*From bones as the sole product.*) The bones broken to pieces are put into small cast-iron pots of the shape of the engraving, and varying from



⅜ to ½ an inch in thickness. Two of these being filled, are dexterously placed with their mouths together and then luted with loam. A number of vessels, thus prepared, are placed side by side and over each other, in an oven resembling a potter's kiln, to the number of 100 to 150. The fire is then kindled, and the heat kept up strongly for 10 or 12 hours, according to circumstances, until the process is completed. The whole is allowed to cool before opening the pots.

II. (*The residuum of the manufacture of Bone Spirit.*) The bones are here introduced into retorts similar to those used at the gas works, and heat being applied, the volatile products are conveyed away by iron pipes to cisterns where its condensable portion is collected. As soon as the process of distillation is finished, the solid residuum in the retorts, while still red hot, is removed through their lower ends into wrought-iron canisters, which are instantly closed by air-tight covers, and luted over. These are then raised to the ground by a crane and allowed to cool.

Remarks. Previously to distillation or calcination, the bones are boiled for their grease, which is sold to the candle and soap makers. They are then sorted, the finest pieces being selected for making handles for knives, tooth-brushes, buttons, &c.; the next sort for making into bone black; while the smallest and worst description is reserved for grinding into manure. The bones lose about ½ their weight by the process of burning. After this they are ground in a mill, sorted by sieves into two kinds, one *granular*, somewhat resembling gunpowder, and the other *quite fine.* The one is sold under the name of *animal charcoal*, for decoloring liquors, the other as a *pigment*. This article possesses the valuable property of taking lime from sirups, at the same time that it decolors them. Its power as a decolorizer may be tested by adding it to a solution of brown sugar or molasses, or water containing $\frac{1}{1000}$ part of indigo dissolved in sulphuric acid. The test should be made in a small glass tube. By well washing and careful reburning, this charcoal may be used any number of times as a decolorizer.

BONES AND IVORY, DYES FOR. 1. (*Red.*) *a.* Make an infusion of cochineal in water of ammonia, then immerse the pieces therein, having previously soaked them for a few minutes in very weak aquafortis and water.

b. Boil the bones with 1 lb. of Brazil dust, in 1 gallon of water, for 3 hours, then add ¼ lb. of alum and boil for 1 hour more.

2. (*Black.*) *a.* Immerse the pieces in a weak solution of nitrate of silver, for a short time, then expose them to the sunlight.

b. Steep for 2 or 3 days, in a decoction made with 1 lb. of galls and 2 lbs. of logwood, then steep for a few hours in iron liquor, (acetate of iron.)

3. (*Green.*) *a.* Steep in a solution of verdigris to which a little aquafortis has been added.

b. Dissolve distilled verdigris in weak vinegar, and steep the pieces therein.

c. Steep in a solution of 2 parts of verdigris, and 1 of sal ammoniac. *Observe* not to use a metallic vessel for the above.

4. (*Purple.*) *a.* Steep in a weak solution of terchloride of gold.

b. Boil for 6 hours in a decoction of 1 lb. of logwood in ½ gallon of water, adding more water, as it wastes by boiling, then add 2 oz. of alum, and boil for 1 hour more.

5. (*Yellow.*) *a.* Boil for 1 hour in a solution made with 1 pound of alum in 1 gallon of water, then take out the pieces and steep them in a decoction made with ½ lb. of turmeric in 2 quarts of water; lastly, mix the two liquors and boil them therein for 1 hour.

b. Steep the pieces for 24 hours in a solution of sugar of lead, then take them out, and when dry, immerse them in a solution of chromate of potassa.

c. Dissolve as much of the best orpiment in water of ammonia or hartshorn, as it will take up, then steep the pieces therein for twenty-four hours; lastly, take them out and dry them, when they will turn yellow. *Remark.* By diluting the solution with water, any shade of yellow may be made.

6. (*Blue.*) *a.* Stain them green, then steep them in a hot and strong solution of pearlash.

b. Boil them in a strong decoction of logwood, and afterwards steep them in a solution of blue vitriol.

c. Steep them for a short time in a weak solution of sulphate of indigo, to which a little salt of tartar has been added; or, still better, boil them in a dyer's green indigo vat. *Remarks.* The bones of living animals may be dyed by mixing madder with their food. The bones of young pigeons may thus be tinged of a rose color in 24 hours, and of a deep scarlet in 3 days; but the bones of adult animals take a fortnight to acquire a rose color. The bones nearest the heart become tinged soonest. In the same way extract of logwood will tinge the bones of young pigeons purple. (Mr. Gibson.)

BONE GREASE. *Prep.* By bruising and boiling the refuse bones of the kitchen, and skimming the broth when cold, from ¼ (?) to ⅓ of their

weight of good fat may be obtained, fit for culinary purposes when fresh, but always excellent for making soap and candles. (Proust.)

BONE GLUE. *Syn.* Gelatine. *Prep.* This is made by dissolving out the earth of bones, previously boiled for the grease, washing the remaining jelly with water, then boiling it with a little water, and forming it into cakes for sale. (See Glue.)

BONE MANURE. For this purpose the bones are ground to a coarse powder in a mill, and sowed along with the seed in a drill. It is said that wheat thus treated yields 30 to 50 per cent. more in weight of straw and grain than by the common methods. It is usually applied to light or turnip soils, which it renders more than ordinarily productive. Bone manure is much used in the west of Yorkshire, Holderness, and Lincolnshire. The usual quantity per acre is 70 bushels, when used alone; but when mixed with ashes, as common manure of any sort, 30 bushels per acre is thought quite enough. It is applied at the same periods as other manure, and has been found in this way to remain 7 years in the ground. The rough part of this manure, after being 5 years in the ground, has been gathered off one field and thrown upon another of a different soil, and has proved, even then, good manure.

BONES, (in Cookery.) The bones of good meat form most excellent materials for making soups and gravies, as is well known to every good cook. In France, soup is extensively made by dissolving bruised bones in a steam heat of 2 or 3 days' continuance, and also by dissolving out the earthy part by digestion in weak muriatic acid, when a lump of gelatine is obtained, which after being well washed with water will dissolve by boiling, and is equal to isinglass for all the purposes of making soups and jellies. Proust has recommended the following process for making the best of bones, in hospitals, jails, and similar establishments:—Crush the bones small, then boil them for 15 minutes in a kettle of water, cool, and skim the fat off, which varies from $\frac{1}{8}$ to $\frac{1}{4}$ (?) of the weight of the bones employed, and when fresh is fit for all common purposes. The bones are then ground, and boiled in 8 to 10 times their weight of water, of which that already used must form a part, until $\frac{1}{8}$ is wasted, when a very nutritious jelly is obtained. A copper vessel should not be used, as the jelly acts upon this metal. An iron Papin's digester is the most suitable. The bones of boiled meat are nearly as productive as those of fresh meat, but roasted meat bones scarcely afford any jelly. (Dr. Young.) As boning meat before cooking is now a very general practice, a quantity of fresh bones may always be had.

BONE SHAVINGS. *Syn.* Bone Dust. Bone Turnings. These yield a beautiful jelly by boiling with water, nearly equal to that produced from hartshorn shavings, for which they are very frequently sold.

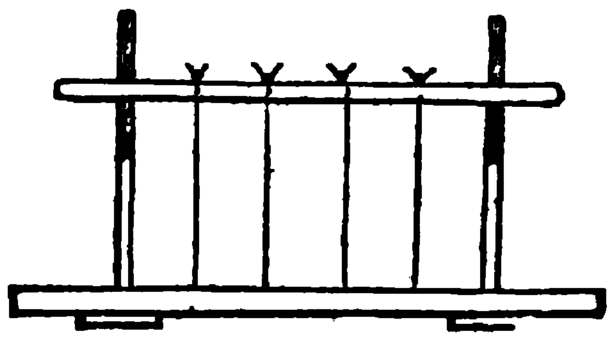
BOOKBINDING. The process of binding books may be divided into several distinct operations, which, in large establishments, are usually performed by different persons, such a method being found to produce greater expedition and better work, than when the whole is done by one person.

The sheets received from the hands of the printer are—

1. *Folded*, which is done correctly by observing the marks or catchwords at the bottom of the pages. As the sheets are folded they are laid upon each other in proper order, and are ready to undergo—

2. *The operation of beating.* This is performed by laying them upon a large stone, and striking them with a heavy smoothed-faced hammer, or by passing them through a rolling press. The former method is usually adopted in the small way, and the latter on the large scale.

3. *The sheets are next fastened to bands*, which is done by taking the folded sheets up one by one, and sewing them to pieces of cord, stretched in a little frame screwed or fastened to the counter or table, called the sewing-press. (See eng.) The



number of bands used, is generally 6 for a folio, 5 for a quarto, and so on proportionally, less than 4 seldom being employed even for small sizes. The ends of the cords being cut off to within about 2 inches of the back, the sheets are ready for—

4. *Glueing.* The back being knocked into shape with a hammer, and the sheets placed in the cutting press, which is then slightly screwed up, melted glue is thinly and evenly applied. After a short time the book is removed from the press, and the back properly adjusted with a hammer, when it is again put into the cutting press, where it is screwed up very tight, and is then ready for—

5. *Cutting.* The instrument employed for this purpose is of a peculiar shape, and called a plough or plough-knife.

6. *Affixing the boards. The bands*, are now scraped out fine at the ends, and the pasteboard to form the covers is fastened thereto, and is then properly adjusted, and shaped with a large pair of shears. The edges now undergo the operation of—

7. *Sprinkling*, or other adornment. The first is performed by a stiff brush of hog's bristles, dipped in the color; the brush being held in the one hand, and the hairs moved with the other.

8. *The external covering of leather, fancy cloth, or paper*, is now applied, having been previously well soaked in paste, to make it properly adhere. One or more of the blank leaves of the book are next pasted against the inside of the cover, to screen the ends that are turned over, when the book is finished; or for choice work, is handed to a "*finisher*" for—

9. *Lettering, gilding, &c.* Gold-leaf is applied by means of white of egg, the pattern being given by pressure with heated brass tools, having the design or letters on their surfaces. The whole is then glazed over and polished.

Remarks. The succession of some of the above operations sometimes varies with the workmen and

the nature of the binding. The above must therefore only be regarded as a short and general outline of the process. If the reader will accompany the perusal by an examination of a bound book, the whole will be rendered quite familiar.

The following varieties of binding may be noticed:

a. Boards. A book, loosely done up without cutting the edges, and covered with paper or cloth, is said to be in boards.

b. Cloth-binding. This style of binding is that in which the majority of works are now issued. It admits of great neatness and even beauty, and is very durable and cheap. *Proc.* The prepared cloth, cut by a pattern to the size suited to the volume, is passed rapidly through a rolling press, between engraved cylinders of hardened steel, which print the pattern in relief. Paste is now applied to the cloth, when it is placed over the volume, previously prepared to receive it. Books in cloth-binding are not commonly cut at the edges, unless highly finished.

c. Dutch binding. This species of binding is distinguished by the backs being of vellum.

d. French binding. This consists in pasting a piece of parchment over the back of the book, between each band, and pasting the ends upon the inside of each cover.

e. Half-binding. Books forwarded in boards, and finished with leather backs and corners, are called "*half-bound.*"

f. Hancock's patent binding. In this method the sheets are folded in double leaves, and being properly placed together and adjusted, the book is subjected to the action of a press, and a strong solution of Indian rubber is smeared over the back with the finger. The operation is repeated, as often as necessary, when fillets of cloth are cemented on with the varnish, and the book is ready to have the boards attached. Thus several of the common operations of binding are dispensed with. I willingly bear testimony to the strength and durability of this method, and the great convenience it affords in allowing the books to open perfectly flat upon a table, or to be distorted in any possible manner, without injury to their backs. It is the best way of binding books for travellers. I once had a large trunk of books, among which was one bound on Hancock's plan. All the rest were nearly torn to pieces by a few months' journey, but this one was uninjured.

g. Law binding. A strong method applied to law books.

h. Leather binding. *Proc.* Immerse the leather in water; after which wring it, and stretch it on a board; place the book with the boards extended thereon, and cut out the cover, allowing about half an inch larger than the book, to turn over the inside of the pasteboards. Pare the edges of the cover very thin all round on a marble slab, and paste it well; glue the back of the book, and spread the cover on the board.

Let the pasteboards be properly squared and even; put the book on the cover, which draw on very tight. Rub the cover smooth with a folding-stick, and turn it over on the inside of the pasteboards on the fore edge. The corners on the inside must be cut and neatly pressed down; tie a piece of thread round the book, between the boards and head-bands, draw up the leather on the back, if necessary, to cover the top of the head-bands; rub the back very smooth with a flat folding-stick, and place it at a distance from the fire to dry.

Rough calf must be damped on the grain side with a sponge and water before pasting and covering.

Russia leather must be well soaked in water fo an hour, taken out, well beaten, and rubbed; afte which the paste must be well worked into the flesl side before covering.

Morocco must be grained by rubbing it on a board, with the grain side inside, and after being pasted, left to soak for a quarter of an hour, and the cover then drawn on with a piece of woollen cloth to preserve the grain.

Roan may be either soaked in water or left to soak when pasted.

i. Italian binding. This is a common variety of binding employed in Italy, (hence its name,) in which the books are covered with a kind of thick coarse paper. In Italy it is called "*alla rustica.*"

k. Marble binding. Named from the design of the exterior.

l. Palmer's patent binding. This consists in applying small brass bars, linked together, to the back of the book, in such a manner that they make the different sections of the book, when open, parallel with each other, and thus admit of writing, without inconvenience, on the ruled lines near the back.

m. School binding. The following is a strong method for school books:—When the books have been cut, colored, and backed, cut off the part of the bands intended to be laced to the pasteboards, and glue on the back a piece of strong smooth linen cloth, which must reach within half an inch of the head and foot, turning on the sides about an inch; paste the boards on each side of the cloth, fixing them close in at the groove, and give the books a firm pressing in the standing-press till dry. Square the boards, glue the backs, and cover and finish in the usual manner.

This method will secure and give strength to the joints, so as effectually to prevent the leather from breaking, and require no more time than lacing in the bands. The edges may now be colored, sprinkled, or marbled, as required.

n. William's patent binding. This consists in placing a back, of a curved form, turned a little at the edges, and made of iron, copper, brass, wood, ivory, or any other material of sufficient firmness. This back is adjusted to the book before it is bound, in such a manner that it may just cover, but not press upon the edges, and is fastened on by enclosing it in vellum or ferret wrappers, which are pasted down upon the boards or drawn through them. The effect is, to make the book open evenly and freely, and to prevent it from spreading on either side.

BOOTS, TO CLEAN. To do this in the best style always use "boot-trees," employ but little blacking, and brush it off while damp. The dirt should, of course, be carefully brushed off before applying the blacking.

BOOTS AND SHOES, WATERPROOF COMPOSITION FOR. *Prep.* Boiled oil 1 pint; oil of turpentine, black rosin, and bees' wax, of each 3 oz. *Proc.* Melt the wax and rosin, then stir in the oil, remove the pot from the fire, and when it has cooled a little, add the turpentine.

II. Take 3 oz. of spermaceti, and melt it in a pipkin, or other earthen vessel, over a slow fire; add thereto 6 drachms of Indian rubber, cut into slices, and these will presently dissolve. Then add *seriatim* of tallow 8 oz.; hog's lard 2 oz.; amber varnish 4 oz. Mix, and it will be fit for use immediately. *App.* The boots or other material to be treated, are to receive two or three coats, with a common bladking brush, and a fine polish is the result.

BOOT-TOP LIQUID. *Prep.* I. Oxalic acid and white vitriol of each 1 oz.; water 1½ pints. *Proc.* Dissolve and apply with a sponge to the leather previously washed with water, then wash the composition off with water, and dry. This liquid is poisonous.

II. Mix in a vial, 1 drachm of oxymuriate of potass, with 2 oz. of distilled water; and when the salt is dissolved, add 2 oz. of muriatic acid. Then shake well together, mix in another vial 3 oz. of rectified spirit of wine with ½ an oz. of the essential oil of lemon, unite the contents of the two vials, and keep the liquid, thus prepared, closely corked for use. This liquid should be applied with a clean sponge, and dried in a gentle heat; after which, the boot-tops may be polished with a proper brush, so as to appear like new leather.

III. Sour milk 1 quart; gum arabic 1 oz.; juice of 2 lemons; white of 2 eggs; oil vitriol 2 oz. Mix.

IV. Sour milk 1 quart; butter of antimony, cream of tartar, tartaric acid, and burnt alum, of each 2 oz. Mix.

BORACIC ACID. *Syn.* Sedative Salt. Sed. Salt of Vitriol. Sed. Salt of Homberg. *Prep.* Dissolve borax in 4 times its weight of boiling water, then add sulphuric acid to the solution until it acquires a distinct acid reaction, (about ¼ the weight of the borax.) As the solution cools, crystals of boracic acid will be deposited. These crystals must be then placed on a filter, and washed with a little cold water. They may be still further purified by solution in boiling water and recrystallization.

Remarks. Even after this treatment, the crystals are apt to retain a little sulphuric acid or sulphate of soda, which can only be got rid of by heating them in a platinum crucible, before redissolving them and crystallizing the second time, as above described. When wanted perfectly pure for chemical analyses, this plan must be always adopted.

The boracic acid of commerce is extracted from the acid lagoons of Tuscany.

Prep. As thus obtained, this acid is soluble in 25 times its weight of cold, and 3 times its weight of boiling water. Very soluble in alcohol, which then burns with a bright green flame, offering a sure test of the presence of boracic acid. Odorless, and tastes bitter. Reddens litmus, but browns turmeric paper. It was once administered internally in large doses, (by Cullen,) but is now scarcely ever employed as a medicine.

BORATE. A compound, formed of the preceding acid and one of the bases.

Prop. The boracic acid has but a feeble affinity for the bases; most of the borates being decomposed by the stronger acids, the former being liberated in a free state. *Prep.* Many of them may be formed by digestion of the hydrate of the base in a solution of the acid, with the assistance of heat, or by double decomposition.

Tests. I. By digestion in slight excess of oil of vitriol, evaporating to dryness, powdering, and dissolving in alcohol, the latter will acquire the property of burning with a green flame. II. If to a strong and a hot solution of a borate, sulphuric acid be added in excess, crystals of boracic acid will form as the liquor cools.

BORATE OF MERCURY. *Prep.* I. Neutral borate of soda 265 grs.; calomel 222 grs.; grind together in a mortar, with a little water, then fill the mortar up with hot water; collect the red precipitate; wash and dry.

II. Add a solution of borax to a solution of quicksilver in nitric acid. Collect the precipitate as before. (White.)

BORATE OF SODA. I. (*Neutral borate.*) *Prep.* Saturate boracic acid in solution with carbonate of soda, at a boiling heat. (Berzelius.)

II. (*Biborate.*) This salt, often erroneously called borate and subborate, is the borax of commerce, and is a natural production. (See Borax.)

BORAX. *Syn.* Biborate of Soda. Borate of Soda. Subborate of Soda. Refined Borax. Crude borax is a natural production, and after being refined, forms a large portion of the borax of commerce. In its rough state it is called *crude borax, tincal, tincar,* &c. It is found crystallized on the edges and shallows of a brackish lake in Thibet, during the winter. It is also prepared by saturating the native boracic acid of Tuscany with soda. The market being literally overloaded with the former article, its price has fallen so low as to allow of its employment for this purpose with great advantage. A valuable paper on this subject, by M. Payen, appeared in the "Ann. de Chimie et de Phys." for July, 1841; and a translation of the same in "The Chemist," vol. ii. 368, to which the reader is referred for a complete account of this process.

The best Tuscany boracic acid contains only 50 per cent. of real boracic acid, and yields no more than 140 to 150 per cent. of good borax.

Prop., Use, &c. It is extensively employed as a flux for metals, for soldering, and in medicine. Internally it is diuretic, sedative, emmenagogue, and cooling, in doses of 15 to 40 grains; externally as a gargle for sore throat, and in powder as a detergent in aphthæ, and ulcerations of the mouth. Dissolved in rose-water, it is used as a cosmetic, and mixed with 8 times its weight of lard, forms a useful piles ointment.

Tests. These are the same as for the borates, which see. It reddens turmeric paper, and, before the blowpipe, fuses into glass, which may be tinged red by terchloride of gold, and blue by cobalt.

Pur. The purity and strength of borax are best ascertained by determining the quantity of sulphuric acid required to neutralize a given weight, as indicated by litmus paper. Common salt and alum are frequently mixed with borax to lower the value. The former may be detected by dissolving the borax in hot water, when a solution of lunar caustic will give a curdy white precipitate, soluble in ammonia; and the latter by water of ammonia, which will give a bulky white precipitate. The

former must be distinguished from the white pulverulent precipitate of borate of silver, which will be thrown down from pure borax.

BORAX, GLASS OF. *Prep.* Dry borax with a gentle heat, breaking down the froth as it rises, then melt it by increasing the heat until it runs into a glass. *Use.* In soldering, and as a blowpipe flux.

BORO-FLUORIDE OF HYDROGEN.—*Prep.* Pass fluoboric acid gas through water, and afterwards carefully concentrate the solution; cool and separate the crystalline powder from the solution, which is the boro-fluoride of hydrogen. *Prop., &c.* With most of the protoxides it interchanges bases, and metallic boro-fluorides result.

BORO-FLUORIDE OF BARIUM. *Prep.* Add carbonate of baryta to boro-fluoride of hydrogen, until it ceases to be dissolved; evaporate to the consistence of a sirup, when crystals will form. *Remarks.* The boro-fluoride of calcium, magnesium, and lead, may be formed in a similar way.

BORO-FLUORIDE OF POTASSIUM.—*Prep.* Drop boro-fluoride of hydrogen into a solution of carbonate of potassa, collect the white powder that falls, and wash it with cold water.

BORO-FLUORIDE OF SODIUM. *Prep.* Dissolve fluoride of sodium in boro-fluoride of hydrogen, and crystallize. *Remarks.* Boro-fluoride of lithium may also be formed in a similar way.

BORON. The base of boracic acid, discovered by Sir H. Davy, in 1807, by means of the galvanic battery of the Royal Institute.

Prep. Potassium, and perfectly dry boracic acid, or still better, boro-fluate of potassa, intimately mixed together, are to be placed in an adopter, or glass tube, and submitted to a low red heat. When cool, remove the loose cork that fastened its mouth, and pour in successive portions of hot water, until the whole matter is detached and dissolved. Collect the liquid and allow it to settle, then wash the precipitate, first with a solution of sal ammoniac, and finally, with alcohol; next dry the boron in a capsule, and put it into a well-stopped vial.

Prop., &c. A solid, tasteless, and inodorous powder, of grayish-brown color. With sulphur it unites at high temperatures, forming sulphurets; and when placed in chlorine gas it spontaneously inflames, and a gaseous chloride is produced. This gas may also be made by exposing calcined borax and charcoal at a red heat to the action of dry chlorine.

BOTTLE, RED. *Syn.* TAYLOR'S RED BOTTLE. WHITWORTH DOCTOR'S RED BOTTLE. *Prep.* British brandy 1 quart; powdered cochineal ½ oz.; oil of origanum 10 drops. Digest for 24 hours and filter.

BOUGIE. *Syn.* CANDELA. CANDELA CEREA. CANDELULA. VIRGA CEREA. CEREA. CEREOLA. CEREUS. CEREOLUS. A long slender instrument, introduced into the urethra, œsophagus, or rectum, to overcome strictures of those canals. The word bougie is the French for a wax candle.

Prep. I. Add 3 parts of boiled linseed oil to 1 part of melted amber, and when mixed add 1 part of oil of turpentine; spread the mixture at 3 successive intervals upon loose spun silk cord or web, dry in a heat of 150°, and repeat the process until the instrument has acquired the proper size, then polish, first with pumice-stone, and afterwards with tripoli and oil.

Remarks. The above is the original receipt of the French professor Pickel, and is still generally used, slightly modified, on the continent.

II. Add to the oil and amber melted together, as last, caoutchouc in the proportion of $\frac{1}{16}$ of the weight of the oil employed; when dissolved, remove the vessel from the fire and proceed as before.

Remarks. This is the plan usually adopted at Paris, and for the best elastic bougies this process usually occupies from 6 to 8 weeks. When the bougie is wanted to be hollow, a piece of polished metallic wire is introduced into the axis of the silk, or tinfoil is rolled round the wire and the composition applied as before. When dry and hard the wire is withdrawn.

III. (*Caoutchouc, or elastic gum bougies.*) *a. In France* these are made by applying a solution of Indian rubber in ether, to the silk or foil prepared as above.

b. In England, where ether is expensive, naphtha is employed, or slips of Indian rubber previously boiled in water, or that have had their edges softened with ether, are wound round the wire or foil, and kept in their place by a piece of tape applied over them, as in making elastic tubes. They are afterwards carefully smoothed off.

IV. A common kind of bougie is made by dipping pieces of catgut or soft linen into lead plaster, melted, and rolling it while yet warm upon a slab. *Very inferior.*

V. (*White.*) *Prep.* Yellow wax 1 lb.; spermaceti 1 oz.; finely-powdered sugar of lead ¾ oz.; melt and spread upon slips of old linen, then roll them up while warm with the spread side outwards.

VI. (*Bell's.*) Lead plaster 1 lb.; yellow wax 8 oz.; olive oil 2 oz.; *as last. Very inferior.*

BOUILLI. (French for boiled meat.) This name has been applied by cooks to several dishes of boiled meat, as a refinement on the plain English. Thus "beef bouilli, beef in bouilli, &c.," means, stewed or boiled beef, &c. As, however, the name is à la françaís, so must be the accompaniments, which generally consist of herbs and vegetable seasoning in greater quantity and variety than is usually deemed essential to a plain-spoken piece of boiled or stewed meat!

BOULES DE NANCY. Equal parts of iron filings and red tartar, made up into balls with spirit. *Use.* As a tonic dissolved in hot water.

BOUQUET DE LA REINE. *Prep.* I. Essence of bergamotte 1 drachm; English oil of lavender 23 drops; oil of cloves and aromatic vinegar, of each 8 drops; essence of musk 10 drops; alcohol ½ oz. Mix.

II. Oils of bergamotte and lavender 30 drops each; neroli 15 drops; oils of verbena and cloves, of each 5 drops. Essences of musk, ambergris, and jasmin, of each ½ drachm; rectified spirit of wine (strongest) 1 oz. Mix.

BOX WOOD MAHOGANY. *Prep.* Warm the wood by the fire, then wash it over with aquafortis, let it stand 24 hours to dry, and polish it with linseed oil reddened with alkanet root, or give it a coat of varnish, made by dissolving aloes and annotto in spirit of wine.

BOYLE'S FUMING LIQUOR. Hydrosulphuret of ammonia is usually employed and sold for this article, but the liquor prepared by Boyle's process contains an excess of sulphur. (Gay Lussac.) The properties of both are however the same.

Prep. Mix 4 parts of fresh slaked lime; 2 of sal ammoniac, and 1 of sulphur, then submit the mixture to distillation.

BRA GRAS. Tar, black rosin, and the dregs of strained rosin, melted together.

BRAIN CAKES. *Prep.* Clean, wash, blanch, and soak the brains, then beat them up with a little white pepper and salt, a sage-leaf or two, scalded and finely chopped, and the yelk of an egg; make them into small cakes or fritters, and fry them.

BRAN. The husk of wheat which immediately covers the grain, and which is left in the bolting machine. *Use.* It is largely employed by the calico printers, when diffused through hot water, to remove the coloring matter from those parts of their goods which are not mordanted. A handful mixed with a pail of warm water, forms an excellent emollient foot-bath. Infused in water, (*bran tea,*) and sweetened, it forms a popular demulcent, much used in coughs and hoarseness, and, taken in quantity, proves gently laxative. It also forms an excellent manure, and, from containing the ammoniaco-magnesian phosphate, is especially adapted for potatoes. It is frequently mixed with flour and made into bread, by the poorer orders.

BRANDY. *Syn.* Eau de Vie. Aqua Vitæ. Spiritus Gallicus. Brandy-wine. The spirituous liquor obtained by the distillation of wine. When first distilled it is colorless, and only acquires a yellowish tint from the wood of the casks, in which state it is known and sold as pale or white brandy. The deep color that it usually possesses, is imparted to it by adding a little spirit coloring, (burnt sugar or caramel,) and occasionally a little red sanders wood as well, and is intended to imitate the appearance acquired by brandy from great age, when kept in wood. The natural color, however, which the spirit receives from the cask, no matter how long it may have been in it, never exceeds an amber tint, about the common color of pale Jamaica rum; but the public taste has been gradually vitiated in this respect, until only a spirit of a lively and full "*brandy color*" (unless for a pale brandy) will sell.

The brandies most esteemed in England are imported from France, and are those of Cognac and Armagnac, the preference being generally given to the former. The brandies of Rochelle and Bordeaux may be reckoned next in quality, while those obtained from Portugal, Spain, and Italy are very inferior.

The constituents of brandy are alcohol and water, and small quantities of volatile oil, acetic acid, acetic ether, œnanthic ether, coloring matter, and tannin. It is from the presence of the last six of these substances that the spirit derives its distinguishing smell and flavor. The quantity of alcohol present in brandy varies from 48 to 55 per cent. When first imported, it is generally 1 or 2 overproof, but by age its strength is lessened, and by the time it is usually taken from the bond store for sale, seldom exceeds 3 or 4 underproof. From considerable personal acquaintance with the cognac trade, I feel confidence in asserting, that brandies of the best quality seldom exceed proof, and are generally below it, and that it is a common practice in France to add spirit of wine and coloring to raise the strength to any given point desired by the English purchaser, and to charge the same in the invoice; or where the purchaser is not *well acquainted with the subject,* and desires a strong spirit at a low rate, to sell him brandy so mixed as genuine. The very finest brandies average from 5 to 10 u. p., and never exceed about 2 u. p.; they then contain more than $\frac{1}{2}$ their weight of water, and from their boiling point being higher, they come over more highly charged with essential oil, and other volatile and fragrant principles of the grape, and thus possess in a greater degree that peculiar aroma and flavor for which they are so much esteemed. French brandy or wine, distilled at a low temperature in a water bath, yields a very pure and scarcely flavored spirit.

The quality of the brandy imported from France varies considerably from that which is drunk on the continent, principally from its being *prepared,* or, as it is technically termed, "*made up,*" for the London market, which means lowering it by the addition of spirit, coloring, &c. above described. The common strength at which foreign brandy is sold in England is about 11 or 12 u. p., and below 17 u. p. it becomes seizable by the excise. The strength at which it is sold and permitted in trade, is generally 10 u. p., to which it is reduced by adding water, and never less than 12 u. p., unless it be specially agreed upon. In large quantities and from bond, of course the strength depends much upon the age and quality of the spirit. A fine old brandy being, perhaps, 8 or 10 *u. p.*, while one of the last year's vintage of a commoner quality may be as strong as 2 or 1 *u. p.* But these distinctions are familiar to every experienced brandy dealer.

In France there are several varieties of this spirit distilled, which are known by names descriptive both of their quality and source. The "*eau de vie supérieure,*" or *cognac brandy,* is generally obtained from pale white wines, by careful distillation, and is remarkable for its superior flavor. When kept in glass or stone bottles, it is called white cognac brandy, and the same term is also generally applied when it has been kept in casks, but has not been artificially colored; in the latter case, however, it generally acquires a pale amber tint.

The "*eau de vie ordinaire,*" or *common brandy,* is distilled from high-colored white or red wines, and has generally a sp. gr. of 0·948, and varies from 22 to 27 u. p.

The "*eau de vie de marc*" is obtained from the lees of vinegar and other wines, the marc or cake of grapes from which the juice has been pressed, and the commonest red wines, fermented and distilled together by a quick fire, to drive over as much essential oil and flavoring as possible.

The "*eau de vie seconde*" is the weak spirit that passes over after the stronger spirit has been drawn off, and the receiver changed. *It is used* for common drinking, or mixed with other brandy.

The "*eau de vie à preuve d'Hollande*" is brandy about 19° Baume, or sp. gr. ·9420, the common strength at which it is retailed in France, and will stand the "*proof*" or "*bead.*"

The "*eau de vie à preuve d'huile*" is the strongest brandy usually drunk; it is about 23° Baume, or sp. gr. ·918; pure olive oil will just sink in it; hence the above term.

The "*eau de vie fort*" is usually prepared by the redistillation of common brandy, keeping the first portion separate. It answers to our spirit of wine. It is made of 12 different strengths, distinguished by names, exhibiting the quantity of water required to reduce the sample to the "*preuve d'Hollande.*" The weakest is called cinq-six, or $\frac{5}{6}$, and the strongest trois-neuf, or $\frac{3}{9}$, the difference between the numerator and the denominator being the quantity of water the 3 parts of the former will take to reduce it to the "*preuve,*" when it would make 9 parts. Its sp. gr. is about ·839.

The *esprit de vin* is brandy or spirit rectified to 0·890 and upwards.

The general method of distilling brandy in France differs in no important particular from that practised in England, for grain or molasses spirit. Neither are the French workmen more skilful nor more cleanly in their operations than the English. It is the materials alone that, in this case, conduce to the superiority of the product. The quality of the brandy varies with that of the wine from which it has been distilled. Every soil, every climate, every kind of grape, produces a wine possessing some peculiarity confined to itself, and this wine on distillation produces a spirit possessing like distinctions. A large quantity of brandy is prepared in France soon after the vintage, as the juice of the poorer grapes that is unfit for wine is fermented and at once distilled. It is a general rule, in France, to distil only such wines as are unsaleable, as the profits on the wine, sold as such, are much greater than when it is converted into brandy.

The Strength of Brandy may be ascertained in the same way as alcohol, for which purpose Sike's hydrometer is used in England. In France, from the value of spirit being less, it is frequently tested by simpler methods, though great accuracy obtains, in this particular, where necessary.

Pur. Very little perfectly pure French brandy is obtained by the small consumer in England, as it is not only generally lowered a little by the wholesale dealer, but undergoes a like process at the hands of the retailer. The safest method is either to procure it direct from the bond store, without its even entering a private cellar, or to buy of some known respectable party, and to pay a price that will offer no inducement to dishonesty. If this be not done, by all means buy British brandy, which is now made of excellent quality by many of the leading houses, as *Betts*, *Bretts*, *Booth*, and *Grimble*. From the two former a single sealed bottle may be procured at the same price as by the gallon.

The importation of foreign brandy for home consumption amounts to about 1,400,000 gallons a year.

BRANDY, (REDUCED.) I. To 20 gallons of Cognac brandy add 5 gallons of the best British brandy.

II. To 72 gallons of full-flavored French brandy, add 10 gallons of spirit of wine, (58 *o. p.*,) 8 gallons of water, and 1 pint of good coloring. Rummage well up and let it stand until the next day. *Remarks.* The above reduction is generally adopted in trade, and is known by the name of "*improving.*" But such is the poverty of the palate of the English brandy drinker, that the adulteration is often not suspected, even when it is carried to double the extent of the above, which is generally exceeded in the hands of the retailer. So long, however, as the foreign spirit constitutes about half of the mixture, and was at first of decent quality and age, the infatuated Englishman smacks his lips, and cunningly holding up his glass between the light and his eye, exclaims, "*Ah! this is a drop of the real.*"

BRANDY, (BRITISH.) *Syn.* British Cognac. Imitation Cognac, &c. From the heavy duty levied on French brandy imported into England for home consumption, it has become a desideratum with the distiller (rectifier) to produce an English spirit of a similar description. For some time the attempt proved quite unsuccessful, but of late years much capital and talent have been embarked in the pursuit, and the result has proved very satisfactory. An article of British manufacture may now be purchased, at a very reasonable rate, of really respectable quality, and possessing much of the flavor and aroma of foreign brandy, while, as a beverage, it is equally wholesome. Much of the British brandy, however, that is commonly met with, is of such a wretched quality as to be quite undeserving of the name, which is evidence of the fact, that much skill and experience is required to ensure success in its manufacture. For a long time this liquor was distilled from spoilt wine and dregs of wine, both British and foreign, mixed with beer bottoms and similar articles; and when, instead of these, corn, malt, and molasses spirit were employed, it was considered as an unpardonable and wicked misuse of those articles. Modern experience has proved, however, that perfectly pure and tasteless malt spirit is the best article to form into an imitation brandy.

The following formulæ, by skilful management, will produce very good brandy, but it must be recollected that much depends on the quality of the materials employed, as well as on the operator. As the strength and quality of the ingredients, and the methods of manipulation vary, so will the result; much must therefore be left to the judgment and discretion of the artist. It offers a profitable pursuit to the ingenious and industrious chemist and rectifier.

Prep. I. Take 12 gallons of the finest flavorless malt spirit at proof, (or if of a different strength a proportionate quantity;) add thereto 5 gallons of water, $\frac{3}{4}$ lb. of the best crude red tartar or winestone, previously dissolved in 1 gallon of boiling water; $\frac{1}{4}$ pint of acetic ether; 2 quarts of good French wine vinegar; 7 lbs. of bruised French plums, and 1 or 2 gallons of wine bottoms or flavor stuff from Cognac, mix them in a fresh-emptied sherry cask, and let them stand together for 14 days, frequently rummaging up the liquor with a stick; next draw over 15 gallons of the mixture from a still furnished with an agitator. Put the rectified spirit into a clean, fresh-emptied Cognac brandy cask, and add thereto $\frac{3}{4}$ pint of tincture of catechu, 1 lb. of fresh and clean oak shavings, and about a pint of good spirit coloring. Bung close, and agitate occasionally for a few days. *Remarks.* Age improves the above article, and renders it

(provided the process be well managed) of a very superior quality. The above receipt yields 15 gallons of brandy 17 *u. p.* The following forms may also be recommended:—

II. Perfectly pure spirit, pf. 99 gallons; red tartar, dissolved, 7 lbs.; acetic ether 3 lbs.; wine vinegar 3 gallons; bruised raisins, or French plums, 7 lbs.; bitter almonds, bruised, 1 oz.; water sufficient. Dissolve the tartar in the water, then add the other ingredients, macerate as before, and draw over 120 gallons; lastly, add a few lbs. of oak shavings, 1 lb. of powdered catechu made into a paste with water and burnt-sugar coloring as before. *Remarks.* This yields 120 gallons of spirit fully 17 *u. p.*

III. Clean spirit 17 *u. p.*, 100 gallons; nitric ether 2 quarts; cassia buds, ground, 4 oz.; bitter almond meal 2 oz.; orris root, sliced, 6 oz.; powdered cloves 1 oz.; capsicum 1½ oz.; good vinegar 2 gallons; brandy coloring 1 quart; powdered catechu 1 lb.; full-flavored Jamaica rum 2 gallons. Mix well in an empty Cognac cask, and let them macerate for a fortnight, occasionally stirring. *Remarks.* The proportion of the ingredients may be varied by the skilful brewer, as much depends on their respective strengths.

IV. Good plain malt spirit, 17 *u.p.*, 100 gallons; finely-powdered catechu 12 oz.; tincture of vanilla 4 oz.; burnt-sugar coloring 1 quart; good rum 3 gallons, or more; acetic or nitric ether 2 quarts. Mix well.

V. Clean spirit, 17 *u.p.*, 89 gallons; high-flavored cognac 10 gallons; oil of cassia 1½ drachms; oil of bitter almonds, essential, ½ a drachm; powdered catechu 10 oz.; cream of tartar, dissolved, 16 oz.; Beaufoy's concentrated acetic acid 3 lbs.; sugar coloring 1 quart, or more; good rum 1 gallon. Put the whole into a fresh emptied brandy piece, and let them remain a week together, with occasional agitation, then let them stand to settle. If this mixture be distilled, the French brandy, rum, coloring, and catechu, should not be added till afterwards.

VI. To colored plain spirit at 17 *u.p.*, add a little tincture of catechu, and a sufficient quantity of essential oil, distilled from wine lees, to give it a proper flavor. This oil is obtained by distillation from the wine lees, either dried and made up into cakes, or in their wet state mixed with about 7 times their weight of water. It should be dissolved in alcohol, and kept in this state, as it is apt to lose its flavor. *Remarks.* When this process is well managed a very capital article results, but it requires considerable address to conduct it well. The spirit produced by this plan is better for distillation. The brandy from any part of the world may thus be imitated, by distilling the oil from the lees of the wines produced in the particular district. This is the only method of producing an exact imitation. A pound each of finely-powdered charcoal and ground rice has been recommended to be digested in a gallon of spirit for a fortnight. Where black tea is cheap, as in America, it is very commonly employed to impart the roughness and flavor of brandy to colored spirits.

BRANDY, CHERRY. *Prep.* I. To every gallon of brandy put an equal measure of cherries, bruised between the fingers; steep for 3 days, then express the liquor; add 2 lbs. of lump sugar, and strain for use.

II. To the above add 1 quart of raspberries, and ½ a pint of orange-flower water. *** Quality very fine.

III. Treacle 1 cwt.; spirit (45 u.p.) 41 gallons; bruised bitter almonds (more or less, to taste) 5 oz.; cloves 1 oz.; cassia 2 oz. Put the ingredients into a large cask, well mix and let them lie a month, occasionally stirring.

Remarks. Equal parts of fully ripe Morello and black cherries produce the richest cordial.

BRANDY, CARAWAY. *Prep.* I. Steep 4 oz. of bruised caraway seeds and 2 lbs. of sugar in 1 gallon of British brandy, for a fortnight.

II. Sugar 1 lb.; caraways 1 oz.; 3 bitter almonds; spirits of wine and water, of each 1 quart; (or spirit 22 u.p. ½ a gallon.) Macerate as above.

BRANDY, DANTZIC. This is distilled from rye, ground with the root of calamus aromaticus. It has a mixed flavor of orrice and cinnamon.

BRANDY, LEMON. *Prep.* I. Steep ½ lb. of fresh lemon peel and ½ a dozen lemons, cut in slices, in 1 gallon of brandy, for a week, then add 1 lb. of lump sugar.

II. Proof spirit 7 gallons; essence of lemon 3 drachms; sugar 5 lbs.; tartaric acid 1 oz., dissolved in water 2 gallons; coloring q. s. Mix, and rummage repeatedly for 14 days. *Remarks.* Sometimes milk is added to the above, in the proportion of 1 quart (boiling hot) to every gallon.

BRANDY, MALT. Malt spirit, flavored with sweet spirits of nitre and terra Japonica, and colored with treacle, or spirit coloring. (See Brit Brandy.)

BRANDY, ORANGE. This may be made in a similar way to lemon brandy.

BRANDY, PEACH. *Prep.* I. From peaches, by fermentation and distillation. Much used in the United States, where peaches are very cheap.

II. Bruise the peaches, then steep them in twice their weight of British brandy, or malt spirit; lastly, express the liquor.

III. Bitter almonds (bruised) 2 oz.; proof spirit (light) 10 gallons; water 3 gallons; sugar 5 or 6 lbs.; orange-flower water ½ a pint. Mix, and macerate for 14 days.

*** Color with brandy coloring, if *required* darker.

BRANDY, RASPBERRY. *Prep.* I. Pour as much brandy over raspberries as will just cover them; let it stand for 24 hours, then drain it off, and replace it with a like quantity of fresh spirit; after 24 hours more, drain this off and replace it with water; lastly, drain well, and press the raspberries quite dry. Next add sugar to the mixed liquors, in the proportion of 2 lbs. to every gallon, along with a ¼ of a pint of orange-flower water.

II. Mix equal parts of mashed raspberries and brandy together, let them stand for 24 hours, then press out the liquor. Sweeten as above, and add a little cinnamon and cloves, if agreeable; lastly, strain.

BRASS. An alloy of copper and zinc.

Hist. and Prep. Brass was formerly manufactured by cementing granulated copper, or copper clippings, with calcined calamine and charcoal, in crucibles, exposed to a bright heat. The alloy

was found in lumps at the bottom of the crucible on cooling. These were remelted and cast into ingots. At the present day, brass is generally made by direct union of the metals. This process requires much care, owing to the different degrees of fusibility of copper and zinc. The proper quantity of zinc is first melted, and slips of copper plunged into it, which are rapidly dissolved, as it were, and the addition is continued until an alloy is formed, somewhat difficult of fusion, when the remainder of the copper is added. The brass thus formed is broken into pieces, and remelted under charcoal, and a proper addition of either zinc or copper made, to bring it up to the color and quality desired. It is next cast into plates, or other forms, in moulds of granite. When submitted to the rolling-press for reduction to *thin* plates, it requires to undergo the operation of annealing several times.

Prep. I. (*Fine Brass.*) 2 parts of copper to 1 part of zinc. *Remarks.* This is nearly 1 equivalent each of copper and zinc, if the equivalent of the former metal be taken at 63·2; or 2 equivalents of copper to 1 equivalent of zinc, if it be taken, with Liebig and Berzelius, at 31·6.

II. Copper 4 parts, zinc 1 part. An excellent and very useful brass.

III. (*Gold-colored Brass.*) *Syn.* Red Brass. Dutch Gold. Tombac. Similor. Prince's Metal. Pinchbeck, &c.

a. Copper and zinc, equal parts.

b. Copper 2 parts; zinc 1 or 1½ parts. This is Manheim gold.

c. Copper 3 to 5½ parts; zinc 1 part. Deep colored.

Remarks. The proportion of zinc in this alloy is altered to suit the color and other properties to the purposes for which it is intended, and often varies from ⅛ to ⅕, or ¼ of the weight of the alloy. At the celebrated works of Hegermühl, near Potsdam, the proportions are 11 parts of copper to *two* of zinc, which produces a metal which is afterwards rolled into sheets for the purpose of making Dutch leaf-gold.

BRASS, BUTTON. (*Best.*) I. Copper 8 parts; zinc 5 parts, as above.

II. (*Common.*) Copper 50 parts; zinc 40 parts; tin 4 parts; lead 6 parts.

BRASS, FOR SOLDER. *Syn.* Hard Solder. I. 12 parts of brass; 6 parts of zinc, and 1 of tin, melted together.

II. 2 parts of brass, and 1 of zinc.

III. (*Very strong.*) 3 parts of brass, and 1 of zinc.

BRASS, TURNER'S. 98 parts of brass, and 2 of lead. *Remarks.* The addition of lead improves the brass for the uses of the turner, but lessens its malleability.

BRASS, CLEANING OF. Brass and copper are best cleaned with sweet oil and tripoli, powdered bath-brick, rotten-stone, or red brick-dust, rubbed on with flannel and polished with leather. A strong solution of oxalic acid in water gives brass a fine color. Vitriol and spirits of salts make brass and copper very bright, but they very soon tarnish, and consequently require more frequent cleaning. A strong lye of roche-alum and water will also improve brass.

Brass inlaid work may be cleaned as follows:—Mix tripoli and linseed oil, and dip into it a rubber of hat, with which polish the work. If the wood be ebony or rosewood, polish it with a little finely-powdered elder-ashes; or make a paste of rotten-stone, a little starch, sweet-oil, and oxalic acid, mixed with water. The ornaments of a French clock are, however, best cleaned with bread-crumb, carefully rubbed, so as not to spoil the woodwork. Ormolu candlesticks, lamps, and branches, may be cleaned with soap and water. They will bear more cleaning than lacquered articles, which are spoiled by frequent rubbing, or by acids, or strong alkalis.

BRASS COATING. I. Brass plates and rods may be covered with a superficial coating of brass, by exposing them in a heated state to the fumes of melted zinc, at a high temperature. *Use.* For rolling into thin plates, or drawing into wire. The celebrated spurious gold wire of Lyons is thus made.

II. Vessels of copper may be coated with brass, internally, by filling them with water strongly acidulated with muriatic acid, adding some amalgam of zinc and cream of tartar, and then boiling for a short time.

BRASS-COLORED PIGMENT. *Syn.* Brass Bronze. *Prep.* I. (*Red.*) Grind copper filings, or precipitated powder of copper, with a little red ochre.

II. (*Yellow or gold-colored.*) Gold-colored brass, or Dutch leaf reduced to a very fine powder.

Remarks. Both these powders are mixed up with varnish, and used as a paint. No more should be mixed at a time than wanted for immediate use. They are also used by dusting them over any surface, previously covered with varnish to make them adhere. (See Oxide of Copper.)

BRASS-COLORED VARNISH. *Prep.* Dissolve 1 oz. each of pale shell lac and gum sandarach, in ¼ a pint of rectified spirit of wine.

Use. To mix up the preceding powders.

BRASS, PASTE FOR CLEANING. *Prep.* I. Soft soap 2 oz., rotten-stone 4 oz.; beat them to a paste.

II. Rotten-stone made into a paste with sweet oil.

III. Rotten-stone 4 oz.; oxalic acid 1 oz.; sweet oil 1½ oz.; turpentine enough to make a paste.

Use. To clean brass. The first and last are best applied with a little water. The second, with a little spirits of turpentine, or sweet oil. Both require friction with soft leather.

BRASS ORNAMENTS, PRESERVATION OF. Brass ornaments, when not gilt or lacquered, may be cleansed, and a fine color given to them by two simple processes. The first is to beat sal ammoniac into a fine powder, then to moisten it with soft water, rubbing it on the ornaments, which must be afterwards rubbed dry with bran and whiting. The second is to wash the brass-work with roche alum boiled to a strong lye, in the proportion of an ounce to a pint; when dry, it must be rubbed with fine tripoli. Either of these processes will give to brass the brilliancy of gold.

BRASS STAIN. I. Cut sheet-brass into small pieces, and expose it to a strong heat for 2 or 3 days, then powder it, and again expose it for several days to a like heat; again powder and sift,

and expose it a third time to heat, testing it occasionally, to see if it be properly burnt. When this is the case, a little of it fused with glass will make the latter swell and froth up.

Uses, &c It imparts to glass a green tint, passing into torquoise.

II. Calcine equal parts of plate-brass and sulphur, stratified together in a crucible, until they become friable; then powder and expose them again, as last.

Use. Imparts a calcedony red or yellow tinge to glass by fusion, according to the mode of using it.

BRAWN, CHOICE. When young, the horny parts feel moderately tender; if the rind be hard, it is old.

BRAWN, MOCK. *Prep.* Take the head and belly piece of a young porker, well saltpetred; split the head and boil it; take out the bones and cut it to pieces; then take four ox-feet boiled tender, and cut them in thin pieces; lay them in the belly piece, with the head cut small; roll it up tight with sheet tin, and boil it four or five hours. When it comes out, set it up on one end, put a trencher on it within the tin, press it down with a large weight, and let it stand all night. The next morning take it out of the tin, and bind it with a fillet, put it into cold salt and water, and it will be fit for use; it will keep a long time, if fresh salt and water are put into it every four days.

BRAZIL WOOD. *Syn.* Sapan Wood. Saint Martha Wood. Fernambuca. This wood is much used in dyeing. A decoction is made by boiling for some hours in hard spring water, and this is generally kept for some time, or until it undergoes a species of fermentation, as it is thus found to yield more permanent and beautiful colors than when employed quite new. *Use.* To dye *red.*

BRAZIL WOOD DYE. I. (*For cotton and linen.*) *a.* First boil the goods in a bath of sumach, next work them through a weak mordant of solution of tin, and then run them through the Brazil bath, lukewarm. This gives a bright red.

b. First alum the goods and rinse them, then give them a mordant of solution of tin, rinse again, and turn them through the dye-bath. This gives a rose color.

Remarks. The shades of this dye may be varied by the strength of the bath, mordant, &c. A little alum added to the Brazil-bath, gives a purple tint. 1 lb. of Brazil wood, ½ oz. of alum, and 2 oz. of tartar will dye 20 to 25 lbs. of cotton.

II. (*For silk.*) The silk, after being well alumed in the same way as wool, but at a lower temperature, is rinsed, and passed through the decoction of Brazil, just lukewarm.

Remarks. By adding a little alkali to the bath, or by passing the silk through a water holding a little alkali in solution, after it is dyed, will produce what is called the false crimson. When wanted of a very deep crimson, a little logwood is added to the Brazil-bath. In this way any shade of color may be produced.

III. (*For wool.*) Boil the wool in water holding in solution 5 parts of alum and 1 of tartar, for 1 hour; then let it lie in the cold liquor for several days, frequently moving it about; lastly, boil it in a decoction of Brazil for ½ an hour.

BRAZILINE. *Syn.* Brezilike. The coloring principle of Brazil wood, obtained by Chevreul in small orange-colored needles. It is soluble in both water and alcohol; alkalis turn it violet, acids yellow. With alum it dyes red.

BRAZING. The operation of uniting the edges of pieces of copper, brass, iron, &c., by means of hard solder.

Proc. The edges, after being filed quite clean, are covered with a mixture of hard solder and powdered borax, made into a paste with water. The whole is then allowed to dry, and afterwards exposed in a clear fire to a heat sufficient to melt the solder.

Remarks. In some cases a little silver is added to the solder, when it receives the name of "*silver solder.*"

BREAD. *Principles of bread-making, &c.* This most important article of food is made of the flour of different grains, but only those that contain gluten admit of conversion into light spongy bread. Hence it is that wheat flour is best calculated for this purpose. When flour is made into a stiff paste or dough with water, and rolled into cakes and baked, it forms biscuits, or unleavened bread, which was once the only description known. When the dough, previously to baking, is left for some time in a moderately warm place, varying from 80° to 120°, a state of fermentation comes on, formerly called the panary fermentation, but which is, in reality, the sugar of the flour gradually undergoing the process of conversion into alcohol, and resembles in every respect the same change which takes place in the manufacture of wine, beer, &c. During this process, a large quantity of carbonic acid gas is liberated, and the toughness of the dough preventing its escape, the whole mass becomes puffed up and spongy, and a light porous paste is formed, ready for baking into bread. The natural process of fermenting the dough just described, is, however, subject to much uncertainty, and is inconvenient from the time it occupies to complete it, and the tendency the dough has to run into the acetous fermentation, when it acquires a sour and disagreeable taste, and is rendered less nutritious and easy of digestion. This has led to the use of a *ferment,* which at once excites a proper state of fermentation throughout the mass, and speedily renders it light and spongy. *Leaven* or *dough,* already in a state of fermentation, was originally employed for this purpose, and the bread so made was hence called *leavened bread.* But this has been wholly superseded by barm or yeast. Thus it will be seen that all that is essential to make a loaf of bread, is to add a proper quantity of yeast to the dough, and to allow it to remain for a short time in a warm place, until it rises or becomes spongy, when it must be subjected to the operation of baking. If the process be well managed, and the flour be good, bread of superior quality will be produced.

Process of making bread. In preparing his dough, the modern baker takes a part of the water needed for the batch, and having warmed it to a temperature of about 80° or 90°, dissolves his salt therein, and then adds the yeast and a portion of the flour. These he works up into a dough, which he sets aside in a warm place usually provided for

the purpose, and called the "*kneading trough*," where it soon begins to ferment and swell up. This process is called "*setting the sponge*," and according to the proportion the water in it bears to the whole quantity that is to be used, it receives the name of "*whole*," "*half*," or "*quarter sponge*." The evolution of carbonic acid in the process of fermentation, causes the sponge to heave and swell, and when the surface bursts, it subsides, and then swells again and again in a similar manner. This action would go on for some time, if not interfered with; but the baker is careful to stop it before it has communicated a sourness to the mass. After the *first*, or at the *furthest*, after the second or *third* "*dropping of the sponge*," he adds the remaining quantity of flour, water, and salt, necessary to form the batch. These he incorporates by long and laborious kneadings, until the entire mass acquires uniformity, and is sufficiently tough and elastic to bear the pressure of the hand without adhering to it. The dough is now left to itself for a few hours, during which time fermentation goes on, after which the inflated mass is again kneaded, when it is ready to be cut into pieces and weighed. These pieces are then shaped into loaves, and set aside for an hour or two, during which time they swell up to nearly double their former size; they are then placed in the oven and baked. During this operation they continue for a time to increase in size, in consequence of the dilation of the pent-up gas by the heat of the oven, until at length the fermentation is checked, and the dough becomes too solid to admit of further alteration.

Remarks. A number of other processes are used by cooks and confectioners to make the different varieties of fancy bread, cakes, puddings, &c., most of which vary according to the peculiar characteristic it is desired to communicate to them. Thus some kinds of cakes and pastes are made to eat "*short*," as it is called, or are rendered less tenacious, and a species of brittleness imparted to them by the addition of starch and sugar. In pastry a similar effect and peculiar lightness is produced by butter or lard, while in some articles, white of egg, gum-water, isinglass, and other adhesive substances are added to produce an exceedingly light and porous mass.

The different varieties of bread made in England vary chiefly in their quality, according to the flour of which they are formed. *The best white bread* is made from the purest wheat flour; *ordinary wheaten bread*, of flour to which a little of the finest bran has been added; *seconds*, from flour containing a still larger portion of bran; and common household bread, from flour produced by grinding the whole substance of the grain without any separation of the bran. Symnel bread, manchet or roll bread, and French bread are varieties made of the purest flour, from the finest wheat, a little milk being usually added for rolls, and butter and eggs for choicer purposes. Several other minor kinds of bread are also made, varied by the addition of sundry trifles, as sugar, currants, and other palatable ingredients. The Scotch "short bread" is made from a *very thick dough*, to which butter, sugar, orange-peel, and spices, are added. (See GINGERBREAD.)

In France a number of different kinds of bread are made. The "*pain bis*" is the coarsest sort, and is made of a mixture of groats and wheat flour; the "*pain bis blanc*" is made of a mixture of oatmeal and wheat flour; the "*pain blanc*" of flour from which the finest portion has been sifted; the "*pain mollet*," or soft bread, is made of the purest wheat flour, from the finest grain; the "*pain chaland*," made from the same materials as the last, but the paste is pounded; the "*pain chapalé*" is a small variety of bread, similar to the French or roll bread of England; the "*pain cornu*" is a kind of small bread, named from being done up into four-cornered pieces; the "*pain de la reine*" is another variety of small bread, and the "*pain gruau*" is a bread which has been made of late years in Paris, prepared from the small granular particles separated from the best wheat after a slight grinding. The French have also their soup bread and their country white bread, besides several other varieties, not mentioned in the above list.

In the manufacture of white bread from damaged or inferior flour, a large quantity of alum is employed by the bakers, but with the best flour no alum is required. The utmost beauty, sponginess, and sweetness, may be given to bread without the addition of one particle of alum, provided the best materials are employed. As such is not, however, generally the case, it is a common practice with the bakers to introduce 4 or 5 oz. of alum to every sack of flour, or about 1 oz. to each bushel. The method of detecting this adulteration will be presently explained. The proper quantity of salt to be used is 6 or 7 lbs. to the sack, or 1¼ lbs. to the bushel. 1 sack of the best flour, and 6 lbs. of salt, ought to yield about 360 lbs. of *good bread*, and a sack of seconds 345 to 350 lbs. of bread.

Wheaten bread, made of pure materials, is one of the most wholesome articles of food, and has been justly termed the staff of life. When well fermented and baked, it is very easy of digestion. It should never be eaten till it has stood 24 hours after being taken out of the oven, as newer bread is apt to disagree with the stomach, frequently producing flatulence, heartburn, and indigestion.

Adult. This is often carried to a fearful extent: Mr. Accum says, "The bakers' flour is very often made of the worst kinds of damaged foreign wheat, and other cereal grains mixed with them in grinding the wheat into flour. In this capital, no fewer than six distinct kinds of wheaten flour are brought into the market. They are called fine flour, seconds, middlings, fine middlings, coarse middlings, and twenty-penny flour. Common garden beans and peas are also frequently ground up among the London bread flour.

"The smallest quantity of alum that can be employed with effect to produce a white, light, and porous bread, from an inferior kind of flour, I have my own baker's authority to state, is from 3 to 4 oz. to a sack of flour weighing 240 lbs."

"The following account of making a sack of five bushels of flour into bread, is taken from Dr. P. Markham's 'Considerations on the Ingredients used in the Adulteration of Flour and Bread,' (p. 21:) 5 bushels of flour; 8 oz. of alum; 4 lbs. of salt; ½ gallon of yeast, mixed with about 3 gallons of water.

"Another substance employed by fraudulent

bakers is subcarbonate of ammonia. With this salt they realize the important consideration of producing light and porous bread from spoiled, or, what is technically called, *sour flour*. This salt, which becomes wholly converted into a gaseous substance during the operation of baking, causes the dough to swell up into air bubbles, which carry before them the stiff dough, and thus it renders the dough porous; the salt itself is at the same time totally volatilized during the operation of baking. . . Potatoes are likewise largely, and perhaps constantly, used by fraudulent bakers, as a cheap ingredient, to enhance their profit. . . . There are instances of convictions on record, of bakers having used gypsum, chalk, and pipeclay, in the manufacture of bread."

A gentleman, lately writing from the north of England, says that he found in one sample of flour which he recently examined, upwards of 16 per cent. of gypsum, and in another 12 per cent. of the same earth.

Sometime since it was discovered that some of the bakers in France and Belgium added blue vitriol to their dough to make it take more water. It is said that they dissolved 1 oz. of this sulphate in a quart of water, and added a wine-glassful of this solution to the water necessary to make about 50 4 lb. loaves. To the credit of the English baker, no such poisonous materials have ever been found mixed with his bread. *This fraud* may be discovered by boiling a little of the bread in water, to which 5 or 6 drops of nitric acid have been added, and testing the filtered liquor with prussiate of potash, which will give a brown precipitate if copper be present.

Alum may be detected by boiling the bread in water, and adding a little chloride of barium or lime water, or a little water of ammonia, either of which will produce a white precipitate.

Chalk, whiting, burnt bones, plaster of Paris, and similar substances are easily detected by burning a little of the flour or bread in a clean open vessel, when the amount of ashes left will indicate the quantity of adulteration. The quantity of ashes left by genuine flour is very trifling indeed.

Caution. If you purchase bread from the bakers, by all means buy the *best*. When you make it yourself, however, various additions may be made of a wholesome kind, that will render it cheaper. Thus mashed potatoes, ground bran, potato farina, and several other articles may be added at pleasure. Mixing the flour up with a decoction of bran, pumpkins, Iceland moss, and some other similar substances, has been recommended, and it is said that flour so mixed will yield *one quarter* more bread than when water *alone* is used, and that it will keep good for some time.

BREAD, BEE. This is the matter collected by the bees to form the bottom of the hive; it resembles a mixture of rosin and wax; its fumes are thought to be anti-asthmatic.

BREAD, BRAN. *Prep.* I. Mix with ½ a peck of flour, containing the whole of the bran, a ¼ of a pint of small-beer yeast, and a quart of lukewarm water; stir it well with a wooden spoon until it becomes a thick batter, then put a napkin over the dough, and set it about three feet from the fire, until it rises well. Add, if requisite, a little more warm water, strew over it a tablespoonful of salt, and make the whole into a stiff paste. Put it to the fire, and when it rises, again knead it into the dough. If baked in tins, the loaves will be improved.

II. To every pound of flour add ¼ lb. of bran, and proceed as above.

BREAD, EXTEMPORANEOUS. *Prep.* I. (*Ammoniacal Bread.*) Dissolve 1 oz. of sesquicarbonate of ammonia in water, sufficient to make 7 lbs. of flour into a dough, which must be formed into loaves and baked immediately.

II. Divide the flour (8 lbs.) into two portions; mix up the first with water, holding in solution 2 oz. of bicarbonate of soda, and the second with the other portion, to which 1 oz. of muriatic acid has been added. When each mass of dough has been separately well kneaded to a proper consistence, mix them together (perfectly) as quickly as possible; form the mass into loaves, and bake immediately.

Remarks. This bread is considered very wholesome. It contains no yeast.

BREAD, FRENCH. *Prep.* I. Put 1 pint of milk into 3 quarts of water. In winter let it be scalding hot, but in summer, little more than milk-warm: put in salt sufficient. Take 1½ pints of good ale yeast, free from bitterness, and lay it in 1 gallon of water the night before. Pour off the yeast into the milk and water, and then break in rather more than ¼ lb. of butter. Work it well till it is dissolved; then beat up 2 eggs in a basin, and stir them in. Mix about 1½ pecks of flour with the liquor, and, in winter, make the dough pretty stiff, but more slack in summer; mix it well, and the less it is worked the better. Stir the liquor into flour, as for pie-crust, and after the dough is made cover it with a cloth, and let it lie to rise, while the oven is heating. When the rolls or loaves have lain in a quick oven about a quarter of an hour, turn them on the other side for about a quarter of an hour longer. Then take them out and chip them with a knife, which will make them look spongy, and of a fine yellow, whereas rasping takes off this fine color, and renders their look less inviting.

II. Proceed as for the best bread; use the finest flour, and moisten it with a little milk.

BREAD, FRENCH COUNTRY WHITE This is made without yeast.

BREAD, FRENCH SOUP. This is made by adding 1 lb. or more of salt to each sack, in the place of yeast; and it is baked in thin loaves, so as to be nearly all crust, by which means it becomes more soluble in the hot soup.

BREAD, FROM AMERICAN FLOUR. This flour requires nearly twice as much water to make it into bread, as that made from English wheat, and is therefore much more economical. 14 lbs. of American flour will make 21½ lbs. of bread, but the best sort of English flour produces but 18½ lbs. (Mrs. Rundell.)

BREAD, FROM GRAINS. "Birkenmayer, a brewer of Constance, has succeeded in manufacturing bread from the farinaceous residue of beer. 10 lbs. of this species of paste, 1 lb. of yeast, 5 lbs. of ordinary meal, and a handful of salt, produce 12 lbs. of black bread, both savory and nourishing."

BREAD, (*For one sack.*) Flour 1 sack; salt

4 lbs.; water, sufficient quantity; yeast 4 pints. Dissolve the salt in 3½ gallons of the water, (warm,) then add a little of the flour and the whole of the yeast; make a dough, and keep it in a warm place until it rises, then add more flour and warm water in the same way, and work again; after 3 or 4 hours add the remainder of the flour, and sufficient water to bring the dough to a proper consistence. When the whole mass of dough is in a proper state, it is to be cut into loaves and baked.

Remarks. The bakers employ alum in making their bread, as it not only makes the dough more retentive of moisture, but improves the color of the bread. The proportion is usually 6 or 8 oz. of alum per sack, or even more.

By this process a sack of flour will produce from 345 to 350 lbs. of *well*-baked bread, or if slack-baked, from 370 to 385 lbs. of crambling bread.

BREAD, HICK'S PATENT. This is merely bread made in the common way, but baked in an oven so arranged that the vapors arising during the process may be condensed in a suitable receiver. The condensed liquor is a crude, weak spirit, produced during the fermentation of the bread. The product will not pay the expense and trouble of the collection.

BREAD, HOUSEHOLD. (*Economical Bread.*) *Prep.* I. Remove the flake bran from the flour, and boil 5 lbs. of it in 4 gallons of water, until it is reduced to 3½ gallons; strain. With this liquor knead 56 lbs. of the flour, adding salt and yeast as for other bread. Bake the loaves for 2½ hours. (Rev. Mr. Haggett.)

II. Mix 7 lbs. of flour with 3 lbs. of mealy potatoes, previously well mashed, add 2 or 3 spoonfuls of salt, and make a dough with water; then well work it with 3 or 4 spoonfuls of yeast, and after 4 hours bake it.

BREAD, IMPROVEMENT OF. A ½ oz. of carbonate of magnesia added to the flour, for a 4 lb. loaf, materially improves the quality of the bread, even when made from the worst new seconds flour. (Professor E. Davy.) This addition is perfectly innocent.

BREAD, ICELAND MOSS. This vegetable may be made into bread, either alone, or mixed with flour. It is used, in the first case, in the state of meal, in the same way as flour; in the second case, 7 lbs. of it are directed to be boiled in 12 or 13 gallons of water, and employed to make 70 lbs. of flour into dough, which is then fermented and baked in the usual way. It is said that the above quantity of flour will produce, in this way, 160 lbs. (?) of good household bread, whereas the same flour, treated in the usual way, would not produce more than 80 lbs. A simpler mode of making this bread, is to mix 1 lb. of lichen meal with 3½ to 4 lbs. of flour. The bitterness of the lichen is extracted by soaking it in cold water.

BREAD, LEAVENED. *Prep.* Take about 2 lbs. of dough of the last making, which has been raised by barm; keep it in a wooden vessel, covered well with flour. This will become leaven when sufficiently sour. Work this quantity into a peck of flour with warm water. Cover the dough close with a cloth, or flannel, and keep it in a warm place; further, mix it next morning with 2 or 3 bushels of flour, mixed up with warm water and a little salt. When the dough is thoroughly made, cover it as before. As soon as it rises, well knead it into loaves. Observe in this process, that the more leaven is put to the flour, the lighter the bread will be, and the fresher the leaven, the less sour will it taste.

BREAD, PARIS WHITE. *Prep.* To 80 lbs. of the dough, before the yeast was added, from yesterday's baking, add as much lukewarm water as will make 320 lbs. of flour into a thin dough; as soon as this has risen, 80 lbs. are to be taken out and reserved in a warm place as leaven for the next baking, and 1 lb. of dry yeast, dissolved in warm water, is to be added to the remaining portion, which is immediately made into loaves, and shortly afterwards baked, the loaves being placed in the oven without touching each other, that they may become crusty all round.

BREAD, POTATO. *Prep.* I. To mealy potatoes, well mashed, add an equal quantity of dough, made with flour, then add a proper quantity of yeast, and mix in as much potato farina, or wheat flour, as will suffice to bring it to a proper consistence. Ferment and bake, as usual.

II. Mix equal parts of potato starch and finely-pulped potatoes, and work them into a dough over night, adding the proper quantity of yeast; the next morning work in the same quantity of potato starch, mashed potatoes, and wheat flour, adding as much hot water as may be required; let it stand to rise, then work it well, cut it into loaves, and in 2 hours put them into the oven.

BREAD, SOURNESS IN. (*To rectify.*) When the dough has become sour from the fermentation proceeding too far, or the flour being of inferior quality, the addition of about a ½ oz. of carbonate of magnesia, or a little carbonate of soda, will remove it. When it arises from the sourness of the yeast, this method is especially applicable.

BREAD, STEAM-BAKED, (*à la Vienne.*) It has been known for some time at Vienna, that if the hearth of an oven be cleaned with a moistened wisp of straw, bread baked therein immediately afterwards presents a much better appearance, the crust having a beautiful yellow tint. It was thence inferred that this peculiarity must be attributed to the vapor, which being condensed on the roof of the oven, fell back on the bread. At Paris, in order to secure with certainty so desirable an appearance, the following arrangement is practised:—The hearth of the oven is laid so as to form an inclined plane, with a rise of about 11 inches in 3 feet, and the arched roof is built lower at the end nearest the door, as compared with the farthest extremity. When the oven is charged, the entrance is closed with a wet bundle of straw. By this arrangement the steam is driven down on the bread, and a golden-yellow crust is given to the bread, as if it had been previously covered with the yelk of an egg. (Hbgen Correspondent, Sept. 27. Ann. of Chym. and Prac. Pharm.)

BREAD, TO SWEETEN, (WITHOUT SUGAR.) It is not generally known that pure starch added to flour and made into dough, will be partially converted into a species of sugar during the process of fermentation and baking, and produces sweet wholesome bread. From the experiments of Dr. Colquhoun, it appears that starch arrowroot, farina of potatoes, or similar amylaceous substances, made into a jelly with hot water, may be

employed for this purpose with advantage. It is only necessary to mix the flour up with the jelly, instead of mere water, to add yeast and salt, and to bake in the common way. Dr. Percival has recommended the addition of salep for this purpose. 1 oz. of salep dissolved in 1 quart of water; 2 lbs. of flour; 80 grains of salt, and 2 oz. of yeast, gave 3 lbs. 2 oz. of good bread; but the same weight of materials, without the salep, gave only 2½ lbs. If too much salep be added, however, it will give its flavor to the bread.

BREAD, WHITING'S, (Patent.) This is made by dividing the dough into two portions; to the one a little carbonate of soda is added, to the other, a little dilute muriatic acid; they are both well kneaded separately, then mixed together, formed into loaves, and baked immediately. No yeast is used.

BREATH, FŒTID. Scarcely any thing is more disagreeable or disgusting than a stinking breath. Various means have been proposed to remove this annoyance, depending principally on the administration of aromatics, which by their odor might smother it for a time; but these require continual repetition, and are liable to interfere with the functions of digestion. The real cause of a stinking breath is either a diseased stomach or carious teeth; when the former is the case aperients should be administered; and if these do not succeed, an emetic may be given, followed by a dose of salts, or castor oil occasionally. When rotten teeth are the cause, they should be removed; or, if this be impossible, they should be kept clean. Dirty teeth often cause the breath to smell. The use of the tooth-brush should be a daily habit. Occasionally rinsing out the mouth with a little clean water, to which a few drops of a solution of chloride of lime, or chloride of soda, has been added, is an effective method. The following lozenges have also been recommended:—

Gum catechu 2 oz.; white sugar 4 oz.; orris powder 1 oz.; make them into a paste with mucilage, and add a drop or two of neroli. One or two may be sucked at pleasure.

BREAKFAST POWDER. *Syn.* Rye Coffee. Dillenius's ditto. Hunt's Economical Breakfast Powder. Rye roasted along with a little fat. *Use.* As a substitute for foreign coffee, of which it is one of the cheapest and best.

BREE'S ANTI-ASTHMATIC PLASTER. *Prep.* Simple diachylon 1 oz.; powdered camphor and powdered opium, of each ¼ oz.; sweet oil ½ a teaspoonful. *Proc.* Melt the plaster with the oil, then remove the vessel from the fire, and stir in the powders; spread it on leather before it gets cold. *Remark.* It is better made with only half the above quantity of opium.

BREWING. The art of making beer.

General notice. Before entering on a description of the process of brewing, it will be necessary to notice the apparatus and materials required for its conduct.

The apparatus consists of,

1. *A copper or boiler* capable of holding fully two-thirds of the quantity proposed to be brewed; with a gauge-stick to determine the number of gallons of fluid at any given depth therein. A copper holding about 140 gallons is a convenient size for brewing a quarter of malt.

2. *A mash-tub*, or *tun*, capable of containing rather more than the copper.

3. *One or more tuns, or vessels*, to ferment the beer in.

4. *Three or four shallow coolers* to reduce the wort as rapidly as possible to a proper temperature for fermenting.

5. *One or two copper or wooden bowls*, for bailing, &c.

6. *A thermometer* with a scale reaching from zero to above the boiling point of water.

7. *A suitable number of casks* (clean) to contain the beer.

8. *One or more large funnels, or tunners.*

9. *Two or more clean pails.*

10. *A hand-pump* of a size proportionate to the brewing.

These articles will vary in value from £10 upwards, to many hundreds, according to the extent of the brewing; but the whole of them, necessary for a private family, may be bought for less than the former amount. By proper care they will last for 30 or 40 years, and still be in a useful state. The place where these vessels are kept, and the operations carried on, is called the "*Brewhouse.*"

The materials necessary to brew beer are, *good malt*, *hops*, and *water*, and a little *yeast*.

The *malt* is bruised or crushed in a mill before brewing, that it may be acted on the more readily by the water. It should not be ground too small, as it would then make the wort thick; the crushed malt may advantageously lie for a few days in a cool situation, by which it will attract a considerable quantity of moisture from the air, and consequently its soluble portion will be the more easily dissolved out by the water used in mashing. Pale malt may be used coarser than amber or brown malt. A bushel of malt should make a bushel and a quarter when ground, and a quarter should yield between 9½ and 10 bushels, the quantity slightly varying according to the degree of bruising it has undergone. On the large scale, malt is ground in crushing mills, furnished with iron rollers; and on a small scale, by wooden rollers or small mills worked by hand. For private brewing, the malt is generally bought ready ground, for convenience sake. (See Malt.)

The hops should be those of the previous season, and for general purposes grown in Kent; but for the finer sorts of malt liquor, East Kent hops should be used; and where it is intended to be kept for some long time, those known by the names of *Country's*, *Alton's*, or *Farnham Hops* must be employed. The quantity of hops required to a given measure of malt varies from 2 lbs. to 8 lbs. of the former, to 1 quarter of the latter, according to the nature of the brewing. For good strong beer, 4 lbs. or 4½ lbs. is usually sufficient, but when the liquor is very strong, and it is intended to be highly aromatic, and to be kept for a long period, 1 lb. of hops may be used to every bushel of malt, or 8 lbs. to the quarter. Mild porter has about 3 lbs. to the quarter, and weak common beer has frequently only about ¾ lb. of hops to the bushel of malt. A portion of hops is also frequently added to the finer sort of beer, after it is casked, as we shall presently explain.

The water should be *soft* and *clear*, the *yeast sweet* and *good*, and all the vessels and casks both

sweet and *clean*. If this be not the case, with the latter especially, the best brewing in the world will be useless.

PROCESS OF BREWING. This may be divided into

I. *The mashing*. This operation consists in placing the ground or bruised malt in a large tub or "*tun*," known by the name of the "*mash-tun*," macerating it for some time in hot water, and lastly drawing off the wort from a hole in the bottom, over which a bunch of straw, or a strainer, or false bottom, is placed, to prevent the malt passing out along with the liquor. During the process of mashing, a peculiar principle, called by chemists *diastase*, reacts upon the starch also contained in the malt, and converts it first into a species of gum, called by the French chemists "*dextrine*," and then into a species of sugar resembling that produced by the action of sulphuric acid. The greater the quantity of starch converted into sugar in this way, the stronger and finer will be the wort. It therefore becomes a desideratum with the brewer to mash at a temperature that will most fully promote this object. It has been found that the best temperature for this purpose varies from 157° to 160°, but when more than one liquor is used, the first should be something lower than the former, the next may be between the two, and the third may slightly exceed the latter, or be about 165° or 170°. The action of the first mash is merely to extract the sugar contained in the malt already formed; that of the second to convert the starch into sugar by the action of the diastase; the third to fully complete this object, as well as to carry away the remaining portions of extract.

The mashing is usually performed by filling the copper with water, and as soon as it acquires the temperature of 145° in summer, or 167° in winter, 45 gallons are run off into the mash-tun, and 1 quarter of crushed malt gradually thrown in and well mixed by laborious working, until it becomes thoroughly incorporated and no lumps remain; the agitation is then continued for 30 or 40 minutes, when 36 gallons of water from the boiler, at a temperature of 200°, are added, and the whole again well agitated until thoroughly mixed. The mash-tun is now closely covered up, and allowed to stand for an hour or an hour and a half. At the end of this time the tap is set, and the wort is drawn off into the "underback," and generally amounts to about 50 to 52 gallons: 60 gallons of water, at a temperature of 200°, are next added to the mash-tun, previously drained well, and after being well worked, the whole is covered up as before. This mash is allowed to remain for an hour, when it is drawn off, and the malt again drained ready for the third mash. This time only 35 gallons of water are added at 200°, and allowed to stand for ½ an hour, when it is run off in the same manner as before, and the malt allowed to drain. The worts are now ready for boiling.

In some cases only the first and second mash is used for strong beer, and the third kept for table, or as water to mash a fresh quantity of malt with. In Scotland (see SCOTCH ALE) the brewer only mashes *once*, and afterwards washes his malt by frequent showers or "sparges" of water, by which he gets a wort of greater strength in proportion to its quantity. In operating as above, the average or mean temperature of the first mash is 145°, of the second 170°, and of the third 180°. In winter the mean temperature may be reckoned as 6 or 7° lower. A quarter of malt in this way will produce a wort having a specific gravity by the saccharometer of 1·234, or equal to 84 lbs. of extract. (See SACCHAROMETER.)

It is calculated that 32 gallons of the water employed in the mashing remain in the grains after the wort is drawn off.

II. *Boiling*. The wort is next transferred to the copper, and heated to the boiling point as soon as possible. In large breweries where several coppers are employed, the first mash is no sooner run into the underback, than it is transferred to the wort copper, and immediately boiled, and the successive mashings added as soon as drawn off; but in private houses, where there is only one copper, the boiling cannot be commenced until the water for the last mashing is removed. In some cases the worts are brewed separately, thus producing 2 or 3 qualities of beer, viz. *strong ale or stout, beer, and table beer*. No sooner has the boiling commenced than the hops may be added, and the boiling continued for 2 or 3 hours or more. In some breweries the beer is boiled for several hours, and in Belgium it is said that this is even continued for 10 or 12 hours, but too much boiling drives off the flavor of the hops. In general, two hours good boiling will be found sufficient. In small brewings the first wort should be sharply boiled for 1 hour, and the second for 2 hours. But if intended for beer of long keeping, the time should be extended half an hour. The hops should be strained from each preceding wort, and returned into the copper with the succeeding one. Between the boilings the fire should be damped with wet cinders, and the copper door set open.

For small-beer only half an hour is necessary for the first wort, 1 hour for the second, and 2 hours for the third.

It is reckoned that $\frac{1}{8}$ to $\frac{1}{15}$ part of the wort is dissipated in steam during the process of boiling, but this must of course depend altogether on the evaporative power of the boiler and the length of time the boiling is continued.

III. *Cooling*. The boiling being finished, the wort is run off from the copper into the hopback, which is furnished with a strainer to keep back the hops. It is then pumped into large square shallow vessels called "*coolers*," where it is exposed to a good current of air to cool it down to a proper fermenting temperature as quickly as possible. This is of the utmost importance for the success of the brewing. The wort should be laid so shallow as to cool within 6 or 7 hours to the temperature of about 60°. In warm weather, the depth should not exceed 3 or 4 inches; but in cold weather it may be 5 or 6 inches. As soon as the heat has fallen to about 60°, it should be instantly tunned and yeasted.

It is reckoned that by the joint evaporation from the boilers and coolers, there is a loss of about 40 gallons per quarter.

In private families a good way is to bring the wort from the copper in pails, and to pour it into a basket or a hamper, set over the coolers, by which means the hops will be retained, and the beer run through clear.

IV. *Fermentation.* When the wort is sufficiently cool, it is run into the fermenting tuns or vessels, which in small brewings may be casks, with one of their heads removed. These are called "*gyle tuns,*" and should not be more than ⅔ full. The yeast, previously mixed with a little wort, and kept until this latter has begun to ferment, may now be added, and the whole agitated well; the tun should then be covered up, until the fermentation is well established. During this process the temperature rises from 9° to 15°.

The quantity of yeast employed, and the temperature of the wort when it is added, differ in different breweries and for different kinds of beer. From ½ to 1⅜ of yeast, taken from a previous brewing of the same kind of beer, is the quantity usually employed. The higher the temperature the less yeast necessary. In England, the temperature at which the yeast is usually added, varies from 55° to 65° Fahr. In cold weather, the heats in the coolers should be 5° or 6° higher than in mild and warm weather. For ale, in cold weather, it should be tunned as soon as it has fallen to 60° in the coolers. For porter, to 64°, and for table beer to 70°; and in warm weather, strong beer should be 4° or 5° less, and table beer 7° or 8°. Care should be also taken that the worts do not get cold before the yeast is mixed to produce fermentation. The common rule for mixing the yeast is 1½ lbs. to every barrel of strong beer wort, and 1 lb. to every barrel of table beer wort.

The commencement of the fermentation is indicated by a line of small bubbles round the sides of the tun, which, in a short time, extends over the surface. A crusty head follows, and then a fine rocky one, followed by a light frothy head. In the last stage, the head assumes a yeasty appearance, and the color is yellow or brown, the smell of the tun becoming strongly vinous. As soon as this head begins to fall, the tun should be skimmed, and the skimming continued every two hours till no more yeast appears; this closes the operation, and the beer should then be put into casks, or, in technical language, "*cleansed.*" A minute attention to every stage of this process is necessary to secure a fine flavor and a brilliant beverage.

In Scotland the temperature at which the yeast is added, is generally much lower than in England; for ale, it is from 51° to 52°, and the whole process is conducted in the cooler part of the year, so that the temperature seldom rises higher than 65° or 66°. The Bavarian beer, so much celebrated on the continent, as well as the finest kinds of East India ale, are fermented at very low temperatures.

It may be generally regarded as a rule, that the lower the temperature, and the slower, more regular and less interrupted the process of fermentation, the better will be the product and the less likely to change by age. More yeast is required in winter than in summer. Should the fermentation become slack in the gyle-tun, a little more yeast is frequently added, and the whole is roused up; but on the contrary, should the temperature rise considerably, or the fermentation become too active, the wort should be cooled a little and skimmed, or at once cleansed.

V. *Cleansing.* When the fermentation has proceeded to a certain extent, the liquor undergoes the operation called "cleansing." This consists in drawing it off from the gyle tun into other vessels, or casks, set sloping, so that the yeast, as it forms, may work off the one side of the top, and fall into the vessel placed below to receive it. In small brewings, the beer is often at once transferred from the gyle tun to the store casks, which are sloped a little until the fermentation is over, when they are skimmed, filled, and bunged up. When the operation of cleansing is not employed, the yeast is removed from the surface of the gyle tun with a skimmer, and the clear liquor drawn off into the store casks.

The process of cleansing should always commence as soon as the gravity of the liquor falls to 10 or 11 lbs. per barrel, which it usually does in about 48 hours, provided the fermentation has been well conducted. Some brewers add ¼ to ½ lb. of wheat or bean flour to the beer in the gyle-tun, shortly before cleansing, to quicken the discharge of yeast, but it is not clearly ascertained whether such a plan be advantageous or the contrary.

VI. *Storing.* As soon as the fermentation is concluded, which generally takes from 6 to 8 days, or more, the clear liquor is drawn off into the store casks, or vats, which are then closely bunged down, and deposited in a cool cellar.

VII. *Ripening.* After a period, varying from 1 to 12 months, or more, according to the nature of the brewing, the liquor will have become fine, and sufficiently ripe for use. All the attention required during this interval, is to look occasionally to see that there is no leakage, and to open the vent holes, should any oozings appear between the staves of the casks.

VIII. *Fining.* It frequently happens that malt liquor, especially porter, with all the care bestowed upon it in brewing, will not turn out sufficiently fine to meet the taste and eye of the consumer, in which case it is usually subjected to the operation of "*clarifying.*" For this purpose 1 oz. of isinglass is put into 1 quart of weak vinegar, or still better, hard beer, and when dissolved, a sufficient quantity of good beer may be added to make it measure 1 gallon. This mixture is called "finings;" 1 to 2 pints of which is the proper quantity for a barrel. The method of using it, is to put the finings into a bucket, and to gradually add some of the beer, until the bucket is three parts full, during which time it is violently agitated with a whisk, and this is continued until a good frothy head is raised upon it, when it is thrown into the barrel of beer, and the whole well rummaged up, by means of a large stick shoved in at the bunghole. In a few days the beer will usually become fine.

In some bad sorts of beer isinglass will have no effect. This may be ascertained beforehand, by trying some in a long glass tube, or vial, with a little of the finings. These should be well shaken together, and then set aside for a short time, when it will be found that the finings will rise to the top, leaving the central portion of the beer clear, if it be in a proper condition for clarifying; but if, on the contrary, they sink to the bottom, and the liquor still keeps foul, no quantity of finings, how-

ever great, will ever clarify it. This latter defect may be remedied by proceeding to fine it after the manner above described, and then adding, *after* the finings have been well rummaged up, either 1 spoonful of oil of vitriol, or gum catechu, dissolved in ½ a pint of warm water, again rummaging well for a quarter of an hour. Or 1 or 2 oz. of tincture of catechu may be used instead, mixed with a little water. Either of these additions acts chemically on the finings, in the same way as good beer does, precipitating them along with the foulness, and thus brightening the liquor. The addition of a handful of hops, previously boiled for 5 minutes in a little of the beer, and then added to the barrel, and the whole allowed to stand for a few days, before proceeding to clarify it, will generally have the same effect.

CONCLUDING REMARKS. *The nature and varieties of beer, &c.* The numerous varieties of beer met with in commerce, arise either from a difference in the materials, or the management of the brewing. Thus the *water*, but more generally the nature of the malt, or the temperature of the mashing or the fermentation, decides the character of the liquor. The difference between ale and porter arises from the color of the malt, and the distinctions between the same class of liquor, brewed from similar materials, may be referred to the mashing or the fermentation. Scotch ale and Bavarian beer differ in style from other ales, as before explained, from being fermented at lower temperatures; and porter differs from either of these, because it has been made with higher dried malt. This is the cause of the almost endless varieties of malt liquor met with in England. Every country—nay, every town and every brewer, is distinguished by the production of a different flavored beer. Besides the varieties arising from difference of quality or manipulation in the brewing of similar kinds of liquor, there are certain leading features which distinguish some of them, which has led them to be considered in the light of distinct members of the same family. These are *ale*, *beer*, and *porter*. *Ale* is a pale liquor, brewed from lightly-dried malt, and is usually met with, abounding in undecomposed saccharine matter and mucilage; *beer* is a fine, strong, well-fermented liquor, darker, less saccharine, and more alcoholic than ale. The finer class of Scotch, Bavarian, and East India ales, properly belong to this class; *porter* is a dark brown colored liquor, originally prepared from high-dried malt, but now generally made from pale malt, and colored and flavored by patent or burnt malt. *Small or table beer* is a weak liquor, containing 3 or 4 times the quantity of water that is used for ordinary beer. *Stout, brown stout, &c.* are varieties of porter, differing only in their strength. See ALE, BEER, and PORTER, in their alphabetical order.

Qualities. The characteristics of good beer are transparency and a fine color, to whatever variety it may belong; and if it has been properly brewed, this will usually be the case. Hence color and transparency become a proof of good beer. Good beer is pleasant, wholesome, and nutritious, at the same time that it is strengthening and exhilarating.

Season for brewing. The best times of year for brewing are the spring and autumn, as at those periods the temperature of the air is such as to permit the cooling of the worts sufficiently low, without having recourse to artificial refrigeration, or the use of machinery for that purpose.

Adulteration. Laws respecting brewing, &c. By the laws of England, which have existed, with slight modifications, ever since the days of Queen Anne, *nothing* is allowed to enter into the composition of beer but malt and hops. The cupidity of the fraudulent brewer has, however, frequently induced him to introduce other ingredients with the view of imparting a false strength to his liquor, or as a substitute for one or other of its constituents. Thus, *to impart bitterness*, and to lessen the quantity of hops required for the beer, *quassia, gentian, wormwood*, and *broom-tops* have been used; *to give pungency and flavor, capsicum, and grains of paradise*, (in concentrated tinctures,) *ginger, corianders, orange-peel, and caraways;* to give *intoxicating properties—opium, cocculus indicus, nux vomica, tobacco, extract of poppies and tincture of henbane;* as a *substitute for malt—molasses, coloring and sugar;* to impart a *false appearance of age—sulphuric acid, alum, green vitriol*, and *common salt*. The following is a list of the unlawful substances seized at different breweries, and brewers' druggists' laboratories in London, as copied from the minutes of the committee of the House of Commons. "*Cocculus indicus, multum, (an extract of the cocculus,) coloring, honey, hartshorn shavings, Spanish juice, orange powder, ginger, grains of paradise, quassia, liquorice, caraway seeds, copperas, capsicum, mixed drugs.*"

Sugar and coriander seeds may be mentioned as a very common addition to beer. It is said that 6 lbs. of the former, and 1 lb. of the latter, are equal in strength and intoxicating quality to a bushel of malt. The sugar is employed in a roasted state, for the sake of its color; even coffee has been used for this purpose. *Publicans* generally reduce their strong beer with water, or table beer, and add treacle, (which they call "*foots*,") and a mixture of copperas, salt, and alum, (which they call "*heading*,") to make it bear a frothy head, and in many cases, gentian, sugar, or other similar ingredients, are added to keep up an appearance of strength, and to impart a flavor.

The "*cheap beer*" sold by some taverns in London, is made by dividing the contents of *two* butts among *three* butts, filling them up with water, and adding a bladder of *porter extract* (technically termed P. E.) to each.

The desire of evading the duty on malt, led to the discovery of its being only necessary to malt ⅓ or less of the grain, this portion being sufficient to convert the starch of the other part into sugar, in the process of mashing. This plan answers well when the wort is merely intended for the production of "*grain spirit*," but beer so made is inferior in quality to that brewed wholly from malt. Inferior kinds of beer have also been made from other ingredients than barley malt; thus, the grain of other cereals may be used for this purpose, as wheat, oats, &c., and many other vegetable substances that contain starch and sugar. *Potatoes, turnips, beet root, carrots, parsnips*, and other similar roots and seeds, will all produce beer by peculiar management, but the liquor must be con-

fined to private consumption, as the law does not permit its sale. Some of the above articles produce very wholesome beer, if mashed with about $\frac{1}{10}$ or $\frac{1}{12}$ of their weight of good barley malt.

The densities of the worts employed for different kinds of beer vary considerably, as will be seen by the following table.

TABLE exhibiting the densities of different kinds of Beer.

Description.	Pounds per Barrel.	Specific Gravity.
Burton Ale, 1st Class	40 to 43	1·111 to 1·120
Do. 2d "	35 to 40	1·097 to 1·111
Do. 3d "	28 to 33	1·077 to 1·092
Ordinary Ale . . .	25 to 27	1·070 to 1·073
Common Ale . . .	21	1·058
Scotch Ale, 1st Class	40 to 44	1·111 to 1·122
Do. 2d "	33 to 40	1·092 to 1·111
Porter (ordinary) . .	18	1·050
Do. (good) . . .	18 to 21	1·050 to 1·058
Do. (double) . . .	20 to 23	1·055 to 1·060
Brown Stout . . .	23	1·064
Do. (best) . .	26	1·072
Table Beer	12 to 14	1·033 to 1·039
Table Beer (common)	6	1·014

BREWING UTENSILS, TO CLEAN AND PRESERVE. In cleaning them before being put away, avoid the use of soap, or any greasy material, and use only a brush and scalding water, being particularly careful not to leave any yeast or fur on the sides, then place them away in a clean, and moderately dry situation. Should they become tainted or mouldy, take a strong lye of pearlash, which spread over the bottoms of the vessels scalding hot, and then with the broom scrub the sides and other parts.

Or, take common salt and spread it over the coolers, &c., and strew some on their wet sides, turn in scalding water and scrub them with a broom.

Or, throw some quicklime into water in the vessel, and scrub over the bottom and sides with it; in each case well washing afterwards with clean water.

Or, wash well first with oil of vitriol diluted with 8 times its weight of water, and afterwards with clean water.

Remarks. Brewing utensils with care will last for many years. Mr. Cobbett says: "I am now in a farm-house, where the *same* utensils have been used for *forty years;* and the owner tells me that they may last for *forty years longer.*"

BRINE, RED CABBAGE. *Prep.* Steep red cabbage leaves in a strong solution of salt. *Use.* As a test for acids and alkalis.

BRINE, VIOLET. *Prep.* The same as the above, but made from the petals of the blue violet.

BRIOCHE PASTE, (IN COOKERY.) *Prep., &c.* A paste made of eggs and flour, fermented with a ttle yeast, to which a little salt, a large quantity of sugar, and half as much butter as the weight of the flour used, are afterwards added and well worked in. *Use.* As an addition to soup, a casing for lobsters, patties, eggs, &c.

BRITANNIA METAL. *Syn.* TUTANIA. A fine species of pewter.

Prep. Melt together equal parts of plate brass, bismuth, antimony, and tin, and add the mixture at discretion to melted tin, until it acquires the proper degree of color and hardness.

II. To the last add an equal part, or $\frac{1}{2}$ of its weight of metallic arsenic. To be used as *before.*

III. Melt together 1 part of antimony, 4 parts of brass, and 5 or more parts of tin. This may be used at once, as Britannia metal. (See PEWTER.)

BRITISH GUM. When starch is exposed to a temperature of 300°, (Ure,) 600°, (Brande,) it becomes brown, soluble in cold water, and ceases to strike a blue color with iodine. It is largely employed by the calico printers, as a substitute for gum.

BRISTLES AND HORSE HAIR, TO DYE. These readily take any of the usual dyes applied to cotton or wool.

BROMAL. A compound discovered by Löwig, produced by the action of bromine on alcohol, hence the name, from the first portion of the name of each constituent. (See CHLORAL.)

BROMATES. Compounds of the bases with bromic acid, which see. *Char., Tests, &c.* When heated they evolve oxygen, and become bromides; with nitrate of silver and the proto-salts of mercury, they give white precipitates; that with the former is insoluble in nitric acid, but very soluble in ammonia. If a few drops of muriatic acid be added to a bromate, and it be then shaken with a little ether in a glass tube, a solution of bromine is obtained.

BROMBENZOIC ACID. A new acid, discovered by Peligot, and prepared by exposing benzoate of silver to the vapors of bromine, until they cease to be absorbed, when the acid is dissolved out with ether and obtained by evaporation.

BROMIC ACID. An acid composed of oxygen and brome.

Prep. Add sulphuric acid to a solution of bromate of baryta, until all the earth be thrown down, particularly avoiding an excess of acid; then concentrate the liquor by heat, until it be of the consistence of a sirup.

Prop. If the evaporation be carried too far, the acid will be decomposed. This acid forms salts with the bases, called bromates, which are very similar to the chlorates and iodates. *Bromate of potassa* may be made by agitating bromine with a concentrated solution of caustic potassa, collecting the crystalline white powder that falls down, and purifying it by solution in boiling water, and crystallization. *Bromate of silver* is formed by adding a solution of bromate of potassa to another of nitrate of silver.

BROMIDE. A compound form of a base and bromine. (See BROMINE.)

Char. and Tests. The soluble bromides give white precipitates with nitrate of silver, acetate of lead, and protonitrate of mercury. That from the first of these is insoluble in ammonia water, unless concentrated. A few drops of liquid chlorine poured upon a bromide, and the mixture agitated with a little sulphuric ether, yields an ethereal solution of bromine.

BROMIDE OF AMMONIA, may be formed by the mixture of ammoniacal and hydrobromic acid gases, or liquid hydrobromic acid and liquor of ammonia, or by putting bromine into water of ammonia.

Prep. This salt may be obtained by evaporation

in the form of solid white prismatic crystals. It is volatile and easily decomposed.

BROMIDE OF CARBON. (Discovered by M. Serullas.) *Prep.* Brome 2 parts; periodide of carbon 1 part, mix; just enough solution of potassa is added to make the liberated iodine disappear. The liquid bromide of carbon, which collects at the bottom of the solution, is then separated from the supernatant portion, and allowed to stand until it becomes clear. A few crystals of iodide of potassium rise to the surface, and may be removed. The clear liquid is then put into a little water slightly alkalized with potassa, to remove a little remaining iodide of carbon, after which it is quite pure.

BROMIDE OF IODINE. Bromine and iodine unite rapidly by mere mixture. By careful distillation a red vapor is obtained, which, on cooling, condenses into red crystals, of a form resembling fern leaves. This is said to be the *protobromide*. By adding more bromine, these crystals are converted into a fluid, said to be the *bibromide*.

BROMIDE OF SULPHUR. This is made by dissolving sublimed sulphur in bromine; it is a reddish, oily-looking fluid, easily decomposed, especially by water.

BROMINE. *Syn.* Brome. An elementary substance, discovered by M. Balard, of Montpellier, in 1826.

Prep. A current of chlorine is passed through the uncrystallizable residuum of sea-water, called *bittern*, which then assumes an orange tint, in consequence of bromine being set free from its combinations; sulphuric ether is then agitated with it, and the mixture is allowed to stand until the ethereal portion, holding the bromine in solution, floats upon the surface. This is then carefully decanted, and agitated with a solution of potassa, by which means bromide of potassium and bromate of potash are formed.

The whole is next evaporated to dryness, and submitted to a dull red heat; the residuum is then powdered, mixed with pure peroxide of manganese, and placed in a retort; sulphuric acid, diluted with half its weight of water, is now poured in. Red vapors immediately arise, and condense into drops of bromine, and are collected by plunging the neck of the retort to the bottom of a small receiver, containing cold water. The bromine forms a stratum beneath the water, and may be collected and further purified, by distillation from dry chloride of calcium.

Prop., Use, &c. A dark, reddish-colored liquid, having an odor resembling chlorine. It freezes at —4°, boils at 116·5°, is about 3 times as heavy as water, is very soluble in ether, less so in alcohol, and only slightly so in water. With hydrogen it forms hydrobromic acid, and with the bases, compounds called bromides, or hydrobromates. It possesses similar medicinal properties to iodine, and has been administered in goitre, scrofula, &c., in the form of an aqueous solution, composed of 1 part of bromine to 4 of water; 5 or 6 drops being the dose. This solution has also been used as a lotion.

Tests and Antidotes. The solution of chloride of gold gives a red tinge with hydrobromic acid, or an electro-positive hydrobromate.

When bromine exists in an organic mixture, caustic potassa should be added to the mass, which should then be reduced to an ash, exhausted by distilled water, and chlorine passed through the solution, or the chloride of gold added to it, previously carefully neutralized by hydrochloric acid. When chlorine is used, starch may render the presence of the element more perceptible. Nitrate of silver is also a delicate test, where the bromine is not mixed with chlorine; the bromide of silver is distinguished from the chloride by heating with hydrochloric acid and chlorite of lime, when ruddy fumes are evolved, if bromine is present.

M. Barthez has proposed magnesia as an antidote for bromine. From several experiments, it appears that the bromide of magnesium is by no means an active salt; neither is it inert. From experiments performed on rabbits, I conclude starch in solution, and white of egg, to be excellent antidotes to the poison. (Dr. Glover, Med. and Sur. Jour., No. 152.)

BROMINE, CHLORIDE OF. *Prep.* Transmit a current of dry chlorine through brome, and condense the disengaged vapors in a receiver surrounded with ice. *Prop.* A volatile reddish fluid, soluble in water, without decomposition.

BRONCHITIS. An inflammation of the mucous lining of the bronchia, or smaller ramifications of the windpipe. In its milder form it is commonly called "*a cold on the chest.*"

Symp. Hoarseness, dry cough, a slight degree of fever, followed by expectoration of mucus, at first thin, and afterwards thick and copious. In the severer forms, there is more fever, cough, and oppression at the chest, &c.

Treat. The generality of cases of bronchitis yield to small and repeated doses of ipecacuanha, and antimonial diaphoretics, at the same time adopting a light diet, and keeping the bowels open with mild purgatives.

BRONZE. A metallic alloy, composed principally of tin and copper, remarkable for the exactness of the impressions which it takes by moulding, as well as its durability; and hence, extensively employed in the casting of busts, medals, and statues. Bell, cannon, and speculum metal are varieties of bronze. In ancient times, when the manufacture of steel was ill-understood, cutting instruments were frequently made of this alloy. For statuary work, the great desideratum is to obtain an alloy capable of flowing freely into the most minute outlines of the mould, hard, and yet tough, and capable of resisting the corroding action of the weather. It must also acquire that peculiar antique green appearance, that is so much admired in bronzes.

When only a small quantity of the alloy is required, it is prepared in crucibles, but for statues or larger works, on reverberatory hearths. The fusion of the mixed metals must be conducted under pounded charcoal, and as rapidly as possible. When melted, it must be frequently stirred together to produce a perfect mixture, before casting. Coal is the fuel principally employed for the furnaces.

The proportions of the materials so vary in different castings, that it is almost impossible to say precisely what quantities are the best. The following may be regarded as good specimens. (See also Cannon, Bell, and Speculum Metal.)

BRONZE, (FOR STATUARY.) I. Copper 88 parts; tin 9 parts; zinc 2 parts; lead 1 part.

II. Copper 82½ parts; tin 5 parts; zinc 10½ parts; lead 2 parts. These are very nearly the proportions in the celebrated statue of Louis XV.

III. Copper 90 parts; tin 9 parts; lead 1 part.

IV. Copper 91 parts; tin 9 parts.

BRONZE, (FOR MEDALS.) I. Copper 89 parts; tin 8 parts; zinc 3 parts. *Remarks.* This metal assumes a beautiful antique appearance by age, and takes a good impression by stamping.

II. Copper 95 parts; tin 4 or 5 parts. These are the proportions recommended by M. Chaudet, who casts it in moulds made of bone-ash, like cupels, and afterwards finishes and polishes the medals in a coining press. This is also excellent for any small castings.

BRONZE, (FOR CUTTING INSTRUMENTS.) Copper 100 parts; tin 14 parts.

Remarks. M. Dussaussy says that the above alloy, when hardened and tempered after the manner of the ancients, will yield an edge nearly equal to that of steel. Several analyses have been made of ancient cutting instruments, whence it appears that the proportion of tin varies from 4 to 15 per cent., which tends to prove that more depends on the exact mode of tempering the alloy, than on the relative quantities of the ingredients. Zinc and tin are inadmissible in bronze for this purpose. One or 2 per cent. of iron might, nevertheless, be added with advantage. The ancient bronze used for springs, contained only 3 to 4 per cent. of tin.

BRONZE, (FOR MORTARS.) Copper 93 parts; lead 5 parts; tin 2 parts.

Remarks. The edges and lips of mortars must be tempered by heating them to a cherry red, and then plunging them into cold water; as unless so treated, they are very apt to be broken.

BRONZE, (FOR ORNAMENTAL WORK, TO BE GILDED.) I. Copper 82 parts; zinc 18 parts; tin 3 parts; lead 2 parts.

II. Copper 83 parts; zinc 17 parts; tin 1 part; lead ½ part.

BRONZE POWDERS. I. (*Beautiful red.*) *Prep.* Mix together sulphate of copper 100 parts; carbonate of soda 60 parts; apply heat until they unite into a mass, then cool, powder, and add copper filings 15 parts; well mix, and keep them at a white heat for twenty minutes, then cool, powder, and wash and dry.

II. (*Gold colored.*) *Prep. a.* Verdigris 8 oz.; tutty powder 4 oz.; borax and nitre, of each 2 oz.; bichloride of mercury ¼ oz.; make them into a paste with oil, and fuse them together. *Used* in japanning as a gold color.

b. Dutch leaf reduced to an impalpable powder by grinding.

III. (*Iron colored.*) Plumbago finely powdered.

IV. (*Silver white.*) *Prep.* Melt together 1 oz. each of bismuth and tin, then add 1 oz. of running quicksilver; cool and powder.

BRONZING OF MEDALS, AND ORNAMENTS OF COPPER, ELECTROTYPES, &c. *Proc.* I. Having thoroughly cleaned and polished the surface of the specimen, with a brush apply the common crocus powder, previously made into a paste with water. When dry, place it in an iron ladle, or on a common fire-shovel, over a clear fire for about 1 minute; and when sufficiently cool, polish with a plate-brush. By this process a bronze similar to that on tea-urns is produced; the shade depending upon the duration of the exposure to the fire. (Chemist, iii. 49.)

II. By substituting finely-powdered plumbago for crocus powder in the above process, a beautiful, deep, and permanent bronze appearance is produced.

III. Rub the medal with a solution of livers of sulphur, or sulphuret of potassium, then dry. This produces the appearance of *antique* bronze very exactly.

IV. Dissolve 2 oz. of verdigris and 1 oz. of sal ammoniac in 1 pint of vinegar, and dilute the mixture with water until it tastes but slightly metallic, when it must be boiled for a few minutes, and filtered for use. Copper medals, &c., previously thoroughly cleaned from grease and dirt, are to be steeped in the liquor at the boiling point, until the desired effect is produced. Care must be taken not to keep them in the solution too long. When taken out, they should be carefully washed in hot water, and well dried. *Gives an antique appearance.*

V. (*Chinese method.*) Make a paste with 2 oz. each of verdigris and vermilion; 5 oz. each of alum and sal ammoniac, all in fine powder, and vinegar q. s.; then spread it over the surface of the copper, previously well cleaned and brightened, uniformly warm the article by the fire, and afterwards well wash and dry it, when, if the tint be not deep enough, the process may be repeated. The addition of a little blue vitriol inclines the color to a chesnut brown, and a little borax to a yellowish brown. Much employed by the Chinese for copper tea-urns.

VI. Dissolve 1 oz. of sal ammoniac, 3 oz. cream of tartar, and 6 oz. of common salt, in 1 pint of hot water; then add 2 oz. of nitrate of copper, dissolved in ½ a pint of water; mix well, and apply it repeatedly to the article, placed in a damp situation, by means of a brush moistened therewith. *Effect.* Very antique.

VII. Salt of sorrel ¼ oz.; sal ammoniac 1 oz.; distilled vinegar 2½ pints; dissolve. As last.

BRONZING, SURFACE. This term is applied to the process of imparting to the surfaces of figures of wood, plaster of Paris, &c., a metallic appearance. This is done by first giving them a coat of oil or size varnish, and when this is nearly dry, applying with a dabber of cotton or a camel-hair pencil, any of the metallic bronze powders; or the powder may be placed in a little bag of muslin, and dusted over the surface, and afterwards finished off with a wad of linen. The surface must be afterwards varnished.

Paper is bronzed by mixing the powders up with a little gum and water, and afterwards burnishing.

Iron castings may be bronzed by thorough cleaning, and subsequent immersion in a solution of sulphate of copper, when they acquire a coat of the latter metal. They must be then washed in water.

BROOM ASHES. *Prep.* Burn broom stalks and collect the ashes. Sometimes used as a diuretic in dropsy.

BROOM COFFEE. Broom seeds, roasted

with a little butter and then ground. *Use.* As a substitute for coffee.

BROOM, SALT OF. Obtained by dissolving broom ashes in water, filtering and evaporating. *Remarks.* Antacid, consists principally of carbonate of potassa. Sometimes used in dropsy.

BROTH, (IN COOKERY.) The liquor in which meat is boiled; it is distinguished from soup by its inferior strength and quantity of seasoning, &c. The general method of preparing broth is similar to that of soup, to which article the reader is referred.

BROWN DYE. The different shades of this dye vary from pale yellow and reddish brown, up to very dark brown, almost black, every shade of which, however, may be produced as the taste of the workman may dictate, by mixtures of reds and yellows with blues and blacks, or by simple dyes, which at once impart a brown,—as catechu, walnut rinds, or oxide of manganese.

I. (*For Wool.*) *α.* Boil the cloth in a mordant of alum, and common salt dissolved in water, then dye it in a bath of logwood, to which a little green copperas has been added. The proportion of alum should be 2 oz., and of salt 1 oz., to every pound of cloth.

β. Boil the goods in a mordant of alum and sulphate of iron, then wince them through a bath of madder. *Remarks.* The tint depends on the relative proportions of the alum and copperas; the more of the latter, the darker will be the dye. The joint weight of the two should not exceed ⅛ of the weight of the wool. The best proportions are 2 parts of alum and 3 of copperas.

γ. Give the wool a mordant of alum and tartar, then pass it through a madder bath, which will dye it red. It must now be run through a black bath of galls and sumach, or logwood, to which a little acetate or sulphate of iron has been added.

δ. Proceed to mordant the cloth as last, and dye in a madder bath, then remove it and add a little acetate or sulphate of iron, and again pass it through the bath, until the required tint is produced.

ε. Give the cloth a light blue ground with indigo, then give it a mordant with alum, wash in water, and run it through a bath of madder.

ζ. Give the cloth a mordant of alum and tartar, then pass it through a madder bath, and afterwards through a bath of weld or fustic, to which a little iron liquor has been previously added. In this way every shade from mordoré and cinnamon to dark chesnut may be dyed.

η. Boil 1 lb. of fustic chips for 2 hours, and pass the cloth through the bath for 1 hour, take it out and drain, then add 1¼ oz. of green copperas, and ½ lb. of good madder, and pass the cloth again through the bath, until the proper tint is produced. This makes bronze browns, but by varying the proportion of the mordant, other shades may be produced.

II. (*For Silk.*) *α.* Give the silk a mordant as before described, then dye in a bath made by mixing the equal parts of decoction of logwood, fustic, and Brazil wood. The shade may be varied by mixing the decoctions in different proportions. *Brazil wood reddening, logwood darkening,* and *fustic yellowing,* the tint.

β. Dissolve 4 oz. of annotto and 1 lb. of pearl-ash in boiling water, and pass the silk through it for 2 hours, then take it out, squeeze it well and dry; next give it a mordant of alum, and pass it *first* through a bath of Brazil wood, and afterwards through a bath of logwood, to which a little green copperas has been added; wring it out and dry; afterwards rinse well.

III. (*For Cotton and Linen.*) *α.* Give the pieces a mixed mordant of acetate of alumina and acetate of iron, and then dye them in a bath of madder, or madder and fustic. When the acetate of alumina predominates, the dye has an amaranth tint. The iron darkens it.

β. First gall the goods, then turn them for a short time through a black bath, next give them a mordant of sulphate of copper, and pass them through a decoction of fustic, afterwards through a bath of madder, and again through the solution of sulphate of copper; drain, dry, and rinse well, then finish with a boil in soap and water. This gives a chesnut brown.

γ. First give a mordant of alum, then pass the goods through a madder bath, and next through a bath of fustic, to which a little green copperas has been added. This gives a cinnamon brown.

Remarks. Browns may be also dyed at once, by what are called substantive or direct dyes; thus—

I. *Decoction of oak bark* dyes wool a fast brown of various shades, according to the quantity employed. If the cloth be first passed through a mordant of alum, the color is brightened.

II. *Infusion or decoction of walnut peels* dyes wool and silk a brown, which, like the preceding, is brightened by alum. The older the liquor the better.

III. *Horse-chesnut peels* also give a brown. A mordant of muriate of tin turns it on the bronze, and sugar of lead the reddish brown.

IV. *Catechu, or terra japonica,* gives cotton a brown dye; blue vitriol turns it on the bronze, and green copperas darkens it, when applied as a mordant, and the stuff dyed in the bath boiling hot. Acetate of alumina as a mordant brightens it. The French color, called "carmelite," is given with 1 lb. of catechu, 4 oz. of verdigris, and 5 oz. of sal ammoniac.

V. *Sulphate or muriate of manganese,* dissolved in water with a little tartaric acid, gives the bronze tint called "solitaire." The stuff, after being passed through the solution, must be turned through a weak lye of potash, and afterwards through another of chloride of lime, to brighten and fix it.

VI. *Prussiate of copper* gives a bronze or yellowish-brown to silk. The piece well mordanted with blue vitriol, may be passed through a solution of *prussiate of potash.*

BROWN PIGMENTS. The principal and most useful of these are, umber and terra di sienna, both burnt and raw. Brown may also be made of almost any shade, by the admixture of blacks with reds and yellow, or with greens, in different proportions.

BROWNING, (IN COOKERY.) A fluid preparation used to color and flavor gravies, soups, &c.

Prep. I. Melt 4 oz. of sugar in a frying-pan, or other convenient vessel, with water, add 1 oz. of butter, and continue the heat until the whole is turned quite brown; then pour in 1 pint of port

wine, stirring well all the time, and remove the pan from the fire. When the whole of the roasted sugar is dissolved, pour it into a bottle, and add ½ oz. each of bruised pimento and black pepper; 6 shalots cut small; a little mace and finely-grated lemon-peel; and a quarter of a pint of mushroom catsup. Digest for a week, occasionally shaking; then strain through a piece of muslin, and preserve for use.

II. Instead of port wine use water, and add a glass of spirits.

III. Sugar coloring 1 pint; salt ¼ lb.; mushroom catsup ½ pint; add spice.

IV. Lump sugar (powdered) 2½ lbs.; salad oil ¼ lb.; heat in an iron vessel until quite brown, then add port wine 1 quart; Cape wine 3 quarts; shalots 6 oz.; mixed spice 4 oz.; black pepper 6 oz.; mace 1 oz.; salt ¾ lbs.; lemon juice ½ pint; catsup 1 quart.

V. Good spirit, or sugar coloring, and mushroom catsup, of each 1 gal.; Jamaica pepper, black pepper, and shalots, of each 4 oz.; cloves, cassia, and mace, bruised, of each ¾ oz.; boil in a covered vessel for 5 minutes, then digest for 14 days, and strain.

BROWNING FOR GUN BARRELS. *Prep.* I. Mix 1 oz. each of aquafortis and sweet spirits of nitre; 4 oz. of powdered blue vitriol; 2 oz. of tincture of iron, and water, 1½ pint; agitate until dissolved. *Use.* Rub this on the barrel, previously well polished, and afterwards cleaned off with whiting to remove the oil. Let it remain till the next day, then rub it off with a stiff brush. The liquid may be again applied until a proper color is produced. When this is the case, wash in pearlash water, and afterwards in clean water, and then polish, either with the burnisher or with bees-wax; or apply a coat of shellac varnish. (See below.)

II. Blue vitriol and sweet spirits of nitre, of each, 1 oz.; water 1 pint; dissolve as last.

III. Mix equal parts of butter of antimony and sweet oil, and apply the mixture to the iron previously warmed.

Remarks. The varnish used for gun barrels, after they are bronzed, is made by dissolving 1 oz. of shellac and one or two drachms of dragon's blood, in a quart of alcohol; and filtering the solution through blotting paper into a bottle, which must be kept closely corked.

BRUCINE. *Syn.* Brucia. Brucina. Vomicina. A vegetable alkali, discovered by Pelletier and Caventou, in the bark of the Brucia antidysenterica, and afterwards combined with strychnia in nux vomica.

Prep. Digest ether on the powdered bark of brucia antidysenterica, to separate a fatty matter; strain, add alcohol at 36° Baume; digest, filter, evaporate to dryness; dissolve the mass in water, add liquid subacetate of lead; filter, pass sulphureted hydrogen gas through the clear liquor; filter again, and add calcined magnesia; filter again, wash the sediment very slightly with cold water, dry, digest in alcohol, filter, and distil off the spirit. To purify the brucine, add a solution of oxalic acid, crystallize, add a mixture of alcohol at 40° Baume, and ether at 60°, to extract the coloring matter, then dissolve the oxalate of brucine in water, add calcined magnesia, filter; digest the sediment in alcohol, filter, and let the spirit evaporate by exposure to the air.

Prop., Use, &c. The crystals thus obtained are soluble in 850 parts of cold and 500 parts of boiling water. When added to the dilute acids until they are neutralized, brucia forms crystallizable salts, easily obtained by evaporation. Of these, the sulphate and bisulphate, the muriate, phosphate, nitrate and binitrate, acetate, oxalate, and some others have been examined. Most of these, especially the first three or four, are very soluble in water. Its physiological effects are similar to strychnia, but it is said to possess only $\frac{1}{12}$ of the strength of that alkali. According to Dr. Fuss and Professor Erdeman, it is not a distinct alkaloid, but a compound of strychnia and resin. *Dose.* ¼ gr. to 2 or 3 grs. daily, in the form of pills or solution. It is given in similar cases to those for which strychnia is prescribed: viz. paralysis, impotence, and other affections of the nervous system. It is a violent poison. Its antidotes are the same as those for strychnia. *Tests.* Nitric acid gives it a fine red color, which is removed by sulphureted hydrogen and sulphurous acid. Iodic acid, chloric acid, and chlorine, also turn it red.

BRUCINE, PILLS OF. *Prep.* Brucia 2 grains; conserves of roses and liquorice powder, of each, 1 scruple; mix and divide into 16 pills. *Dose.* 1 to 6 daily, at first, gradually increasing the dose.

BRUISES. *Treat.* These may be rubbed with a little opodeldoc or soap liniment; or if the inflammation be considerable, they may be washed with a little weak goulard water, or leeches may be applied to the part.

BRYONIN. A peculiar bitter principle, extracted from the white bryony or mandrake root. It is obtained from the expressed juice by filtration, evaporation to dryness, and re-solution in alcohol. It is a drastic purgative and poisonous. It forms a yellowish white mass.

BUBBLE AND SQUEAK, (in Cookery.) *Prep.* Cut slices from a cold round of beef; let them be fried quickly until brown, and put them into a dish to keep hot. Clean the pan from the fat; put into it greens and carrots previously boiled and chopped small; add a little butter, pepper, and salt; make them very hot, and put them round the beef with a little gravy. Cold pork boiled is a better material for bubble and squeak than beef, which is always hard; in either case the slices should be very thin and lightly fried.

BUGS. Various means have been proposed to drive away these nocturnal marauders and enemies of "*tired nature's sweet restorer, balmy sleep.*" Among the most certain of these is cleanliness. The furniture brokers put articles infested with this insect population into a room with doors and windows fitting quite close, when they subject them to the fumes of burning sulphur or chlorine In the small way, poisonous mixtures are frequently resorted to, with which the articles are washed. The following form is that usually employed:—

Corrosive sublimate and muriatic acid, of each, 1 oz.; water 4 oz. Dissolve, then add turpentine and decoction of tobacco, of each, ½ of a pint. Mix.

*** For the decoction of tobacco, boil 2 oz. of

tobacco in a pint of water. This mixture must be applied with a paint brush. *Caution.* This wash is a "*deadly poison!*"

The following extract may be of assistance to persons interested in the matter:—"These pests exist only in dirty houses. A careful housewife or servant will soon completely destroy them. The surest method of destruction is to catch them individually when they attack the person in bed. When their bite is felt, instantly rise and light a candle and capture them. This may be troublesome, but if there be not a great number, a few nights will finish them. When there is a large number, and they have gained a lodgment in the timbers, take the bed in pieces, and fill in all the apertures and joints with a mixture of soft soap and Scotch snuff. A piece of wicker-work, called a bug-trap, placed at the head of the bed, forms a receptacle for them, and then they may be daily caught till no more are left. Fumigations are very dangerous, and rarely effectual, therefore attempt no such project. Oil-painting a wall is a sure means of excluding and destroying them." (Chamber's Information for the People, No. 91, p. 653.)

BUNION. *Cause and Treat.* The *bunion*, or swelling on the ball of the great toe, is produced by the same cause as the corn—pressure and irritation by friction. The treatment recommended for corns will succeed in cases of bunions; but in consequence of the greater extension of the disease, the cure of course is more tedious. When a bunion is commencing, it may be effectually stopped by poulticing, and then opening with a lancet; but this requires caution, and should be performed with care.

BUNS. *Prep.* I. (*Cross Buns.*) To flour 2½ lbs., add sifted sugar ½ lb., and a little coriander seed, cassia, and mace, powdered fine, then make a paste with butter ½ lb., dissolved in hot milk ½ a pint, work in 3 tablespoonfuls of yeast and a little salt; set it before the fire for an hour to rise, then make it into buns, and again set them before the fire on a tin for half an hour; lastly, brush them over with warm milk, and bake them to a nice brown in a moderate oven.

II. (*Madeira.*) Butter 8 oz.; 2 eggs; flour 1 lb.; powdered sugar 6 oz.; half a nutmeg, grated; powdered ginger and caraway seeds, each 1 teaspoonful; work well together, then add sherry wine 1 glassful, and as much milk as required. Bake in tins in a quick oven.

III. (*Plain.*) *a.* Flour 2 lbs.; butter ¼ lb.; sugar 6 oz.; a little salt, powdered caraway and ginger; make a paste with yeast, 4 spoonfuls, and warm milk a sufficient quantity, then proceed as in No. I.

b. To the last add currants, well washed, ½ lb.

IV. (*Rich.*) Dried and warm flour 3 lbs.; powdered sugar 1 lb.; butter 2½ lbs., melted and beat with rose water 4 oz.; form into a light paste, with ¾ of a pint of yeast, and place it for an hour to rise, then add a little candied lemon and orange peel, and 1 lb. of currants, and make the whole into buns; set them before the fire for 40 minutes, then wash them over with milk, and put a little grated peel and a few caraway comfits on the top of each.

BURGLARIES, TO PREVENT. "In addition to the usual precautions of locks and bolts, alarum bells and firearms, three things have been found efficacious in preserving houses from nightly depredators. 1st. A *light* in the upper part of the house. 2d. A *small dog*, in a room on the ground floor, which offers the means of its running into a place of safety from its enemies: not to be fed too high, and allowed to sleep by day. 3d. Some *ashes* fresh from the fireplace spread before the door, underneath the window or other place. Thus the thieves' shoes will creak, the dog will be roused and bark, and the fear of detection by the approach of the light, will deter rogues of common feeling. At least, should they enter, the dog cannot be readily come at to be slain; and the scuffle occasioned by effecting this necessary prelude to robbery, will, in almost all cases, promote interruption from within or without."

BURNS AND SCALDS. These are too well known to require description.

Treat. When the injury is merely superficial, a little creosote may be applied to the part, and if it be a scald, the vesicle may be first pierced with a needle, and the aqueous fluid gently squeezed out. When creosote is not to be procured, a liniment formed with equal parts of soft soap, basilicon ointment, oil of turpentine and water may be used instead. When the part is very hot and painful, a poultice may be applied, on the surface of which a few drops of creosote, or the liniment, should be spread with a knife. This treatment will generally allay the pain, after which a dressing of any simple ointment may be adopted. In many severe flesh burns which I have had the misfortune to receive, I poured creosote *plentifully* over the part, which produced scarcely any smarting or pain, as is frequently asserted, whilst it removed the burning sensation that previously existed, and the charred surface assumed a dry scabby appearance, which, by dressing with simple ointment, soon came off and left the part beneath both sound and healthy. If a poultice be applied, it is best to keep it on until the next day, when in general a little spermaceti ointment spread on a bit of soft linen may be used instead. Plunging the part into cold water *immediately* on the receipt of an injury of this kind will frequently prevent any further remedy being necessary. In all cases of burns and scalds, it is necessary to observe that if fever should ensue, laxative medicines, as castor oil and epsom salts, should be administered.

BURNING LENS, CHEAP AND SIMPLE. Take two circular discs of plate glass, of the requisite dimensions, and place one at each end of a shallow tube; an inch long will be quite sufficient for any size; they are kept in their position very firmly by means of screw clamps, in an analogous manner to the two lenses for showing Newton's concentric colored rings. To the tube is fitted a short tube with a stop-cock attached; to the end of this tube a condensing syringe is fixed, and the cavity between the glasses filled with turpentine, varnish, bleached oil, or any other suitable substance of a high refractive power. When the glasses have attained the requisite degree of curvature, the stopcock may be shut, the syringe screwed off, and the fluid lens (for such in reality it is) mounted for use. (Chemist, iii. 50.)

BUTTER. *Qual., &c.* This article is perhaps

employed for this purpose with advantage. It is only necessary to mix the flour up with the jelly, instead of mere water, to add yeast and salt, and to bake in the common way. Dr. Percival has recommended the addition of salep for this purpose. 1 oz. of salep dissolved in 1 quart of water; 2 lbs. of flour; 80 grains of salt, and 2 oz. of yeast, gave 3 lbs. 2 oz. of good bread; but the same weight of materials, without the salep, gave only 2¾ lbs. If too much salep be added, however, it will give its flavor to the bread.

BREAD, WHITING'S, (PATENT.) This is made by dividing the dough into two portions; to the one a little carbonate of soda is added, to the other, a little dilute muriatic acid; they are both well kneaded separately, then mixed together, formed into loaves, and baked immediately. No yeast is used.

BREATH, FŒTID. Scarcely any thing is more disagreeable or disgusting than a stinking breath. Various means have been proposed to remove this annoyance, depending principally on the administration of aromatics, which by their odor might smother it for a time; but these require continual repetition, and are liable to interfere with the functions of digestion. The real cause of a stinking breath is either a diseased stomach or carious teeth; when the former is the case aperients should be administered; and if these do not succeed, an emetic may be given, followed by a dose of salts, or castor oil occasionally. When rotten teeth are the cause, they should be removed; or, if this be impossible, they should be kept clean. Dirty teeth often cause the breath to smell. The use of the tooth-brush should be a daily habit. Occasionally rinsing out the mouth with a little clean water, to which a few drops of a solution of chloride of lime, or chloride of soda, has been added, is an effective method. The following lozenges have also been recommended:—

Gum catechu 2 oz.; white sugar 4 oz.; orris powder 1 oz.; make them into a paste with mucilage, and add a drop or two of neroli. One or two may be sucked at pleasure.

BREAKFAST POWDER. *Syn.* RYE COFFEE. DILLENIUS'S DITTO. HUNT'S ECONOMICAL BREAKFAST POWDER. Rye roasted along with a little fat. *Use.* As a substitute for foreign coffee, of which it is one of the cheapest and best.

BREE'S ANTI-ASTHMATIC PLASTER. *Prep.* Simple diachylon 1 oz.; powdered camphor and powdered opium, of each ¼ oz.; sweet oil ½ a teaspoonful. *Proc.* Melt the plaster with the oil, then remove the vessel from the fire, and stir in the powders; spread it on leather before it gets cold. *Remark.* It is better made with only half the above quantity of opium.

BREWING. The art of making beer.

General notice. Before entering on a description of the process of brewing, it will be necessary to notice the apparatus and materials required for its conduct.

The apparatus consists of,

1. *A copper or boiler* capable of holding fully two-thirds of the quantity proposed to be brewed; with a gauge-stick to determine the number of gallons of fluid at any given depth therein. A copper holding about 140 gallons is a convenient size for brewing a quarter of malt.

2. *A mash-tub,* or *tun,* capable of containing rather more than the copper.

3. *One or more tuns, or vessels,* to ferment the beer in.

4. *Three or four shallow coolers* to reduce the wort as rapidly as possible to a proper temperature for fermenting.

5. *One or two copper or wooden bowls,* for bailing, &c.

6. *A thermometer* with a scale reaching from zero to above the boiling point of water.

7. *A suitable number of casks* (clean) to contain the beer.

8. *One or more large funnels, or tunners.*

9. *Two or more clean pails.*

10. *A hand-pump* of a size proportionate to the brewing.

These articles will vary in value from £10 upwards, to many hundreds, according to the extent of the brewing; but the whole of them, necessary for a private family, may be bought for less than the former amount. By proper care they will last for 30 or 40 years, and still be in a useful state. The place where these vessels are kept, and the operations carried on, is called the "*Brewhouse.*"

The materials necessary to brew beer are, *good malt, hops,* and *water,* and a little *yeast.*

The *malt* is bruised or crushed in a mill before brewing, that it may be acted on the more readily by the water. It should not be ground too small, as it would then make the wort thick; the crushed malt may advantageously lie for a few days in a cool situation, by which it will attract a considerable quantity of moisture from the air, and consequently its soluble portion will be the more easily dissolved out by the water used in mashing. Pale malt may be used coarser than amber or brown malt. A bushel of malt should make a bushel and a quarter when ground, and a quarter should yield between 9½ and 10 bushels, the quantity slightly varying according to the degree of bruising it has undergone. On the large scale, malt is ground in crushing mills, furnished with iron rollers; and on a small scale, by wooden rollers or small mills worked by hand. For private brewing, the malt is generally bought ready ground, for convenience sake. (See MALT.)

The hops should be those of the previous season, and for general purposes grown in Kent; but for the finer sorts of malt liquor, East Kent hops should be used; and where it is intended to be kept for some long time, those known by the names of *Country's, Alton's,* or *Farnham Hops* must be employed. The quantity of hops required to a given measure of malt varies from 2 lbs. to 8 lbs. of the former, to 1 quarter of the latter, according to the nature of the brewing. For good strong beer, 4 lbs. or 4½ lbs. is usually sufficient, but when the liquor is very strong, and it is intended to be highly aromatic, and to be kept for a long period, 1 lb. of hops may be used to every bushel of malt, or 8 lbs. to the quarter. Mild porter has about 3 lbs. to the quarter, and weak common beer has frequently only about ¼ lb. of hops to the bushel of malt. A portion of hops is also frequently added to the finer sort of beer, after it is casked, as we shall presently explain.

The water should be *soft* and *clear,* the *yeast sweet* and *good,* and all the vessels and casks both

sweet and *clean*. If this be not the case, with the latter especially, the best brewing in the world will be useless.

PROCESS OF BREWING. This may be divided into

I. *The mashing*. This operation consists in placing the ground or bruised malt in a large tub or "*tun*," known by the name of the "*mash-tun*," macerating it for some time in hot water, and lastly drawing off the wort from a hole in the bottom, over which a bunch of straw, or a strainer, or false bottom, is placed, to prevent the malt passing out along with the liquor. During the process of mashing, a peculiar principle, called by chemists *diastase*, reacts upon the starch also contained in the malt, and converts it first into a species of gum, called by the French chemists "*dextrine*," and then into a species of sugar resembling that produced by the action of sulphuric acid. The greater the quantity of starch converted into sugar in this way, the stronger and finer will be the wort. It therefore becomes a desideratum with the brewer to mash at a temperature that will most fully promote this object. It has been found that the best temperature for this purpose varies from 157° to 160°, but when more than one liquor is used, the first should be something lower than the former, the next may be between the two, and the third may slightly exceed the latter, or be about 165° or 170°. The action of the first mash is merely to extract the sugar contained in the malt already formed; that of the second to convert the starch into sugar by the action of the diastase; the third to fully complete this object, as well as to carry away the remaining portions of extract.

The mashing is usually performed by filling the copper with water, and as soon as it acquires the temperature of 145° in summer, or 167° in winter, 45 gallons are run off into the mash-tun, and 1 quarter of crushed malt gradually thrown in and well mixed by laborious working, until it becomes thoroughly incorporated and no lumps remain; the agitation is then continued for 30 or 40 minutes, when 36 gallons of water from the boiler, at a temperature of 200°, are added, and the whole again well agitated until thoroughly mixed. The mash-tun is now closely covered up, and allowed to stand for an hour or an hour and a half. At the end of this time the tap is set, and the wort is drawn off into the "underback," and generally amounts to about 50 to 52 gallons: 60 gallons of water, at a temperature of 200°, are next added to the mash-tun, previously drained well, and after being well worked, the whole is covered up as before. This mash is allowed to remain for an hour, when it is drawn off, and the malt again drained ready for the third mash. This time only 35 gallons of water are added at 200°, and allowed to stand for ½ an hour, when it is run off in the same manner as before, and the malt allowed to drain. The worts are now ready for boiling.

In some cases only the first and second mash is used for strong beer, and the third kept for table, or as water to mash a fresh quantity of malt with. In Scotland (see SCOTCH ALE) the brewer only mashes *once*, and afterwards washes his malt by frequent showers or "sparges" of water, by which he gets a wort of greater strength in proportion to its quantity. In operating as above, the average or mean temperature of the first mash is 145°, of the second 170°, and of the third 180°. In winter the mean temperature may be reckoned as 6 or 7° lower. A quarter of malt in this way will produce a wort having a specific gravity by the saccharometer of 1·234, or equal to 84 lbs. of extract. (See SACCHAROMETER.)

It is calculated that 32 gallons of the water employed in the mashing remain in the grains after the wort is drawn off.

II. *Boiling*. The wort is next transferred to the copper, and heated to the boiling point as soon as possible. In large breweries where several coppers are employed, the first mash is no sooner run into the underback, than it is transferred to the wort copper, and immediately boiled, and the successive mashings added as soon as drawn off; but in private houses, where there is only one copper, the boiling cannot be commenced until the water for the last mashing is removed. In some cases the worts are brewed separately, thus producing 2 or 3 qualities of beer, viz. *strong ale or stout, beer, and table beer*. No sooner has the boiling commenced than the hops may be added, and the boiling continued for 2 or 3 hours or more. In some breweries the beer is boiled for several hours, and in Belgium it is said that this is even continued for 10 or 12 hours, but too much boiling drives off the flavor of the hops. In general, two hours good boiling will be found sufficient. In small brewings the first wort should be sharply boiled for 1 hour, and the second for 2 hours. But if intended for beer of long keeping, the time should be extended half an hour. The hops should be strained from each preceding wort, and returned into the copper with the succeeding one. Between the boilings the fire should be damped with wet cinders, and the copper door set open.

For small-beer only half an hour is necessary for the first wort, 1 hour for the second, and 2 hours for the third.

It is reckoned that $\frac{1}{6}$ to $\frac{1}{10}$ part of the wort is dissipated in steam during the process of boiling, but this must of course depend altogether on the evaporative power of the boiler and the length of time the boiling is continued.

III. *Cooling*. The boiling being finished, the wort is run off from the copper into the hopback, which is furnished with a strainer to keep back the hops. It is then pumped into large square shallow vessels called "*coolers*," where it is exposed to a good current of air to cool it down to a proper fermenting temperature as quickly as possible. This is of the utmost importance for the success of the brewing. The wort should be laid so shallow as to cool within 6 or 7 hours to the temperature of about 60°. In warm weather, the depth should not exceed 3 or 4 inches; but in cold weather it may be 5 or 6 inches. As soon as the heat has fallen to about 60°, it should be instantly tunned and yeasted.

It is reckoned that by the joint evaporation from the boilers and coolers, there is a loss of about 40 gallons per quarter.

In private families a good way is to bring the wort from the copper in pails, and to pour it into a basket or a hamper, set over the coolers, by which means the hops will be retained, and the beer run through clear.

BOYLE'S FUMING LIQUOR. Hydrosulphuret of ammonia is usually employed and sold for this article, but the liquor prepared by Boyle's process contains an excess of sulphur. (Gay Lussac.) The properties of both are however the same.

Prep. Mix 4 parts of fresh slaked lime; 2 of sal ammoniac, and 1 of sulphur, then submit the mixture to distillation.

BRA GRAS. Tar, black rosin, and the dregs of strained rosin, melted together.

BRAIN CAKES. *Prep.* Clean, wash, blanch, and soak the brains, then beat them up with a little white pepper and salt, a sage-leaf or two, scalded and finely chopped, and the yelk of an egg; make them into small cakes or fritters, and fry them.

BRAN. The husk of wheat which immediately covers the grain, and which is left in the bolting machine. *Use.* It is largely employed by the calico printers, when diffused through hot water, to remove the coloring matter from those parts of their goods which are not mordanted. A handful mixed with a pail of warm water, forms an excellent emollient foot-bath. Infused in water, (*bran tea,*) and sweetened, it forms a popular demulcent, much used in coughs and hoarseness, and, taken in quantity, proves gently laxative. It also forms an excellent manure, and, from containing the ammoniaco-magnesian phosphate, is especially adapted for potatoes. It is frequently mixed with flour and made into bread, by the poorer orders.

BRANDY. *Syn.* Eau de Vie. Aqua Vitæ. Spiritus Gallicus. Brandy-wine. The spirituous liquor obtained by the distillation of wine. When first distilled it is colorless, and only acquires a yellowish tint from the wood of the casks, in which state it is known and sold as pale or white brandy. The deep color that it usually possesses, is imparted to it by adding a little spirit coloring, (burnt sugar or caramel,) and occasionally a little red sanders wood as well, and is intended to imitate the appearance acquired by brandy from great age, when kept in wood. The natural color, however, which the spirit receives from the cask, no matter how long it may have been in it, never exceeds an amber tint, about the common color of pale Jamaica rum; but the public taste has been gradually vitiated in this respect, until only a spirit of a lively and full "*brandy color*" (unless for a pale brandy) will sell.

The brandies most esteemed in England are imported from France, and are those of Cognac and Armagnac, the preference being generally given to the former. The brandies of Rochelle and Bordeaux may be reckoned next in quality, while those obtained from Portugal, Spain, and Italy are very inferior.

The constituents of brandy are alcohol and water, and small quantities of volatile oil, acetic acid, acetic ether, œnanthic ether, coloring matter, and tannin. It is from the presence of the last six of these substances that the spirit derives its distinguishing smell and flavor. The quantity of alcohol present in brandy varies from 48 to 55 per cent. When first imported, it is generally 1 or 2 overproof, but by age its strength is lessened, and by the time it is usually taken from the bond store for sale, seldom exceeds 3 or 4 underproof. From considerable personal acquaintance with the cognac trade, I feel confidence in asserting, that brandies of the best quality seldom exceed proof, and are generally below it, and that it is a common practice in France to add spirit of wine and coloring to raise the strength to any given point desired by the English purchaser, and to charge the same in the invoice; or where the purchaser is not *well acquainted with the subject*, and desires a strong spirit at a low rate, to sell him brandy so mixed as genuine. The very finest brandies average from 5 to 10 u. p., and never exceed about 2 u. p.; they then contain more than ½ their weight of water, and from their boiling point being higher, they come over more highly charged with essential oil, and other volatile and fragrant principles of the grape, and thus possess in a greater degree that peculiar aroma and flavor for which they are so much esteemed. French brandy or wine, distilled at a low temperature in a water bath, yields a very pure and scarcely flavored spirit.

The quality of the brandy imported from France varies considerably from that which is drunk on the continent, principally from its being *prepared*, or, as it is technically termed, "*made up,*" for the London market, which means lowering it by the addition of spirit, coloring, &c. above described. The common strength at which foreign brandy is sold in England is about 11 or 12 u. p., and below 17 u. p. it becomes seizable by the excise. The strength at which it is sold and permitted in trade, is generally 10 u. p., to which it is reduced by adding water, and never less than 12 u. p., unless it be specially agreed upon. In large quantities and from bond, of course the strength depends much upon the age and quality of the spirit. A fine old brandy being, perhaps, 8 or 10 *u. p.*, while one of the last year's vintage of a commoner quality may be as strong as 2 or 1 *u. p.* But these distinctions are familiar to every experienced brandy dealer.

In France there are several varieties of this spirit distilled, which are known by names descriptive both of their quality and source. The "*eau de vie supérieure,*" or *cognac brandy*, is generally obtained from pale white wines, by careful distillation, and is remarkable for its superior flavor. When kept in glass or stone bottles, it is called white cognac brandy, and the same term is also generally applied when it has been kept in casks, but has not been artificially colored; in the latter case, however, it generally acquires a pale amber tint.

The "*eau de vie ordinaire,*" or *common brandy*, is distilled from high-colored white or red wines, and has generally a sp. gr. of 0·948, and varies from 22 to 27 u. p.

The "*eau de vie de marc*" is obtained from the lees of vinegar and other wines, the marc or cake of grapes from which the juice has been pressed, and the commonest red wines, fermented and distilled together by a quick fire, to drive over as much essential oil and flavoring as possible.

The "*eau de vie seconde*" is the weak spirit that passes over after the stronger spirit has been drawn off, and the receiver changed. *It is used* for common drinking, or mixed with other brandy.

The "*eau de vie à preuve d'Hollande*" is brandy about 19° Baume, or sp. gr. ·9420, the common strength at which it is retailed in France, and will stand the "*proof*" or "*bead*"

The "*eau de vie à preuve d'huile*" is the strongest brandy usually drunk; it is about 23° Baume, or sp. gr. ·918; pure olive oil will just sink in it; hence the above term.

The "*eau de vie fort*" is usually prepared by the redistillation of common brandy, keeping the first portion separate. It answers to our spirit of wine. It is made of 12 different strengths, distinguished by names, exhibiting the quantity of water required to reduce the sample to the "*preuve d'Hollande*." The weakest is called cinq-six, or $\frac{5}{6}$, and the strongest trois-neuf, or $\frac{3}{9}$, the difference between the numerator and the denominator being the quantity of water the 3 parts of the former will take to reduce it to the "*preuve*," when it would make 9 parts. Its sp. gr. is about ·839.

The *esprit de vin* is brandy or spirit rectified to 0·890 and upwards.

The general method of distilling brandy in France differs in no important particular from that practised in England, for grain or molasses spirit. Neither are the French workmen more skilful nor more cleanly in their operations than the English. It is the materials alone that, in this case, conduce to the superiority of the product. The quality of the brandy varies with that of the wine from which it has been distilled. Every soil, every climate, every kind of grape, produces a wine possessing some peculiarity confined to itself, and this wine on distillation produces a spirit possessing like distinctions. A large quantity of brandy is prepared in France soon after the vintage, as the juice of the poorer grapes that is unfit for wine is fermented and at once distilled. It is a general rule, in France, to distil only such wines as are unsaleable, as the profits on the wine, sold as such, are much greater than when it is converted into brandy.

THE STRENGTH OF BRANDY may be ascertained in the same way as alcohol, for which purpose Sike's hydrometer is used in England. In France, from the value of spirit being less, it is frequently tested by simpler methods, though great accuracy obtains, in this particular, where necessary.

Pur. Very little perfectly pure French brandy is obtained by the small consumer in England, as it is not only generally lowered a little by the wholesale dealer, but undergoes a like process at the hands of the retailer. The safest method is either to procure it direct from the bond store, without its even entering a private cellar, or to buy of some known respectable party, and to pay a price that will offer no inducement to dishonesty. If this be not done, by all means buy British brandy, which is now made of excellent quality by many of the leading houses, as *Betts*, *Bretts*, *Booth*, and *Grimble*. From the two former a single sealed bottle may be procured at the same price as by the gallon.

The importation of foreign brandy for home consumption amounts to about 1,400,000 gallons a year.

BRANDY, (REDUCED.) I. To 20 gallons of Cognac brandy add 5 gallons of the best British brandy.

II. To 72 gallons of full-flavored French brandy, add 10 gallons of spirit of wine, (58 *o. p.*,) 8 gallons of water, and 1 pint of good coloring. Rummage well up and let it stand until the next day.

Remarks. The above reduction is generally adopted in trade, and is known by the name of "*improving*." But such is the poverty of the palate of the English brandy drinker, that the adulteration is often not suspected, even when it is carried to double the extent of the above, which is generally exceeded in the hands of the retailer. So long, however, as the foreign spirit constitutes about half of the mixture, and was at first of decent quality and age, the infatuated Englishman smacks his lips, and cunningly holding up his glass between the light and his eye, exclaims, "*Ah! this is a drop of the real.*"

BRANDY, (BRITISH.) *Syn.* BRITISH COGNAC. IMITATION COGNAC, &c. From the heavy duty levied on French brandy imported into England for home consumption, it has become a desideratum with the distiller (rectifier) to produce an English spirit of a similar description. For some time the attempt proved quite unsuccessful, but of late years much capital and talent have been embarked in the pursuit, and the result has proved very satisfactory. An article of British manufacture may now be purchased, at a very reasonable rate, of really respectable quality, and possessing much of the flavor and aroma of foreign brandy, while, as a beverage, it is equally wholesome. Much of the British brandy, however, that is commonly met with, is of such a wretched quality as to be quite undeserving of the name, which is evidence of the fact, that much skill and experience is required to ensure success in its manufacture. For a long time this liquor was distilled from spoilt wine and dregs of wine, both British and foreign, mixed with beer bottoms and similar articles; and when, instead of these, corn, malt, and molasses spirit were employed, it was considered as an unpardonable and wicked misuse of those articles. Modern experience has proved, however, that perfectly pure and tasteless malt spirit is the best article to form into an imitation brandy.

The following formulæ, by skilful management, will produce very good brandy, but it must be recollected that much depends on the quality of the materials employed, as well as on the operator. As the strength and quality of the ingredients, and the methods of manipulation vary, so will the result; much must therefore be left to the judgment and discretion of the artist. It offers a profitable pursuit to the ingenious and industrious chemist and rectifier.

Prep. I. Take 12 gallons of the finest flavorless malt spirit at proof, (or if of a different strength a proportionate quantity;) add thereto 5 gallons of water, $\frac{3}{4}$ lb. of the best crude red tartar or winestone, previously dissolved in 1 gallon of boiling water; $\frac{1}{4}$ pint of acetic ether; 2 quarts of good French wine vinegar; 7 lbs. of bruised French plums, and 1 or 2 gallons of wine bottoms or flavor stuff from Cognac, mix them in a fresh-emptied sherry cask, and let them stand together for 14 days, frequently rummaging up the liquor with a stick; next draw over 15 gallons of the mixture from a still furnished with an agitator. Put the rectified spirit into a clean, fresh-emptied Cognac brandy cask, and add thereto $\frac{3}{4}$ pint of tincture of catechu, 1 lb. of fresh and clean oak shavings, and about a pint of good spirit coloring. Bung close, and agitate occasionally for a few days. *Remarks.* Age improves the above article, and renders it

"Metallic spoons are used when the substance to be examined is intended to be exposed to the action of heat only, and might undergo some change by immediate contact with the charcoal. When the spoon is used, the flame of the blowpipe should be directed to that part of it which contains the substance under examination, and not be immediately applied to the substance itself. The handle of the spoon may be inserted into a piece of charcoal; and if a very intense heat is required, the bowl of the spoon may be adapted to a hole in the charcoal. Small portions may be taken up by platina forceps. Salts and volatile substances are to be heated in a glass tube closed at one end, and enlarged according to circumstances, so as to form a small matrass."

When the behavior of the substance has been observed in this way, it is melted with various fluxes, as microcosmic salt, borax, &c., and their action examined, both in the interior and exterior flame, by which means its composition may be generally ascertained, by reference to any work on mineralogy.

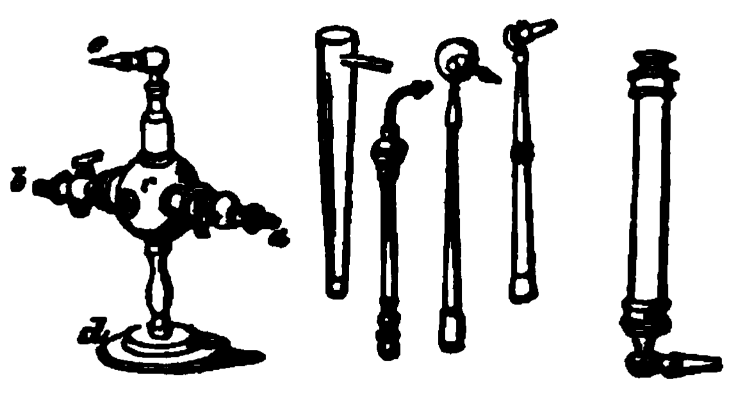
Beginners are usually unable to maintain a continual stream of air from the jet, which is, however, very simple to accomplish. The operation depends upon a little artifice in blowing through the pipe, which is in reality more difficult to describe than to acquire. "The effect intended to be produced is a continual stream of air for many minutes, if necessary, without ceasing. This is done by applying the tongue to the roof of the mouth, so as to interrupt the communication between the mouth and the passage of the nostrils; by which means the operator is at liberty to breathe through the nostrils, at the same time that by the muscles of the lips he forces a continual stream of air from the anterior part of the mouth through the blowpipe. When the mouth begins to be empty, it is replenished by the lungs in an instant, while the tongue is withdrawn from the roof of the mouth, and replaced again in the same manner as in pronouncing the monosyllable *tut*. In this way, the stream may be continued for a long time without any fatigue, if the flame be not urged too impetuously; and even in this case no other fatigue is felt than that of the muscles of the lips." (Ure.)

For producing extreme degrees of heat, the flame is blown with a jet of oxygen gas, and the instrument is then called an "*oxygen blowpipe;*" or a mixture of oxygen and hydrogen is burned, when it is called an "*oxy-hydrogen*" blowpipe. The heat produced by the last is so great that no substance can stand before it. The most refractory native compounds, as rock crystal, quartz, flint, chalk, plumbago, &c., are immediately fused. Gold is volatilized, and iron is rapidly consumed the instant it is placed in the flame. To use this wonderful instrument with safety, and to prevent an explosion, a peculiarly constructed jet is required. The principal blowpipes in general use are figured in the accompanying engravings. The shape of the common blowpipe adopted by the experimentalist may depend upon the fancy of its employer.

This apparatus is also furnished with valves and springs.

Beside the following there are several other va-

1 2 3 4 5 6



1, Oxy-hydrogen blowpipe.
2, Black's do.
3, Bergman's do.
4, Pepy's do.
5, Wollaston's do.
6, Hemming's safety jet for the oxy-hydrogen ditto.

a, Pipe conveying oxygen gas.
b, Do. do. hydrogen gas.
c, Ball stuffed with fine wire gauze.
e, Jet, (internal diameter 1-80th of an inch.)

rieties of blowpipes, in which the air is expelled by the pressure of a column of water, (hence called "*hydrostatic blowpipes,*") or the flame blown with the vapor of boiling alcohol, ("*spirit blowpipe.*")

Use. The blowpipe is of most extensive application in qualitative analysis, especially of minerals, and its use cannot be too highly recommended to the young chemist.

For further information on this subject the reader is referred to Gahn on the Blowpipe; to Ure's Dictionary of Chemistry; to Campbell's Translation of Kobell's Instructions for the Discrimination of Minerals; and to the Chemist, iv. 462.

BLUBBER. This substance, which is so plentiful on some parts of the coast of England, forms a very rich manure for pasture and arable land, when used at the rate of 1 ton to every 20 or 30 loads of mould, together with a chaldron of lime per acre. It must be well turned over, and after lying 3 or 4 months the land will be in prime condition.

BLUE, CHARCOAL. *Prep.* Triturate carbonized vine stalks with an equal weight of potash, then put it into a crucible and place it over the fire, until the mixture ceases to swell, keeping it well stirred all the time; next allow it to cool, dissolve it in water, and saturate the excess of alkali with dilute sulphuric acid; the liquid becomes blue, and a dark precipitate falls down, which turns of a brilliant blue color when dried and heated.

BLUE, COBALT. *Prep.* I. Dissolve Zaffre 1 lb. in ¾ lb. of nitric acid, diluted with an equal weight of water, by digestion for some hours, evaporate nearly to dryness, then dissolve in warm water, filter and add a solution of phosphate of soda as long as any precipitate falls down; collect this on a filter and wash it with cold water, then mix it while still moist with 8 times its weight of freshly precipitate hydrate of alumina, also well washed and still moist. Stir them together until dry; lastly, expose the mixture to a cherry red heat in a crucible, after which cool the mass, and reduce it to a fine powder.

II. Precipitate a solution of nitrate of cobalt as above, and proceed as before.

III. Make a strong solution of neutral nitrate

of cobalt, and mix it with pure moist alumina, then dry it and proceed as before.

IV. Precipitate a solution of nitrate of cobalt with ammonia alum, collect the precipitate, wash, dry, and heat it to a cherry red as before.

Use. A beautiful blue pigment, very permanent.

BLUE, CHEMIC. *Syn.* SAXON BLUE. LIQUID BLUE. SULPHATE OF INDIGO. *Prep.* I. Indigo 1 lb.; oil of vitriol 8 lbs. *Proc.* Put the acid into an earthenware pan, placed in a tub of water to keep it cool, and add the indigo, previously reduced to fine powder, in small successive portions, carefully stirring to prevent it *heating.* When all the indigo has been added, cover up the vessel and let it stand for 4 hours, occasionally stirring it during the time; lastly, dilute it with an equal weight of water.

II. Indigo 1 oz.; oil of vitriol 4 oz.; dissolve as before; the next day add 1 oz. of dry potash; let it stand a day longer, then dilute it with 12 oz. of water.

Use. In dyeing greens and blues, either without preparation or with a mordant of alum and tartar.

BLUE, CHINA. *Syn.* ROYAL SMALTS. *Prep.* Grind together oxide of cobalt or zaffre, with an equal weight of potash, and 8 times its weight of feldspar. Then submit the mixture to fusion in a crucible. *Use.* To paint pottery, and as a pigment.

BLUE, IRON. *Prep.* Precipitate a filtered solution of protosulphate of iron, with another of phosphate of soda. Collect the powder, wash and dry it. *Use.* A lively sky-blue.

BLUE, MOLYBDENUM. *Prep.* Dissolve sulphuret of molybdenum in nitric acid, then add some tin filings and a little muriatic acid. After digestion for some time, pour off the clear and evaporate to dryness. Mix the powder thus obtained with moist hydrate of alumina, as in making cobalt blue, and heat it to nearly a dull red.

BLUE, MOUNTAIN. Carbonate of copper, mixed with earthy matter.

BLUE, SAXON. *Prep.* Dissolve 1 oz. of sulphate of iron and 8 oz. of alum in 1 gallon of water, then add simultaneously, separate solutions of prussiate of potash and common pearlash, until they cease to produce a precipitate; lastly, allow the liquid to deposite, decant the clear portion, wash the remainder well with water, and dry it. Or a solution of the sulphate of iron may be first made and precipitated with the prussiate of potash, and instantly mixed with the solution of alum and a solution of pearlash, added until it ceases to produce a precipitate.

BLUE, SUPERB LIQUID. *Prep.* Put into a small matrass or common vial 1 oz. of pure Prussian blue reduced to powder, and pour over it from 1½ oz. to 2 oz. of concentrated muriatic acid. The mixture produces an effervescence and the prussiate soon assumes the consistence of thin paste. Leave it in this state for 24 hours, then dilute it with 8 or 9 oz. of water, and preserve the color thus diluted in a bottle well stopped.

The intensity of this color may be lessened, if necessary, by new doses of water. If the whole of this mixture be poured into 1 quart of water, it will still exhibit a color sufficiently dark for washing prints.

BLUE, STONE. *Syn.* FIG BLUE. THUMB BLUE. KNOB BLUE. CROWN BLUE. MECKLENBURG BLUE. QUEEN'S BLUE. *Prep.* Mix finely powdered indigo with starch paste until a proper color be produced, then make it into small lumps. II. Instead of starch use whiting and a little weak size. *Use.* Employed by laundresses to give a faint blue tinge to linen.

BLUE DYE. *Proc.* First give the goods a mordant of alum, then rinse them well and boil them in a bath of logwood, to which a small quantity of blue vitriol has been added.

II. Boil in a bath of logwood, then add 1 oz. each of tartar and verdigris to every pound of logwood employed, and boil again.

III. Bilberries, elder-berries, mulberries, privet-berries, and several other vegetable blue substances, may be used to dye blue as above instead of logwood.

Remarks. By increasing the proportion of alum the color verges on purple, and by employing a little acetate of iron or green copperas, the darker shades are produced. Verdigris, blue vitriol, and alkalis turn it more on the blue, and a mordant of tin imparts a violet cast. None of these dyes, however skilfully managed, are so permanent as those produced with indigo and Prussian blue. (See INDIGO, PRUSSIAN BLUE, and DYEING.)

BOARDS, MARBLE, &c., TO TAKE OIL AND GREASE OUT OF. I. Make a paste with fuller's earth and hot water, cover the spots therewith, let it dry on, and the next day scour it off with soft or yellow soap.

II. Make a paste with soft soap, fuller's earth, and a little pearlash, and use it as above.

III. Make a paste of fresh slaked lime, water, and pearlash, and use it as above. *Remarks.* Observe not to touch the last mixture with the finger, as it is very caustic unless it be largely diluted with water.

BOERHAAVE'S RULES FOR PRESERVING HEALTH.

"Keep the feet warm;
The head cool; and
The body open."

These rules are very concise, and convey directions which, though valuable, are too often neglected.

BOILING POINT. The boiling point of water may be raised considerably above 212° Fahr. by the addition of saline matter. Thus, 60 parts of dry acetate of soda added to 40 of water raise the boiling point to 256° Fahr., and 30 parts of muriate of soda added to 70 of water raise it to 224 Fahr. As in practice, however, it proves inconvenient to employ a saturated solution for a bath, from the evaporation of the water continually inducing the salt to crystallize, it is usual to keep it considerably below that point. By means of such solutions the chemist is enabled to evaporate fluids and desiccate solids at any required temperature. The boiling point of baths containing different salts may be seen below.

TABLE of the Boiling Points of several Saline Solutions, abridged from the Table of Mr. T. GRIFFITHS. (Jour. Science, xviii. 89.)

Names of Salts.	Dry Salt in 100.	Boiling Point.
Acetate of soda, . . .	60	256° F.
Nitrate of soda, . . .	60	246
Rochelle salt, ...	90	240
Nitre, ...	74	238
Muriate of ammonia, .	50	236
Tartrate of potash, . .	68	234
Muriate of soda, . . .	30	224
Ditto, ...	20	218·75
Muriate of lime, . . .	40	216·5
Sulphate of magnesia, .	57·5	222
Supersulphate of potash,	?	222
Borax, ...	52·5	222
Phosphate of soda, . .	?	222
Carbonate of soda, . .	?	220
Muriate of baryta, . .	45	220
Alum, ...	52	220
Sulphate of potash, . .	17·5	215
Bitartrate of potash, .	9·5	214
Sulphate of soda, . .	31·5	213

Remarks. From 5 to 9 degrees are usually lost by passing through the vessel, depending on its thickness and materials. The boiling point of water in glass vessels, under common circumstances, varies from 212·54° to 215·6°, and in perfectly pure and smooth glass vessels, water may be heated to 221° F. without boiling. (M. F. Marcet.)

BOILS. *Treat.* When these appear, suppuration should be promoted by poultices of bread and linseed meal, to which a little fat or oil may be added, to prevent their getting hard. When poultices are inconvenient, exposure to the vapor of hot water, or the application of stimulating plasters, may be adopted instead. When sufficiently ripe, the matter should be evacuated, and the wound dressed with a little simple ointment spread on a piece of clean lint or linen. The diet may be full and liberal until the maturation of the tumor and the discharge of the matter, when it should be lessened, and the bowels opened by some saline purgatives, as salts or cream of tartar. When there is a disposition in the constitution to the formation of boils, the bowels should be kept regular, and tonics, as bark or steel, taken, with the frequent use of sea-bathing, if possible.

BOLAS. *Prep.* Into 2 lbs. of flour pour ¾ pint of warm milk, a small teacupful of yeast, and 6 eggs; make them into a dough, add 1 lb. of butter, by degrees, and let it rise for 1 hour, then mix in 1 lb. of powdered sugar, and make the mass into cakes; put these into cups or tins previously well buttered, and ornament the top with candied orange or lemon peel; lastly, bake them.

BOLUS OF ALUM. *Prep.* Powdered alum and conserve roses, of each 15 grs.; sirup of orange peel or saffron to mix. *Used* in fluxes, &c.

BOLUS OF MUSK. *Prep.* I. Musk 15 grs.; camphor 5 grs.; powdered gum 3 grs.; mix with sirup of saffron. *Use.* In convulsions and typhus fever.

II. Musk and carbonate of ammonia of each 10 grs.; conserve of roses q. s.; to make a bolus. *Use.* Sometimes given every three hours in mortification accompanied with spasms.

BOLUS, PURGING, (FOR DOGS.) *Prep.* Jalap and rhubarb, of each 15 grs.; ginger 4 grs.; soap 10 grs.; water q. s.; if this does not open the bowels, add aloes half a drachm, or 3 or 4 grs. of calomel. *Use.* In the distemper; it must be preceded by copious bleeding, and abstinence from food for a day or a night.

BOLUS OF SULPHATE OF ZINC. *Prep.* Sulphate of zinc 20 to 25 grs.; conserve of roses q. s. to make a bolus. *Use.* As an emetic where poison has been taken, to be followed by copious draughts of warm water or weak tea.

BOLETIC ACID. An acid discovered by Braconnot in the juice of the boletus pseudo-igniarius.

Prep. Concentrate the expressed juice to a sirup by means of a gentle heat, then digest it in strong alcohol, and dissolve the residuum in water; add a solution of nitrate of lead as long as any precipitate falls, which must be washed with water, diffused through water in a tall glass vessel, and in this state a current of sulphureted hydrogen must be passed through it, until the lead is thrown down; filter, evaporate, and crystallize; lastly, purify by resolution and crystallization from alcohol.

Remarks. This acid dissolves in 45 parts of alcohol and 180 of water, and is volatile. It is doubtful whether it be a distinct acid principle.

BOLOGNA VIAL. The bologna, or philosophical vial, is a small vessel of glass which has been suddenly cooled, open at the upper end, and rounded at the bottom. It is made so thick at the bottom that it will bear a smart blow against a hard body without breaking; but if a little pebble, or piece of flint, is let fall into it, it immediately cracks, and the bottom falls into pieces; but unless the pebble or flint is large and angular enough to scratch the surface of the glass, it will not break.

BOLOGNIAN PHOSPHORUS. *Syn.* BOLOGNIAN STONE. This is a phosphorescent stone that once excited great attention. It was accidentally discovered by a shoemaker of Bologna in the 17th century. A family of the name of Logani, who were very successful in making it, acquired a large fortune by selling it to the curious throughout Europe.

Prep. Powder native sulphate of baryta that has been previously ignited, and make it into a paste with mucilage of gum arabic; roll this into pieces a quarter of an inch thick, and dry them in a moderate heat; then expose them to the heat of a wind furnace by placing them loose among the charcoal.

Prop., Use, &c. Placed in a vial and exposed for a few minutes to the sun's rays, it will give light enough in the dark to see the figures on the dial-plate of a watch.

BOMBIC ACID. An acid which M. Chaussier extracted from the silkworm in 1781. It has since been found not to be a distinct acid.

BON-BONS. *Prep.* Provide leaden moulds, which must be of various shapes, and be oiled with oil of sweet almonds. Take a quantity of brown-sugar sirup in the proportion to their size, in that state called a *blow*, which may be known by dipping the skimmer into the sugar, shaking it, and

blowing through the holes, when parts of light may be seen; add a drop of any esteemed essence. If the *bon-bons* are preferred white, when the sugar has cooled a little, stir it round the pan till it grains, and shines on the surface; then pour it into a funnel and fill the little moulds, when it will take a proper form and harden: as soon as it is cold take it from the moulds; dry it for two or three days, and put it upon paper. If the *bon-bons* are required to be colored, add the color just as the sugar is ready to be taken off the fire.

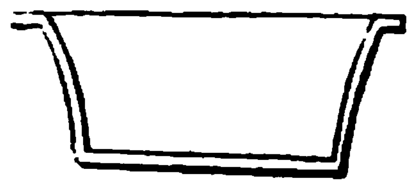
BONES. The bones of animals are employed for various purposes in the arts, manufactures, and domestic economy. (See the succeeding articles.)

BONE ASH. *Syn.* IMPURE PHOSPHATE OF LIME. *Prep.* Calcine bones to whiteness, and reduce the ash to fine powder. *Use.* To make pure phosphate of lime, and to form cupels. It is sold for burnt hartshorn.

BONE BLACK. *Syn.* ANIMAL CHARCOAL. IVORY-BLACK. Bones burnt in close vessels.

Prep. On the large scale, two different processes are adopted to produce bone black.

I. (*From bones as the sole product.*) The bones broken to pieces are put into small cast-iron pots of the shape of the engraving, and varying from



$\frac{1}{4}$ to $\frac{1}{2}$ an inch in thickness. Two of these being filled, are dexterously placed with their mouths together and then luted with loam. A number of vessels, thus prepared, are placed side by side and over each other, in an oven resembling a potter's kiln, to the number of 100 to 150. The fire is then kindled, and the heat kept up strongly for 10 or 12 hours, according to circumstances, until the process is completed. The whole is allowed to cool before opening the pots.

II. (*The residuum of the manufacture of Bone Spirit.*) The bones are here introduced into retorts similar to those used at the gas works, and heat being applied, the volatile products are conveyed away by iron pipes to cisterns where its condensable portion is collected. As soon as the process of distillation is finished, the solid residuum in the retorts, while still red hot, is removed through their lower ends into wrought-iron canisters, which are instantly closed by air-tight covers, and luted over. These are then raised to the ground by a crane and allowed to cool.

Remarks. Previously to distillation or calcination, the bones are boiled for their grease, which is sold to the candle and soap makers. They are then sorted, the finest pieces being selected for making handles for knives, tooth-brushes, buttons, &c.; the next sort for making into bone black; while the smallest and worst description is reserved for grinding into manure. The bones lose about $\frac{1}{2}$ their weight by the process of burning. After this they are ground in a mill, sorted by sieves into two kinds, one *granular*, somewhat resembling gunpowder, and the other *quite fine.* The one is sold under the name of *animal charcoal*, for decoloring liquors, the other as a *pigment.* This article possesses the valuable property of taking lime from sirups, at the same time that it decolors them. Its power as a decolorizer may be tested by adding it to a solution of brown sugar or molasses, or water containing $\frac{1}{1000}$ part of indigo dissolved in sulphuric acid. The test should be made in a small glass tube. By well washing and careful reburning, this charcoal may be used any number of times as a decolorizer.

BONES AND IVORY, DYES FOR. 1. (*Red.*) *a.* Make an infusion of cochineal in water of ammonia, then immerse the pieces therein, having previously soaked them for a few minutes in very weak aquafortis and water.

b. Boil the bones with 1 lb. of Brazil dust, in 1 gallon of water, for 3 hours, then add $\frac{1}{4}$ lb. of alum and boil for 1 hour more.

2. (*Black.*) *a.* Immerse the pieces in a weak solution of nitrate of silver, for a short time, then expose them to the sunlight.

b. Steep for 2 or 3 days, in a decoction made with 1 lb. of galls and 2 lbs. of logwood, then steep for a few hours in iron liquor, (acetate of iron.)

3. (*Green.*) *a.* Steep in a solution of verdigris to which a little aquafortis has been added.

b. Dissolve distilled verdigris in weak vinegar, and steep the pieces therein.

c. Steep in a solution of 2 parts of verdigris, and 1 of sal ammoniac. *Observe* not to use a metallic vessel for the above.

4. (*Purple.*) *a.* Steep in a weak solution of terchloride of gold.

b. Boil for 6 hours in a decoction of 1 lb. of logwood in $\frac{1}{2}$ gallon of water, adding more water, as it wastes by boiling, then add 2 oz. of alum, and boil for 1 hour more.

5. (*Yellow.*) *a.* Boil for 1 hour in a solution made with 1 pound of alum in 1 gallon of water, then take out the pieces and steep them in a decoction made with $\frac{1}{2}$ lb. of turmeric in 2 quarts of water; lastly, mix the two liquors and boil them therein for 1 hour.

b. Steep the pieces for 24 hours in a solution of sugar of lead, then take them out, and when dry, immerse them in a solution of chromate of potassa.

c. Dissolve as much of the best orpiment in water of ammonia or hartshorn, as it will take up, then steep the pieces therein for twenty-four hours; lastly, take them out and dry them, when they will turn yellow. *Remark.* By diluting the solution with water, any shade of yellow may be made.

6. (*Blue.*) *a.* Stain them green, then steep them in a hot and strong solution of pearlash.

b. Boil them in a strong decoction of logwood, and afterwards steep them in a solution of blue vitriol.

c. Steep them for a short time in a weak solution of sulphate of indigo, to which a little salt of tartar has been added; or, still better, boil them in a dyer's green indigo vat. *Remarks.* The bones of living animals may be dyed by mixing madder with their food. The bones of young pigeons may thus be tinged of a rose color in 24 hours, and of a deep scarlet in 3 days; but the bones of adult animals take a fortnight to acquire a rose color. The bones nearest the heart become tinged soonest. In the same way extract of logwood will tinge the bones of young pigeons purple. (Mr. Gibson.)

BONE GREASE. *Prep.* By bruising and boiling the refuse bones of the kitchen, and skimming the broth when cold, from $\frac{1}{4}$ (?) to $\frac{1}{3}$ of their

weight of good fat may be obtained, fit for culinary purposes when fresh, but always excellent for making soap and candles. (Proust.)

BONE GLUE. *Syn.* GELATINE. *Prep.* This is made by dissolving out the earth of bones, previously boiled for the grease, washing the remaining jelly with water, then boiling it with a little water, and forming it into cakes for sale. (SEE GLUE.)

BONE MANURE. For this purpose the bones are ground to a coarse powder in a mill, and sowed along with the seed in a drill. It is said that wheat thus treated yields 30 to 50 per cent. more in weight of straw and grain than by the common methods. It is usually applied to light or turnip soils, which it renders more than ordinarily productive. Bone manure is much used in the west of Yorkshire, Holderness, and Lincolnshire. The usual quantity per acre is 70 bushels, when used alone; but when mixed with ashes, as common manure of any sort, 30 bushels per acre is thought quite enough. It is applied at the same periods as other manure, and has been found in this way to remain 7 years in the ground. The rough part of this manure, after being 5 years in the ground, has been gathered off one field and thrown upon another of a different soil, and has proved, even then, good manure.

BONES, (IN COOKERY.) The bones of good meat form most excellent materials for making soups and gravies, as is well known to every good cook. In France, soup is extensively made by dissolving bruised bones in a steam heat of 2 or 3 days' continuance, and also by dissolving out the earthy part by digestion in weak muriatic acid, when a lump of gelatine is obtained, which after being well washed with water will dissolve by boiling, and is equal to isinglass for all the purposes of making soups and jellies. Proust has recommended the following process for making the best of bones, in hospitals, jails, and similar establishments:—Crush the bones small, then boil them for 15 minutes in a kettle of water, cool, and skim the fat off, which varies from $\frac{1}{8}$ to $\frac{1}{4}$ (?) of the weight of the bones employed, and when fresh is fit for all common purposes. The bones are then ground, and boiled in 8 to 10 times their weight of water, of which that already used must form a part, until $\frac{1}{2}$ is wasted, when a very nutritious jelly is obtained. A copper vessel should not be used, as the jelly acts upon this metal. An iron Papin's digester is the most suitable. The bones of boiled meat are nearly as productive as those of fresh meat, but roasted meat bones scarcely afford any jelly. (Dr. Young.) As boning meat before cooking is now a very general practice, a quantity of fresh bones may always be had.

BONE SHAVINGS. *Syn.* BONE DUST. BONE TURNINGS. These yield a beautiful jelly by boiling with water, nearly equal to that produced from hartshorn shavings, for which they are very frequently sold.

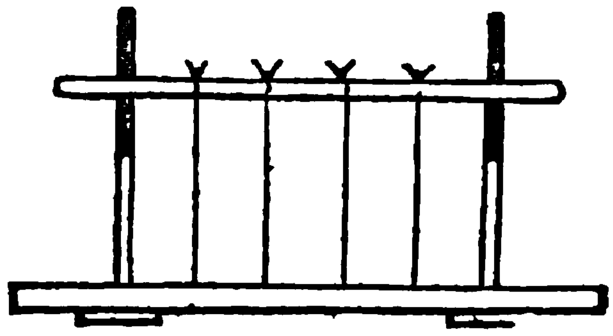
BOOKBINDING. The process of binding books may be divided into several distinct operations, which, in large establishments, are usually performed by different persons, such a method being found to produce greater expedition and better work, than when the whole is done by one person.

The sheets received from the hands of the printer are—

1. *Folded*, which is done correctly by observing the marks or catchwords at the bottom of the pages. As the sheets are folded they are laid upon each other in proper order, and are ready to undergo—

2. *The operation of beating.* This is performed by laying them upon a large stone, and striking them with a heavy smoothed-faced hammer, or by passing them through a rolling press. The former method is usually adopted in the small way, and the latter on the large scale.

3. *The sheets are next fastened to bands*, which is done by taking the folded sheets up one by one, and sewing them to pieces of cord, stretched in a little frame screwed or fastened to the counter or table, called the sewing-press. (See eng.) The



number of bands used, is generally 6 for a folio, 5 for a quarto, and so on proportionally, less than 4 seldom being employed even for small sizes. The ends of the cords being cut off to within about 2 inches of the back, the sheets are ready for—

4. *Glueing.* The back being knocked into shape with a hammer, and the sheets placed in the cutting press, which is then slightly screwed up, melted glue is thinly and evenly applied. After a short time the book is removed from the press, and the back properly adjusted with a hammer, when it is again put into the cutting press, where it is screwed up very tight, and is then ready for—

5. *Cutting.* The instrument employed for this purpose is of a peculiar shape, and called a plough or plough-knife.

6. *Affixing the boards. The bands*, are now scraped out fine at the ends, and the pasteboard to form the covers is fastened thereto, and is then properly adjusted, and shaped with a large pair of shears. The edges now undergo the operation of—

7. *Sprinkling*, or other adornment. The first is performed by a stiff brush of hog's bristles, dipped in the color; the brush being held in the one hand, and the hairs moved with the other.

8. *The external covering of leather, fancy cloth, or paper*, is now applied, having been previously well soaked in paste, to make it properly adhere. One or more of the blank leaves of the book are next pasted against the inside of the cover, to screen the ends that are turned over, when the book is finished; or for choice work, is handed to a "*finisher*" for—

9. *Lettering, gilding, &c.* Gold-leaf is applied by means of white of egg, the pattern being given by pressure with heated brass tools, having the design or letters on their surfaces. The whole is then glazed over and polished.

Remarks. The succession of some of the above operations sometimes varies with the workmen and

the nature of the binding. The above must therefore only be regarded as a short and general outline of the process. If the reader will accompany the perusal by an examination of a bound book, the whole will be rendered quite familiar.

The following varieties of binding may be noticed:

a. Boards. A book, loosely done up without cutting the edges, and covered with paper or cloth, is said to be in boards.

b. Cloth-binding. This style of binding is that in which the majority of works are now issued. It admits of great neatness and even beauty, and is very durable and cheap. *Proc.* The prepared cloth, cut by a pattern to the size suited to the volume, is passed rapidly through a rolling press, between engraved cylinders of hardened steel, which print the pattern in relief. Paste is now applied to the cloth, when it is placed over the volume, previously prepared to receive it. Books in cloth-binding are not commonly cut at the edges, unless highly finished.

c. Dutch binding. This species of binding is distinguished by the backs being of vellum.

d. French binding. This consists in pasting a piece of parchment over the back of the book, between each band, and pasting the ends upon the inside of each cover.

e. Half-binding. Books forwarded in boards, and finished with leather backs and corners, are called "*half-bound.*"

f. Hancock's patent binding. In this method the sheets are folded in double leaves, and being properly placed together and adjusted, the book is subjected to the action of a press, and a strong solution of Indian rubber is smeared over the back with the finger. The operation is repeated, as often as necessary, when fillets of cloth are cemented on with the varnish, and the book is ready to have the boards attached. Thus several of the common operations of binding are dispensed with. I willingly bear testimony to the strength and durability of this method, and the great convenience it affords in allowing the books to open perfectly flat upon a table, or to be distorted in any possible manner, without injury to their backs. It is the best way of binding books for travellers. I once had a large trunk of books, among which was one bound on Hancock's plan. All the rest were nearly torn to pieces by a few months' journey, but this one was uninjured.

g. Law binding. A strong method applied to law books.

h. Leather binding. *Proc.* Immerse the leather in water; after which wring it, and stretch it on a board; place the book with the boards extended thereon, and cut out the cover, allowing about half an inch larger than the book, to turn over the inside of the pasteboards. Pare the edges of the cover very thin all round on a marble slab, and paste it well; glue the back of the book, and spread the cover on the board.

Let the pasteboards be properly squared and even; put the book on the cover, which draw on very tight. Rub the cover smooth with a folding-stick, and turn it over on the inside of the pasteboards on the fore edge. The corners on the inside must be cut and neatly pressed down; tie a piece of thread round the book, between the boards and head-bands, draw up the leather on the back, if necessary, to cover the top of the head-bands; rub the back very smooth with a flat folding-stick, and place it at a distance from the fire to dry.

Rough calf must be damped on the grain side with a sponge and water before pasting and covering.

Russia leather must be well soaked in water fo an hour, taken out, well beaten, and rubbed; afte which the paste must be well worked into the flesl side before covering.

Morocco must be grained by rubbing it on a board, with the grain side inside, and after being pasted, left to soak for a quarter of an hour, and the cover then drawn on with a piece of woollen cloth to preserve the grain.

Roan may be either soaked in water or left to soak when pasted.

i. Italian binding. This is a common variety of binding employed in Italy, (hence its name,) in which the books are covered with a kind of thick coarse paper. In Italy it is called "*alla rustica.*"

k. Marble binding. Named from the design of the exterior.

l. Palmer's patent binding. This consists in applying small brass bars, linked together, to the back of the book, in such a manner that they make the different sections of the book, when open, parallel with each other, and thus admit of writing, without inconvenience, on the ruled lines near the back.

m. School binding. The following is a strong method for school books:—When the books have been cut, colored, and backed, cut off the part of the bands intended to be laced to the pasteboards, and glue on the back a piece of strong smooth linen cloth, which must reach within half an inch of the head and foot, turning on the sides about an inch; paste the boards on each side of the cloth, fixing them close in at the groove, and give the books a firm pressing in the standing-press till dry. Square the boards, glue the backs, and cover and finish in the usual manner.

This method will secure and give strength to the joints, so as effectually to prevent the leather from breaking, and require no more time than lacing in the bands. The edges may now be colored, sprinkled, or marbled, as required.

n. William's patent binding. This consists in placing a back, of a curved form, turned a little at the edges, and made of iron, copper, brass, wood, ivory, or any other material of sufficient firmness. This back is adjusted to the book before it is bound, in such a manner that it may just cover, but not press upon the edges, and is fastened on by enclosing it in vellum or ferret wrappers, which are pasted down upon the boards or drawn through them. The effect is, to make the book open evenly and freely, and to prevent it from spreading on either side.

BOOTS, TO CLEAN. To do this in the best style always use "boot-trees," employ but little blacking, and brush it off while damp. The dirt should, of course, be carefully brushed off before applying the blacking.

BOOTS AND SHOES, WATERPROOF COMPOSITION FOR. *Prep.* Boiled oil 1 pint; oil of turpentine, black rosin, and bees' wax, of each 3 oz. *Proc.* Melt the wax and rosin, then stir in the oil, remove the pot from the fire, and when it has cooled a little, add the turpentine.

II. Take 3 oz. of spermaceti, and melt it in a pipkin, or other earthen vessel, over a slow fire; add thereto 6 drachms of Indian rubber, cut into slices, and these will presently dissolve. Then add *seriatim* of tallow 8 oz.; hog's lard 2 oz.; amber varnish 4 oz. Mix, and it will be fit for use immediately. *App.* The boots or other material to be treated, are to receive two or three coats, with a common bladking brush, and a fine polish is the result.

BOOT-TOP LIQUID. *Prep.* I. Oxalic acid and white vitriol of each 1 oz.; water 1½ pints. *Proc.* Dissolve and apply with a sponge to the leather previously washed with water, then wash the composition off with water, and dry. This liquid is poisonous.

II. Mix in a vial, 1 drachm of oxymuriate of potass, with 2 oz. of distilled water; and when the salt is dissolved, add 2 oz. of muriatic acid. Then shake well together, mix in another vial 3 oz. of rectified spirit of wine with ½ an oz. of the essential oil of lemon, unite the contents of the two vials, and keep the liquid, thus prepared, closely corked for use. This liquid should be applied with a clean sponge, and dried in a gentle heat; after which, the boot-tops may be polished with a proper brush, so as to appear like new leather.

III. Sour milk 1 quart; gum arabic 1 oz.; juice of 2 lemons; white of 2 eggs; oil vitriol 2 oz. Mix.

IV. Sour milk 1 quart; butter of antimony, cream of tartar, tartaric acid, and burnt alum, of each 2 oz. Mix.

BORACIC ACID. *Syn.* SEDATIVE SALT. SED. SALT OF VITRIOL. SED. SALT OF HOMBERG. *Prep.* Dissolve borax in 4 times its weight of boiling water, then add sulphuric acid to the solution until it acquires a distinct acid reaction, (about ¼ the weight of the borax.) As the solution cools, crystals of boracic acid will be deposited. These crystals must be then placed on a filter, and washed with a little cold water. They may be still further purified by solution in boiling water and recrystallization.

Remarks. Even after this treatment, the crystals are apt to retain a little sulphuric acid or sulphate of soda, which can only be got rid of by heating them in a platinum crucible, before redissolving them and crystallizing the second time, as above described. When wanted perfectly pure for chemical analyses, this plan must be always adopted.

The boracic acid of commerce is extracted from the acid lagoons of Tuscany.

Prep. As thus obtained, this acid is soluble in 25 times its weight of cold, and 3 times its weight of boiling water. Very soluble in alcohol, which then burns with a bright green flame, offering a sure test of the presence of boracic acid. Odorless, and tastes bitter. Reddens litmus, but browns turmeric paper. It was once administered internally in large doses, (by Cullen,) but is now scarcely ever employed as a medicine.

BORATE. A compound, formed of the preceding acid and one of the bases.

Prop. The boracic acid has but a feeble affinity for the bases; most of the borates being decomposed by the stronger acids, the former being liberated in a free state. *Prep.* Many of them may be formed by digestion of the hydrate of the base in a solution of the acid, with the assistance of heat, or by double decomposition.

Tests. I. By digestion in slight excess of oil of vitriol, evaporating to dryness, powdering, and dissolving in alcohol, the latter will acquire the property of burning with a green flame. II. If to a strong and a hot solution of a borate, sulphuric acid be added in excess, crystals of boracic acid will form as the liquor cools.

BORATE OF MERCURY. *Prep.* I. Neutral borate of soda 265 grs.; calomel 222 grs.; grind together in a mortar, with a little water, then fill the mortar up with hot water; collect the red precipitate; wash and dry.

II. Add a solution of borax to a solution of quicksilver in nitric acid. Collect the precipitate as before. (White.)

BORATE OF SODA. I. (*Neutral borate.*) *Prep.* Saturate boracic acid in solution with carbonate of soda, at a boiling heat. (Berzelius.)

II. (*Biborate.*) This salt, often erroneously called borate and subborate, is the borax of commerce, and is a natural production. (See BORAX.)

BORAX. *Syn.* BIBORATE OF SODA. BORATE OF SODA. SUBBORATE OF SODA. REFINED BORAX. Crude borax is a natural production, and after being refined, forms a large portion of the borax of commerce. In its rough state it is called *crude borax, tincal, tincar,* &c. It is found crystallized on the edges and shallows of a brackish lake in Thibet, during the winter. It is also prepared by saturating the native boracic acid of Tuscany with soda. The market being literally overloaded with the former article, its price has fallen so low as to allow of its employment for this purpose with great advantage. A valuable paper on this subject, by M. Payen, appeared in the "Ann. de Chimie et de Phys." for July, 1841; and a translation of the same in "The Chemist," vol. ii. 368, to which the reader is referred for a complete account of this process.

The best Tuscany boracic acid contains only 50 per cent. of real boracic acid, and yields no more than 140 to 150 per cent. of good borax.

Prop., Use, &c. It is extensively employed as a flux for metals, for soldering, and in medicine. Internally it is diuretic, sedative, emmenagogue, and cooling, in doses of 15 to 40 grains; externally as a gargle for sore throat, and in powder as a detergent in aphthæ, and ulcerations of the mouth. Dissolved in rose-water, it is used as a cosmetic, and mixed with 8 times its weight of lard, forms a useful piles ointment.

Tests. These are the same as for the borates, which see. It reddens turmeric paper, and, before the blowpipe, fuses into glass, which may be tinged red by terchloride of gold, and blue by cobalt.

Pur. The purity and strength of borax are best ascertained by determining the quantity of sulphuric acid required to neutralize a given weight, as indicated by litmus paper. Common salt and alum are frequently mixed with borax to lower the value. The former may be detected by dissolving the borax in hot water, when a solution of lunar caustic will give a curdy white precipitate, soluble in ammonia; and the latter by water of ammonia, which will give a bulky white precipitate. The

former must be distinguished from the white pulverulent precipitate of borate of silver, which will be thrown down from pure borax.

BORAX, GLASS OF. *Prep.* Dry borax with a gentle heat, breaking down the froth as it rises, then melt it by increasing the heat until it runs into a glass. *Use.* In soldering, and as a blowpipe flux.

BORO-FLUORIDE OF HYDROGEN.—*Prep.* Pass fluoboric acid gas through water, and afterwards carefully concentrate the solution; cool and separate the crystalline powder from the solution, which is the boro-fluoride of hydrogen. *Prop., &c.* With most of the protoxides it interchanges bases, and metallic boro-fluorides result.

BORO-FLUORIDE OF BARIUM. *Prep.* Add carbonate of baryta to boro-fluoride of hydrogen, until it ceases to be dissolved; evaporate to the consistence of a sirup, when crystals will form. *Remarks.* The boro-fluoride of calcium, magnesium, and lead, may be formed in a similar way.

BORO-FLUORIDE OF POTASSIUM.—*Prep.* Drop boro-fluoride of hydrogen into a solution of carbonate of potassa, collect the white powder that falls, and wash it with cold water.

BORO-FLUORIDE OF SODIUM. *Prep.* Dissolve fluoride of sodium in boro-fluoride of hydrogen, and crystallize. *Remarks.* Boro-fluoride of lithium may also be formed in a similar way.

BORON. The base of boracic acid, discovered by Sir H. Davy, in 1807, by means of the galvanic battery of the Royal Institute.

Prep. Potassium, and perfectly dry boracic acid, or still better, boro-fluate of potassa, intimately mixed together, are to be placed in an adopter, or glass tube, and submitted to a low red heat. When cool, remove the loose cork that fastened its mouth, and pour in successive portions of hot water, until the whole matter is detached and dissolved. Collect the liquid and allow it to settle, then wash the precipitate, first with a solution of sal ammoniac, and finally, with alcohol; next dry the boron in a capsule, and put it into a well-stopped vial.

Prop., &c. A solid, tasteless, and inodorous powder, of grayish-brown color. With sulphur it unites at high temperatures, forming sulphurets; and when placed in chlorine gas it spontaneously inflames, and a gaseous chloride is produced. This gas may also be made by exposing calcined borax and charcoal at a red heat to the action of dry chlorine.

BOTTLE, RED. *Syn.* TAYLOR'S RED BOTTLE. WHITWORTH DOCTOR'S RED BOTTLE. *Prep.* British brandy 1 quart; powdered cochineal ½ oz.; oil of origanum 10 drops. Digest for 24 hours and filter.

BOUGIE. *Syn.* CANDELA. CANDELA CEREA. CANDELULA. VIRGA CEREA. CEREA. CEREOLA. CEREUS. CEREOLUS. A long slender instrument, introduced into the urethra, œsophagus, or rectum, to overcome strictures of those canals. The word bougie is the French for a wax candle.

Prep. I. Add 3 parts of boiled linseed oil to 1 part of melted amber, and when mixed add 1 part of oil of turpentine; spread the mixture at 3 successive intervals upon loose spun silk cord or web, dry in a heat of 150°, and repeat the process until the instrument has acquired the proper size, then polish, first with pumice-stone, and afterwards with tripoli and oil.

Remarks. The above is the original receipt of the French professor Pickel, and is still generally used, slightly modified, on the continent.

II. Add to the oil and amber melted together, as last, caoutchouc in the proportion of $\frac{1}{16}$ of the weight of the oil employed; when dissolved, remove the vessel from the fire and proceed as before.

Remarks. This is the plan usually adopted at Paris, and for the best elastic bougies this process usually occupies from 6 to 8 weeks. When the bougie is wanted to be hollow, a piece of polished metallic wire is introduced into the axis of the silk, or tinfoil is rolled round the wire and the composition applied as before. When dry and hard the wire is withdrawn.

III. (*Caoutchouc, or elastic gum bougies.*) *a. In France* these are made by applying a solution of Indian rubber in ether, to the silk or foil prepared as above.

b. In England, where ether is expensive, naphtha is employed, or slips of Indian rubber previously boiled in water, or that have had their edges softened with ether, are wound round the wire or foil, and kept in their place by a piece of tape applied over them, as in making elastic tubes. They are afterwards carefully smoothed off.

IV. A common kind of bougie is made by dipping pieces of catgut or soft linen into lead plaster, melted, and rolling it while yet warm upon a slab. *Very inferior.*

V. (*White.*) *Prep.* Yellow wax 1 lb.; spermaceti 1 oz.; finely-powdered sugar of lead ¼ oz.; melt and spread upon slips of old linen, then roll them up while warm with the spread side outwards.

VI. (*Bell's.*) Lead plaster 1 lb.; yellow wax 8 oz.; olive oil 2 oz.; *as last. Very inferior.*

BOUILLI. (French for boiled meat.) This name has been applied by cooks to several dishes of boiled meat, as a refinement on the plain English. Thus "beef bouilli, beef in bouilli, &c.," means, stewed or boiled beef, &c. As, however, the name is à la français, so must be the accompaniments, which generally consist of herbs and vegetable seasoning in greater quantity and variety than is usually deemed essential to a plain-spoken piece of boiled or stewed meat!

BOULES DE NANCY. Equal parts of iron filings and red tartar, made up into balls with spirit. *Use.* As a tonic dissolved in hot water.

BOUQUET DE LA REINE. *Prep.* I. Essence of bergamotte 1 drachm; English oil of lavender 23 drops; oil of cloves and aromatic vinegar, of each 8 drops; essence of musk 10 drops; alcohol ½ oz. Mix.

II. Oils of bergamotte and lavender 30 drops each; neroli 15 drops; oils of verbena and cloves, of each 5 drops. Essences of musk, ambergris, and jasmin, of each ½ drachm; rectified spirit of wine (strongest) 1 oz. Mix.

BOX WOOD MAHOGANY. *Prep.* Warm the wood by the fire, then wash it over with aquafortis, let it stand 24 hours to dry, and polish it with linseed oil reddened with alkanet root, or give it a coat of varnish, made by dissolving aloes and annotto in spirit of wine.

BOYLE'S FUMING LIQUOR. Hydrosulphuret of ammonia is usually employed and sold for this article, but the liquor prepared by Boyle's process contains an excess of sulphur. (Gay Lussac.) The properties of both are however the same.

Prep. Mix 4 parts of fresh slaked lime; 2 of sal ammoniac, and 1 of sulphur, then submit the mixture to distillation.

BRA GRAS. Tar, black rosin, and the dregs of strained rosin, melted together.

BRAIN CAKES. *Prep.* Clean, wash, blanch, and soak the brains, then beat them up with a little white pepper and salt, a sage-leaf or two, scalded and finely chopped, and the yelk of an egg; make them into small cakes or fritters, and fry them.

BRAN. The husk of wheat which immediately covers the grain, and which is left in the bolting machine. *Use.* It is largely employed by the calico printers, when diffused through hot water, to remove the coloring matter from those parts of their goods which are not mordanted. A handful mixed with a pail of warm water, forms an excellent emollient foot-bath. Infused in water, (*bran tea,*) and sweetened, it forms a popular demulcent, much used in coughs and hoarseness, and, taken in quantity, proves gently laxative. It also forms an excellent manure, and, from containing the ammoniaco-magnesian phosphate, is especially adapted for potatoes. It is frequently mixed with flour and made into bread; by the poorer orders.

BRANDY. *Syn.* Eau de Vie. Aqua Vitæ. Spiritus Gallicus. Brandy-wine. The spirituous liquor obtained by the distillation of wine. When first distilled it is colorless, and only acquires a yellowish tint from the wood of the casks, in which state it is known and sold as pale or white brandy. The deep color that it usually possesses, is imparted to it by adding a little spirit coloring, (burnt sugar or caramel,) and occasionally a little red sanders wood as well, and is intended to imitate the appearance acquired by brandy from great age, when kept in wood. The natural color, however, which the spirit receives from the cask, no matter how long it may have been in it, never exceeds an amber tint, about the common color of pale Jamaica rum; but the public taste has been gradually vitiated in this respect, until only a spirit of a lively and full "*brandy color*" (unless for a pale brandy) will sell.

The brandies most esteemed in England are imported from France, and are those of Cognac and Armagnac, the preference being generally given to the former. The brandies of Rochelle and Bordeaux may be reckoned next in quality, while those obtained from Portugal, Spain, and Italy are very inferior.

The constituents of brandy are alcohol and water, and small quantities of volatile oil, acetic acid, acetic ether, œnanthic ether, coloring matter, and tannin. It is from the presence of the last six of these substances that the spirit derives its distinguishing smell and flavor. The quantity of alcohol present in brandy varies from 48 to 55 per cent. When first imported, it is generally 1 or 2 overproof, but by age its strength is lessened, and by the time it is usually taken from the bond store for sale, seldom exceeds 3 or 4 underproof. From considerable personal acquaintance with the cognac trade, I feel confidence in asserting, that brandies of the best quality seldom exceed proof, and are generally below it, and that it is a common practice in France to add spirit of wine and coloring to raise the strength to any given point desired by the English purchaser, and to charge the same in the invoice; or where the purchaser is not *well acquainted with the subject*, and desires a strong spirit at a low rate, to sell him brandy so mixed as genuine. The very finest brandies average from 5 to 10 u. p., and never exceed about 2 u. p.; they then contain more than ½ their weight of water, and from their boiling point being higher, they come over more highly charged with essential oil, and other volatile and fragrant principles of the grape, and thus possess in a greater degree that peculiar aroma and flavor for which they are so much esteemed. French brandy or wine, distilled at a low temperature in a water bath, yields a very pure and scarcely flavored spirit.

The quality of the brandy imported from France varies considerably from that which is drunk on the continent, principally from its being *prepared*, or, as it is technically termed, "*made up,*" for the London market, which means lowering it by the addition of spirit, coloring, &c. above described. The common strength at which foreign brandy is sold in England is about 11 or 12 u. p., and below 17 u. p. it becomes seizable by the excise. The strength at which it is sold and permitted in trade, is generally 10 u. p., to which it is reduced by adding water, and never less than 12 u. p., unless it be specially agreed upon. In large quantities and from bond, of course the strength depends much upon the age and quality of the spirit. A fine old brandy being, perhaps, 8 or 10 *u. p.*, while one of the last year's vintage of a commoner quality may be as strong as 2 or 1 *u. p.* But these distinctions are familiar to every experienced brandy dealer.

In France there are several varieties of this spirit distilled, which are known by names descriptive both of their quality and source. The "*eau de vie supérieure,*" or *cognac brandy*, is generally obtained from pale white wines, by careful distillation, and is remarkable for its superior flavor. When kept in glass or stone bottles, it is called white cognac brandy, and the same term is also generally applied when it has been kept in casks, but has not been artificially colored; in the latter case, however, it generally acquires a pale amber tint.

The "*eau de vie ordinaire,*" or *common brandy*, is distilled from high-colored white or red wines, and has generally a sp. gr. of 0·948, and varies from 22 to 27 u. p.

The "*eau de vie de marc*" is obtained from the lees of vinegar and other wines, the marc or cake of grapes from which the juice has been pressed, and the commonest red wines, fermented and distilled together by a quick fire, to drive over as much essential oil and flavoring as possible.

The "*eau de vie seconde*" is the weak spirit that passes over after the stronger spirit has been drawn off, and the receiver changed. *It is used* for common drinking, or mixed with other brandy.

The "*eau de vie à preuve d'Hollande*" is brandy about 19° Baume, or sp. gr. ·9420, the common strength at which it is retailed in France, and will stand the "*proof*" or "*bead*"

The "*eau de vie à preuve d'huile*" is the strongest brandy usually drunk; it is about 23° Baume, or sp. gr. ·918; pure olive oil will just sink in it; hence the above term.

The "*eau de vie fort*" is usually prepared by the redistillation of common brandy, keeping the first portion separate. It answers to our spirit of wine. It is made of 12 different strengths, distinguished by names, exhibiting the quantity of water required to reduce the sample to the "*preuve d'Hollande.*" The weakest is called cinq-six, or $\frac{5}{6}$, and the strongest trois-neuf, or $\frac{3}{9}$, the difference between the numerator and the denominator being the quantity of water the 3 parts of the former will take to reduce it to the "*preuve*," when it would make 9 parts. Its sp. gr. is about ·839.

The *esprit de vin* is brandy or spirit rectified to 0·890 and upwards.

The general method of distilling brandy in France differs in no important particular from that practised in England, for grain or molasses spirit. Neither are the French workmen more skilful nor more cleanly in their operations than the English. It is the materials alone that, in this case, conduce to the superiority of the product. The quality of the brandy varies with that of the wine from which it has been distilled. Every soil, every climate, every kind of grape, produces a wine possessing some peculiarity confined to itself, and this wine on distillation produces a spirit possessing like distinctions. A large quantity of brandy is prepared in France soon after the vintage, as the juice of the poorer grapes that is unfit for wine is fermented and at once distilled. It is a general rule, in France, to distil only such wines as are unsaleable, as the profits on the wine, sold as such, are much greater than when it is converted into brandy.

The Strength of Brandy may be ascertained in the same way as alcohol, for which purpose Sike's hydrometer is used in England. In France, from the value of spirit being less, it is frequently tested by simpler methods, though great accuracy obtains, in this particular, where necessary.

Pur. Very little perfectly pure French brandy is obtained by the small consumer in England, as it is not only generally lowered a little by the wholesale dealer, but undergoes a like process at the hands of the retailer. The safest method is either to procure it direct from the bond store, without its even entering a private cellar, or to buy of some known respectable party, and to pay a price that will offer no inducement to dishonesty. If this be not done, by all means buy British brandy, which is now made of excellent quality by many of the leading houses, as *Betts*, *Bretts*, *Booth*, and *Grimble*. From the two former a single sealed bottle may be procured at the same price as by the gallon.

The importation of foreign brandy for home consumption amounts to about 1,400,000 gallons a year.

BRANDY, (REDUCED.) I. To 20 gallons of Cognac brandy add 5 gallons of the best British brandy.

II. To 72 gallons of full-flavored French brandy, add 10 gallons of spirit of wine, (58 *o. p.*,) 8 gallons of water, and 1 pint of good coloring. Rummage well up and let it stand until the next day. *Remarks.* The above reduction is generally adopted in trade, and is known by the name of "*improving*." But such is the poverty of the palate of the English brandy drinker, that the adulteration is often not suspected, even when it is carried to double the extent of the above, which is generally exceeded in the hands of the retailer. So long, however, as the foreign spirit constitutes about half of the mixture, and was at first of decent quality and age, the infatuated Englishman smacks his lips, and cunningly holding up his glass between the light and his eye, exclaims, "*Ah! this is a drop of the real.*"

BRANDY, (BRITISH.) *Syn.* British Cognac. Imitation Cognac, &c. From the heavy duty levied on French brandy imported into England for home consumption, it has become a desideratum with the distiller (rectifier) to produce an English spirit of a similar description. For some time the attempt proved quite unsuccessful, but of late years much capital and talent have been embarked in the pursuit, and the result has proved very satisfactory. An article of British manufacture may now be purchased, at a very reasonable rate, of really respectable quality, and possessing much of the flavor and aroma of foreign brandy, while, as a beverage, it is equally wholesome. Much of the British brandy, however, that is commonly met with, is of such a wretched quality as to be quite undeserving of the name, which is evidence of the fact, that much skill and experience is required to ensure success in its manufacture. For a long time this liquor was distilled from spoilt wine and dregs of wine, both British and foreign, mixed with beer bottoms and similar articles; and when, instead of these, corn, malt, and molasses spirit were employed, it was considered as an unpardonable and wicked misuse of those articles. Modern experience has proved, however, that perfectly pure and tasteless malt spirit is the best article to form into an imitation brandy.

The following formulæ, by skilful management, will produce very good brandy, but it must be recollected that much depends on the quality of the materials employed, as well as on the operator. As the strength and quality of the ingredients, and the methods of manipulation vary, so will the result; much must therefore be left to the judgment and discretion of the artist. It offers a profitable pursuit to the ingenious and industrious chemist and rectifier.

Prep. I. Take 12 gallons of the finest flavorless malt spirit at proof, (or if of a different strength a proportionate quantity;) add thereto 5 gallons of water, $\frac{1}{2}$ lb. of the best crude red tartar or winestone, previously dissolved in 1 gallon of boiling water; $\frac{1}{4}$ pint of acetic ether; 2 quarts of good French wine vinegar; 7 lbs. of bruised French plums, and 1 or 2 gallons of wine bottoms or flavor stuff from Cognac, mix them in a fresh-emptied sherry cask, and let them stand together for 14 days, frequently rummaging up the liquor with a stick; next draw over 15 gallons of the mixture from a still furnished with an agitator. Put the rectified spirit into a clean, fresh-emptied Cognac brandy cask, and add thereto $\frac{1}{2}$ pint of tincture of catechu, 1 lb. of fresh and clean oak shavings, and about a pint of good spirit coloring. Bung close, and agitate occasionally for a few days. *Remarks.* Age improves the above article, and renders it

(provided the process be well managed) of a very superior quality. The above receipt yields 15 gallons of brandy 17 *u. p.* The following forms may also be recommended:—

II. Perfectly pure spirit, pf. 99 gallons; red tartar, dissolved, 7 lbs.; acetic ether 3 lbs.; wine vinegar 3 gallons; bruised raisins, or French plums, 7 lbs.; bitter almonds, bruised, 1 oz.; water sufficient. Dissolve the tartar in the water, then add the other ingredients, macerate as before, and draw over 120 gallons; lastly, add a few lbs. of oak shavings, 1 lb. of powdered catechu made into a paste with water and burnt-sugar coloring as before. *Remarks.* This yields 120 gallons of spirit fully 17 *u. p.*

III. Clean spirit 17 *u. p.*, 100 gallons; nitric ether 2 quarts; cassia buds, ground, 4 oz.; bitter almond meal 2 oz.; orris root, sliced, 6 oz.; powdered cloves 1 oz.; capsicum 1½ oz.; good vinegar 2 gallons; brandy coloring 1 quart; powdered catechu 1 lb.; full-flavored Jamaica rum 2 gallons. Mix well in an empty Cognac cask, and let them macerate for a fortnight, occasionally stirring. *Remarks.* The proportion of the ingredients may be varied by the skilful brewer, as much depends on their respective strengths.

IV. Good plain malt spirit, 17 *u.p.*, 100 gallons; finely-powdered catechu 12 oz.; tincture of vanilla 4 oz.; burnt-sugar coloring 1 quart; good rum 3 gallons, or more; acetic or nitric ether 2 quarts. Mix well.

V. Clean spirit, 17 *u.p.*, 89 gallons; high-flavored cognac 10 gallons; oil of cassia 1½ drachms; oil of bitter almonds, essential, ½ a drachm; powdered catechu 10 oz.; cream of tartar, dissolved, 16 oz.; Beaufoy's concentrated acetic acid 3 lbs.; sugar coloring 1 quart, or more; good rum 1 gallon. Put the whole into a fresh emptied brandy piece, and let them remain a week together, with occasional agitation, then let them stand to settle. If this mixture be distilled, the French brandy, rum, coloring, and catechu, should not be added till afterwards.

VI. To colored plain spirit at 17 *u.p.*, add a little tincture of catechu, and a sufficient quantity of essential oil, distilled from wine lees, to give it a proper flavor. This oil is obtained by distillation from the wine lees, either dried and made up into cakes, or in their wet state mixed with about 7 times their weight of water. It should be dissolved in alcohol, and kept in this state, as it is apt to lose its flavor. *Remarks.* When this process is well managed a very capital article results, but it requires considerable address to conduct it well. The spirit produced by this plan is better for distillation. The brandy from any part of the world may thus be imitated, by distilling the oil from the lees of the wines produced in the particular district. This is the only method of producing an exact imitation. A pound each of finely-powdered charcoal and ground rice has been recommended to be digested in a gallon of spirit for a fortnight. Where black tea is cheap, as in America, it is very commonly employed to impart the roughness and flavor of brandy to colored spirits.

BRANDY, CHERRY. *Prep.* I. To every gallon of brandy put an equal measure of cherries, bruised between the fingers; steep for 3 days, then express the liquor; add 2 lbs. of lump sugar, and strain for use.

II. To the above add 1 quart of raspberries, and ½ a pint of orange-flower water. *** Quality very fine.

III. Treacle 1 cwt.; spirit (45 u.p.) 41 gallons; bruised bitter almonds (more or less, to taste) 5 oz.; cloves 1 oz.; cassia 2 oz. Put the ingredients into a large cask, well mix and let them lie a month, occasionally stirring.

Remarks. Equal parts of fully ripe Morello and black cherries produce the richest cordial.

BRANDY, CARAWAY. *Prep.* I. Steep 4 oz. of bruised caraway seeds and 2 lbs. of sugar in 1 gallon of British brandy, for a fortnight.

II. Sugar 1 lb.; caraways 1 oz.; 3 bitter almonds; spirits of wine and water, of each 1 quart; (or spirit 22 u.p. ½ a gallon.) Macerate as above.

BRANDY, DANTZIC. This is distilled from rye, ground with the root of calamus aromaticus. It has a mixed flavor of orrice and cinnamon.

BRANDY, LEMON. *Prep.* I. Steep ¼ lb. of fresh lemon peel and ½ a dozen lemons, cut in slices, in 1 gallon of brandy, for a week, then add 1 lb. of lump sugar.

II. Proof spirit 7 gallons; essence of lemon 3 drachms; sugar 5 lbs.; tartaric acid 1 oz., dissolved in water 2 gallons; coloring q. s. Mix, and rummage repeatedly for 14 days. *Remarks.* Sometimes milk is added to the above, in the proportion of 1 quart (boiling hot) to every gallon.

BRANDY, MALT. Malt spirit, flavored with sweet spirits of nitre and terra Japonica, and colored with treacle, or spirit coloring. (See BRIT BRANDY.)

BRANDY, ORANGE. This may be made in a similar way to lemon brandy.

BRANDY, PEACH. *Prep.* I. From peaches, by fermentation and distillation. Much used in the United States, where peaches are very cheap.

II. Bruise the peaches, then steep them in twice their weight of British brandy, or malt spirit; lastly, express the liquor.

III. Bitter almonds (bruised) 2 oz.; proof spirit (light) 10 gallons; water 3 gallons; sugar 5 or 6 lbs.; orange-flower water ½ a pint. Mix, and macerate for 14 days.

*** Color with brandy coloring, if *required* darker.

BRANDY, RASPBERRY. *Prep.* I. Pour as much brandy over raspberries as will just cover them; let it stand for 24 hours, then drain it off, and replace it with a like quantity of fresh spirit; after 24 hours more, drain this off and replace it with water; lastly, drain well, and press the raspberries quite dry. Next add sugar to the mixed liquors, in the proportion of 2 lbs. to every gallon, along with a ¼ of a pint of orange-flower water.

II. Mix equal parts of mashed raspberries and brandy together, let them stand for 24 hours, then press out the liquor. Sweeten as above, and add a little cinnamon and cloves, if agreeable; lastly, strain.

BRASS. An alloy of copper and zinc.

Hist. and Prep. Brass was formerly manufactured by cementing granulated copper, or copper clippings, with calcined calamine and charcoal, in crucibles, exposed to a bright heat. The alloy

was found in lumps at the bottom of the crucible on cooling. These were remelted and cast into ingots. At the present day, brass is generally made by direct union of the metals. This process requires much care, owing to the different degrees of fusibility of copper and zinc. The proper quantity of zinc is first melted, and slips of copper plunged into it, which are rapidly dissolved, as it were, and the addition is continued until an alloy is formed, somewhat difficult of fusion, when the remainder of the copper is added. The brass thus formed is broken into pieces, and remelted under charcoal, and a proper addition of either zinc or copper made, to bring it up to the color and quality desired. It is next cast into plates, or other forms, in moulds of granite. When submitted to the rolling-press for reduction to *thin* plates, it requires to undergo the operation of annealing several times.

Prep. I. (*Fine Brass.*) 2 parts of copper to 1 part of zinc. *Remarks.* This is nearly 1 equivalent each of copper and zinc, if the equivalent of the former metal be taken at 63·2; or 2 equivalents of copper to 1 equivalent of zinc, if it be taken, with Liebig and Berzelius, at 31·6.

II. Copper 4 parts, zinc 1 part. An excellent and very useful brass.

III. (*Gold-colored Brass.*) *Syn.* RED BRASS. DUTCH GOLD. TOMBAC. SIMILOR. PRINCE'S METAL. PINCHBECK, &c.

a. Copper and zinc, equal parts.

b. Copper 2 parts; zinc 1 or 1½ parts. This is Manheim gold.

c. Copper 3 to 5½ parts; zinc 1 part. Deep colored.

Remarks. The proportion of zinc in this alloy is altered to suit the color and other properties to the purposes for which it is intended, and often varies from ⅓ to ½, or ⅙ of the weight of the alloy. At the celebrated works of Hegermühl, near Potsdam, the proportions are 11 parts of copper to *two* of zinc, which produces a metal which is afterwards rolled into sheets for the purpose of making Dutch leaf-gold.

BRASS, BUTTON. (*Best.*) I. Copper 8 parts; zinc 5 parts, as above.

II. (*Common.*) Copper 50 parts; zinc 40 parts; tin 4 parts; lead 6 parts.

BRASS, FOR SOLDER. *Syn.* HARD SOLDER. I. 12 parts of brass; 6 parts of zinc, and 1 of tin, melted together.

II. 2 parts of brass, and 1 of zinc.

III. (*Very strong.*) 3 parts of brass, and 1 of zinc.

BRASS, TURNER'S. 98 parts of brass, and 2 of lead. *Remarks.* The addition of lead improves the brass for the uses of the turner, but lessens its malleability.

BRASS, CLEANING OF. Brass and copper are best cleaned with sweet oil and tripoli, powdered bath-brick, rotten-stone, or red brick-dust, rubbed on with flannel and polished with leather. A strong solution of oxalic acid in water gives brass a fine color. Vitriol and spirits of salts make brass and copper very bright, but they very soon tarnish, and consequently require more frequent cleaning. A strong lye of roche-alum and water will also improve brass.

Brass inlaid work may be cleaned as follows:—Mix tripoli and linseed oil, and dip into it a rubber of hat, with which polish the work. If the wood be ebony or rosewood, polish it with a little finely-powdered elder-ashes; or make a paste of rotten-stone, a little starch, sweet-oil, and oxalic acid, mixed with water. The ornaments of a French clock are, however, best cleaned with bread-crumb, carefully rubbed, so as not to spoil the woodwork. Ormolu candlesticks, lamps, and branches, may be cleaned with soap and water. They will bear more cleaning than lacquered articles, which are spoiled by frequent rubbing, or by acids, or strong alkalis.

BRASS COATING. I. Brass plates and rods may be covered with a superficial coating of brass, by exposing them in a heated state to the fumes of melted zinc, at a high temperature. *Use.* For rolling into thin plates, or drawing into wire. The celebrated spurious gold wire of Lyons is thus made.

II. Vessels of copper may be coated with brass, internally, by filling them with water strongly acidulated with muriatic acid, adding some amalgam of zinc and cream of tartar, and then boiling for a short time.

BRASS-COLORED PIGMENT. *Syn.* BRASS BRONZE. *Prep.* I. (*Red.*) Grind copper filings, or precipitated powder of copper, with a little red ochre.

II. (*Yellow or gold-colored.*) Gold-colored brass, or Dutch leaf reduced to a very fine powder.

Remarks. Both these powders are mixed up with varnish, and used as a paint. No more should be mixed at a time than wanted for immediate use. They are also used by dusting them over any surface, previously covered with varnish to make them adhere. (See OXIDE OF COPPER.)

BRASS-COLORED VARNISH. *Prep.* Dissolve 1 oz. each of pale shell lac and gum sandarach, in ½ a pint of rectified spirit of wine.

Use. To mix up the preceding powders.

BRASS, PASTE FOR CLEANING. *Prep.* I. Soft soap 2 oz., rotten-stone 4 oz.; beat them to a paste.

II. Rotten-stone made into a paste with sweet oil.

III. Rotten-stone 4 oz.; oxalic acid 1 oz.; sweet oil 1½ oz.; turpentine enough to make a paste.

Use. To clean brass. The first and last are best applied with a little water. The second, with a little spirits of turpentine, or sweet oil. Both require friction with soft leather.

BRASS ORNAMENTS, PRESERVATION OF. Brass ornaments, when not gilt or lacquered, may be cleansed, and a fine color given to them by two simple processes. The first is to beat sal ammoniac into a fine powder, then to moisten it with soft water, rubbing it on the ornaments, which must be afterwards rubbed dry with bran and whiting. The second is to wash the brass-work with roche alum boiled to a strong lye, in the proportion of an ounce to a pint; when dry, it must be rubbed with fine tripoli. Either of these processes will give to brass the brilliancy of gold.

BRASS STAIN. I. Cut sheet-brass into small pieces, and expose it to a strong heat for 2 or 3 days, then powder it, and again expose it for several days to a like heat; again powder and sift,

and expose it a third time to heat, testing it occasionally, to see if it be properly burnt. When this is the case, a little of it fused with glass will make the latter swell and froth up.

Uses, &c It imparts to glass a green tint, passing into torquoise.

II. Calcine equal parts of plate-brass and sulphur, stratified together in a crucible, until they become friable; then powder and expose them again, as last.

Use. Imparts a calcedony red or yellow tinge to glass by fusion, according to the mode of using it.

BRAWN, CHOICE. When young, the horny parts feel moderately tender; if the rind be hard, it is old.

BRAWN, MOCK. *Prep.* Take the head and belly piece of a young porker, well saltpetred; split the head and boil it; take out the bones and cut it to pieces; then take four ox-feet boiled tender, and cut them in thin pieces; lay them in the belly piece, with the head cut small; roll it up tight with sheet tin, and boil it four or five hours. When it comes out, set it up on one end, put a trencher on it within the tin, press it down with a large weight, and let it stand all night. The next morning take it out of the tin, and bind it with a fillet, put it into cold salt and water, and it will be fit for use; it will keep a long time, if fresh salt and water are put into it every four days.

BRAZIL WOOD. *Syn.* Sapan Wood. Saint Martha Wood. Fernambuca. This wood is much used in dyeing. A decoction is made by boiling for some hours in hard spring water, and this is generally kept for some time, or until it undergoes a species of fermentation, as it is thus found to yield more permanent and beautiful colors than when employed quite new. *Use.* To dye *red.*

BRAZIL WOOD DYE. I. (*For cotton and linen.*) *a.* First boil the goods in a bath of sumach, next work them through a weak mordant of solution of tin, and then run them through the Brazil bath, lukewarm. This gives a bright red.

b. First alum the goods and rinse them, then give them a mordant of solution of tin, rinse again, and turn them through the dye-bath. This gives a rose color.

Remarks. The shades of this dye may be varied by the strength of the bath, mordant, &c. A little alum added to the Brazil-bath, gives a purple tint. 1 lb. of Brazil wood, ½ oz. of alum, and 2 oz. of tartar will dye 20 to 25 lbs. of cotton.

II. (*For silk.*) The silk, after being well alumed in the same way as wool, but at a lower temperature, is rinsed, and passed through the decoction of Brazil, just lukewarm.

Remarks. By adding a little alkali to the bath, or by passing the silk through a water holding a little alkali in solution, after it is dyed, will produce what is called the false crimson. When wanted of a very deep crimson, a little logwood is added to the Brazil-bath. In this way any shade of color may be produced.

III. (*For wool.*) Boil the wool in water holding in solution 5 parts of alum and 1 of tartar, for 1 hour; then let it lie in the cold liquor for several days, frequently moving it about; lastly, boil it in a decoction of Brazil for ½ an hour.

BRAZILINE. *Syn.* Breziline. The coloring principle of Brazil wood, obtained by Chevreul in small orange-colored needles. It is soluble in both water and alcohol; alkalis turn it violet, acids yellow. With alum it dyes red.

BRAZING. The operation of uniting the edges of pieces of copper, brass, iron, &c., by means of hard solder.

Proc. The edges, after being filed quite clean, are covered with a mixture of hard solder and powdered borax, made into a paste with water. The whole is then allowed to dry, and afterwards exposed in a clear fire to a heat sufficient to melt the solder.

Remarks. In some cases a little silver is added to the solder, when it receives the name of "*silver solder.*"

BREAD. *Principles of bread-making, &c.* This most important article of food is made of the flour of different grains, but only those that contain gluten admit of conversion into light spongy bread. Hence it is that wheat flour is best calculated for this purpose. When flour is made into a stiff paste or dough with water, and rolled into cakes and baked, it forms biscuits, or unleavened bread, which was once the only description known. When the dough, previously to baking, is left for some time in a moderately warm place, varying from 80° to 120°, a state of fermentation comes on, formerly called the panary fermentation, but which is, in reality, the sugar of the flour gradually undergoing the process of conversion into alcohol, and resembles in every respect the same change which takes place in the manufacture of wine, beer, &c. During this process, a large quantity of carbonic acid gas is liberated, and the toughness of the dough preventing its escape, the whole mass becomes puffed up and spongy, and a light porous paste is formed, ready for baking into bread. The natural process of fermenting the dough just described, is, however, subject to much uncertainty, and is inconvenient from the time it occupies to complete it, and the tendency the dough has to run into the acetous fermentation, when it acquires a sour and disagreeable taste, and is rendered less nutritious and easy of digestion. This has led to the use of a *ferment*, which at once excites a proper state of fermentation throughout the mass, and speedily renders it light and spongy. *Leaven* or *dough*, already in a state of fermentation, was originally employed for this purpose, and the bread so made was hence called *leavened bread.* But this has been wholly superseded by barm or yeast. Thus it will be seen that all that is essential to make a loaf of bread, is to add a proper quantity of yeast to the dough, and to allow it to remain for a short time in a warm place, until it rises or becomes spongy, when it must be subjected to the operation of baking. If the process be well managed, and the flour be good, bread of superior quality will be produced.

Process of making bread. In preparing his dough, the modern baker takes a part of the water needed for the batch, and having warmed it to a temperature of about 80° or 90°, dissolves his salt therein, and then adds the yeast and a portion of the flour. These he works up into a dough, which he sets aside in a warm place usually provided for

the purpose, and called the "*kneading trough*," where it soon begins to ferment and swell up. This process is called "*setting the sponge*," and according to the proportion the water in it bears to the whole quantity that is to be used, it receives the name of "*whole*," "*half*," or "*quarter sponge*." The evolution of carbonic acid in the process of fermentation, causes the sponge to heave and swell, and when the surface bursts, it subsides, and then swells again and again in a similar manner. This action would go on for some time, if not interfered with; but the baker is careful to stop it before it has communicated a sourness to the mass. After the *first*, or at the *furthest*, after the second or *third* "*dropping of the sponge*," he adds the remaining quantity of flour, water, and salt, necessary to form the batch. These he incorporates by long and laborious kneadings, until the entire mass acquires uniformity, and is sufficiently tough and elastic to bear the pressure of the hand without adhering to it. The dough is now left to itself for a few hours, during which time fermentation goes on, after which the inflated mass is again kneaded, when it is ready to be cut into pieces and weighed. These pieces are then shaped into loaves, and set aside for an hour or two, during which time they swell up to nearly double their former size; they are then placed in the oven and baked. During this operation they continue for a time to increase in size, in consequence of the dilation of the pent-up gas by the heat of the oven, until at length the fermentation is checked, and the dough becomes too solid to admit of further alteration.

Remarks. A number of other processes are used by cooks and confectioners to make the different varieties of fancy bread, cakes, puddings, &c., most of which vary according to the peculiar characteristic it is desired to communicate to them. Thus some kinds of cakes and pastes are made to eat "*short*," as it is called, or are rendered less tenacious, and a species of brittleness imparted to them by the addition of starch and sugar. In pastry a similar effect and peculiar lightness is produced by butter or lard, while in some articles, white of egg, gum-water, isinglass, and other adhesive substances are added to produce an exceedingly light and porous mass.

The different varieties of bread made in England vary chiefly in their quality, according to the flour of which they are formed. *The best white bread* is made from the purest wheat flour; *ordinary wheaten bread*, of flour to which a little of the finest bran has been added; *seconds*, from flour containing a still larger portion of bran; and common household bread, from flour produced by grinding the whole substance of the grain without any separation of the bran. Symnel bread, manchet or roll bread, and French bread are varieties made of the purest flour, from the finest wheat, a little milk being usually added for rolls, and butter and eggs for choicer purposes. Several other minor kinds of bread are also made, varied by the addition of sundry trifles, as sugar, currants, and other palatable ingredients. The Scotch "short bread" is made from a *very thick dough*, to which butter, sugar, orange-peel, and spices, are added. (See Gingerbread.)

In France a number of different kinds of bread are made. The "*pain bis*" is the coarsest sort, and is made of a mixture of groats and wheat flour; the "*pain bis blanc*" is made of a mixture of oatmeal and wheat flour; the "*pain blanc*" of flour from which the finest portion has been sifted; the "*pain mollet*," or soft bread, is made of the purest wheat flour, from the finest grain; the "*pain chaland*," made from the same materials as the last, but the paste is pounded; the "*pain chapalé*" is a small variety of bread, similar to the French or roll bread of England; the "*pain cornu*" is a kind of small bread, named from being done up into four-cornered pieces; the "*pain de la reine*" is another variety of small bread, and the "*pain gruau*" is a bread which has been made of late years in Paris, prepared from the small granular particles separated from the best wheat after a slight grinding. The French have also their soup bread and their country white bread, besides several other varieties, not mentioned in the above list.

In the manufacture of white bread from damaged or inferior flour, a large quantity of alum is employed by the bakers, but with the best flour no alum is required. The utmost beauty, sponginess, and sweetness, may be given to bread without the addition of one particle of alum, provided the best materials are employed. As such is not, however, generally the case, it is a common practice with the bakers to introduce 4 or 5 oz. of alum to every sack of flour, or about 1 oz. to each bushel. The method of detecting this adulteration will be presently explained. The proper quantity of salt to be used is 6 or 7 lbs. to the sack, or 1¼ lbs. to the bushel. 1 sack of the best flour, and 6 lbs. of salt, ought to yield about 360 lbs. of *good bread*, and a sack of seconds 345 to 350 lbs. of bread.

Wheaten bread, made of pure materials, is one of the most wholesome articles of food, and has been justly termed the staff of life. When well fermented and baked, it is very easy of digestion. It should never be eaten till it has stood 24 hours after being taken out of the oven, as newer bread is apt to disagree with the stomach, frequently producing flatulence, heartburn, and indigestion.

Adult. This is often carried to a fearful extent: Mr. Accum says, "The bakers' flour is very often made of the worst kinds of damaged foreign wheat, and other cereal grains mixed with them in grinding the wheat into flour. In this capital, no fewer than six distinct kinds of wheaten flour are brought into the market. They are called fine flour, seconds, middlings, fine middlings, coarse middlings, and twenty-penny flour. Common garden beans and peas are also frequently ground up among the London bread flour.

"The smallest quantity of alum that can be employed with effect to produce a white, light, and porous bread, from an inferior kind of flour, I have my own baker's authority to state, is from 3 to 4 oz. to a sack of flour weighing 240 lbs."

"The following account of making a sack of five bushels of flour into bread, is taken from Dr. P. Markham's 'Considerations on the Ingredients used in the Adulteration of Flour and Bread,' (p. 21:) 5 bushels of flour; 8 oz. of alum; 4 lbs. of salt; ½ gallon of yeast, mixed with about 3 gallons of water.

"Another substance employed by fraudulent

It is, perhaps, more *frequently* used, and in a *greater variety* of complaints, than any other medicine.

CALUMBINE. *Syn.* CALOMBINE. The bitter principle of calumba root. It is extracted by alcohol or ether from the root, reduced to a coarse powder, and is purified by repeated resolutions and evaporations. When pure, it forms prismatic crystals, or delicate white needles; it readily combines with acetic acid, and the compound is intensely bitter; hence vinegar, or sour wine, would be the best menstruum to make infusion of calumba with. The properties of calumbine are similar to those of calumba root.

CALVES' FEET JELLY. *Prep.* For each foot take 3 pints of water, and boil it to one-half; then let it cool, and skim off the fat. It must now be boiled for 2 or 3 minutes, with the peel of a lemon, and a little spice, when it should be removed from the fire, strained through a flannel bag, and the juice of a lemon and a glass of wine added; when cooled a little, it may be put into glasses or forms.

Remarks. If wanted very transparent, the jelly, after the fat is removed, should be gently warmed, just enough to melt it, and then well beaten with the white of an egg and the seasoning, after which it must be brought to a boil for a minute or two, when it will be ready for straining, and being mixed with the wine. The addition of a little beet-root juice will give it a beautiful color. The calf's feet should not be bought ready boiled, but only scalded. Cows' feet or heels make as good jelly as that from calves' feet, and are much more economical.

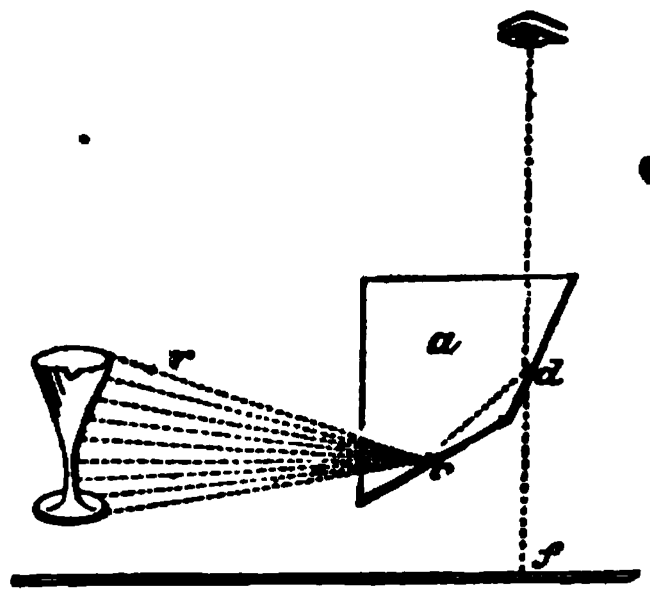
CALX OF ANTIMONY. *Syn.* DIAPHORETIC ANTIMONY. Impure antimonious acid, prepared by deflagrating crude antimony with 3 times its weight of saltpetre.

CAMELEON, MINERAL. *Prep.* Heat to redness a mixture of equal parts of black oxide of manganese, and nitre or potassa.

Prop., &c. When dissolved in water, its solution, at first green, passes spontaneously through all the colored rays to the red, when, if potassa be added, the color retrogrades until it reaches the original green. The addition of oil of vitriol, or chlorine, renders the solution colorless. The addition of a weak acid, or even boiling or agitating the liquid, will turn it from green to red.

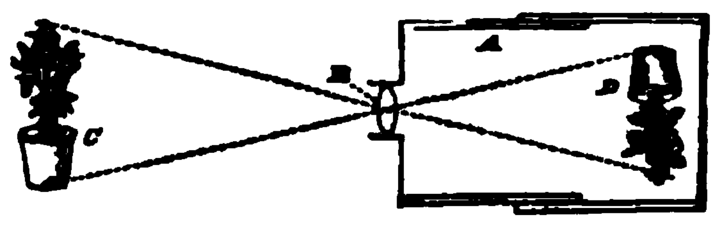
CAMERA LUCIDA. An instrument invented by Dr. Wollaston, for the purpose of enabling persons ignorant of drawing or perspective, to trace the outlines of distant objects or landscapes with accuracy.

Prin. and Cons. When a ray of light (*r*) falls upon a quadrangular glass prism, (*a*,) it is bent by two reflections, (at *c* and *d*,) and thrown upwards where it may be received by the eye, to which it will appear described on the table or sheet of paper, (*f*,) placed to receive it. The point of a pencil used to trace any object on the paper, can also be seen, and by its means the picture may therefore be easily copied. Various modifications of this instrument exist. When the prism is mounted on a stand, and a thin brass plate, with a small hole through it for the eyepiece, adjusted thereto, it forms the instrument sold by the opticians. The image may be magnified or lessened by placing a lens, so as either to intercept the rays before they strike the prism, or before they reach the eye. An ingenious person will readily be able to set up the instrument.



CAMERA OBSCURA Literally, a dark chamber. An optical apparatus, by which the images of external objects are thrown upon any white surface, placed in an obscure situation to receive them, whereby they are represented in their natural forms and colors.

Prin. and Cons. A convex lens (*B*) is placed in a hole admitting the light into a darkened box or chamber, (*A*,) which, falling on a white ground (*D*) within the room, produces an inverted picture of every object within its range. The image thus formed may be restored to its natural position, by allowing the rays of light to pass through two lenses instead of one, or by receiving the rays on a mirror placed at an angle of 45°, when the image will be thrown on the floor in its original position. The picture may be viewed through an oblong aperture cut in the box, or the experiment may be performed in a darkened room, by placing the lens in a hole in the shutter, allowing the image to fall on the wall, (white,) or a sheet of paper stretched to receive it. The following engraving will explain the construction of this instrument.



A, A box formed of two parts, to slide one within the other, to adjust the screen or hind wall to receive the image.
B, Convex lens.
C, External object.
D, Ditto painted in a reversed position on a screen or wall.

When intended as an instrument for taking views or portraits, the image is thrown upon a mirror placed at an angle of 45°, and resting on the bottom of the box, by which means it is thrown upwards against a plate of glass, also placed at a similar angle. On this is laid a piece of semi-transparent paper, when the object is seen painted on it, and may be traced out with a pencil.

CAMPHOR. *Syn.* CAMPHIRE. KAMPHUR. CAMPHORA, (*Lat.*) *Hist. and Source.* The camphor of commerce is a natural production. It is principally extracted from the laurus camphora, or laurel camphor tree, but it is also found in several other members of the vegetable kingdom

It is occasionally found in small masses, between the bark and the wood, in a perfectly pure state. The Chinese and Japanese extract the camphor by cutting the wood into small pieces, and boiling it with water in iron vessels,—which are covered with large earthen capitals or domes,—lined with rice straw. As the water boils, the camphor is volatilized along with the steam, and condenses on the [illegible]w, under the form of grayish granulations. In this state it is collected and transported to Europe, when it undergoes the process of refining into white camphor.

Proc. of Refining. 100 parts of crude camphor are mixed with 2 parts each of quicklime and animal charcoal, and placed in a thin globular glass vessel, sunk in a sand-bath. The heat is then cautiously applied, and the vessel gradually and carefully raised out of the sand as the sublimation goes on. When this is completed, the whole is allowed to cool.

Remarks. If the process be conducted too slowly, or at a heat under 375° Fahr., the product will be flaky, and consequently unsaleable, without remelting or subliming. An improvement on this process would be, simply to sublime the above mixture in any convenient vessel, furnished with a large and well-cooled receiver, and to remelt the product in close vessels under pressure, when it hould be cooled as rapidly as possible.

Prop., Uses, &c. A white semi-crystalline solid, very volatile at common temperatures. Soluble in alcohol, ether, oils, and acetic acid, and sufficiently so in water (about 1¼ grs. to 1 oz.) to impart its characteristic smell and taste. It is stimulant, narcotic, anodyne, and diaphoretic, and is given in doses of 2 to 20 grs., in the form of pills or bolus, or made into an emulsion with yelk of egg, mucilage, or almonds. An overdose of camphor is accompanied with symptoms of poisoning. The best antidote is opium. Camphor is frequently put into wardrobes and clothes-trunks, to keep away insects, and it is used to make the white stars and fire of the pyrotechnist. Mixed with copal, it renders that gum soluble in some essential oils and alcohol. (See COPAL.) Mixed with six times its weight of clay, and distilled, it undergoes decomposition, and yields a yellow aromatic oil, smelling strongly of thyme and rosemary, which, I am told, is much used to adulterate some of the more costly essential oils.

CAMPHOR, ARTIFICIAL. Kind first discovered, and Trommsdorff and Boullay confirmed the fact, that rectified oil of turpentine, exposed to the action of muriatic acid, absorbs that gas with the production of a white crystalline mass resembling camphor.

CAMPHOR FROM ESSENTIAL OILS. *Prep. &c.* By careful distillation of ½ of the oil, the remaining portion, on being cooled, will be found to contain a species of camphor, on separating which, and redistilling the remainder of the oil, 2 or 3 times, the whole of the camphor may be obtained. *Oil of rosemary*, treated in this way, yields about 10% of camphor; *oil of sweet marjoram* the same; *oil of sage* yields 13%; *oil of lavender* 25%. That from sage oil forms cubical crystals, insoluble in nitric acid; that from marjoram oil is scarcely volatile or inflammable. By keeping the oils loosely corked, and in a cool place, they produce a larger portion of this pseudo-camphor. The substance called *aniseed camphor* is procured by pouring off the liquid portion of the oil, after it has been partially frozen by exposure to a cool atmosphere.

CAMPHOR CAKE. *Prep.* I. Camphor liniment, (P. L.,) 1 oz.; melted spermaceti 1 drachm; mix.

II. White almond oil 4 oz; spermaceti ¾ oz.; melt, add camphor, (cut small,) 1 oz.; stir until melted, then pour it into shapes and allow it to crystallize.

CAMPHOR JULEP, CONCENTRATED *Syn.* ESSENCE OF CAMPHOR. *Prep.* Camphor 1 oz.; rectified spirit 10 oz. by weight; dissolve. *Use.* 20 drops, added to 1 fluid oz. of pure cold water, makes transparent camphor julep.

CAMPHOR, TO POWDER. Camphor may be beaten in a mortar for some time, without being reduced to powder, but if it be first broken with the pestle, and then sprinkled with a few drops of spirit of wine, it may be readily pulverized. Powdered camphor is much used in tooth powders, fireworks, &c.

CAMPHORATED ACETIC ACID. *Prep.* Dissolve ℥ss of camphor, in ℥viss of acetic acid, (P. E.) *Use.* Similar to aromatic vinegar.

CAMPHORATED CHALK. *Syn.* CRETACEOUS TOOTH POWDER. *Prep.* I. Precipitated chalk 3 oz.; camphor 1 oz. *Proc.* Add a few drops of spirit of wine to the camphor, then reduce it to a fine powder, and mix it (perfectly) with the chalk; lastly, pass it through a clean sieve of sufficient fineness.

II. Prepared chalk (not precipitated) 7 oz.; camphor 1 oz.; as last.

Use. Extensively employed as a dentifrice. It should be kept in corked bottles, to prevent the camphor flying off.

CAMPHORIC ACID. *Prep.* Put 1 part of camphor and 4 parts of nitric acid, sp. gr. 1·33, into a glass retort, connected with a receiver, and apply a gradually increasing heat, until vapors cease to be extricated; then add the camphor that has been volatilized to the acid in the retort, along with 4 or 5 parts more of nitric acid. Repeat the process again and again, until 20 parts of nitric acid have been consumed. When the whole of the camphor is acidified, it will crystallize in the remaining liquor. When the whole is perfectly cold, it must be thrown upon a filter and well washed with distilled water, after which it must be dissolved in boiling water, evaporated to a pellicle, and set aside to crystallize.

Prop. The crystals somewhat resemble those of muriate of ammonia. They are soluble in alcohol, and are not precipitated from it by water, by which camphoric acid may be distinguished from benzoic acid. With the bases it forms salts called camphorates. The soluble camphorates may be made by digesting the carbonate or hydrate of the base in a hot solution of the acid, and the insoluble ones, by double decomposition.

CAMPHORIC ETHER. *Syn.* CAMPHORATE OF OXIDE OF ETHULE. *Prep.* By heating camphoric acid, sulphuric acid, and alcohol together, a colorless, sirupy liquid is formed, which must be submitted to distillation, and the product dissolved in alcohol. When the liquid ceases to deposite crystals of camphoric acid, water must be added, when

the attention of organic chemists, from being a modification of the principle called proteine by Mulder. When caseine is thrown down from milk by adding an acid, it combines with a little of it, forming a kind of salt. With sulphuric acid a sulphate of caseine is formed. The acid may be removed by means of carbonate of lead, when pure caseine is left behind. LEGUMINE is vegetable caseine. By first adding a little caustic potassa to albumen, and then some alcohol, a precipitate is formed, having all the properties of caseine. (Liebig.)

CASKS, PRESERVATION OF. Casks last longest when kept either in a dry situation, or one uniformly very moist. The continual variation from the one to the other speedily rots them. As soon as casks are emptied they should be bunged down quite air-tight, with as much care as if they were full, by which means they will be preserved sweet. Should any of the hoops become loose, they should be immediately driven up tight, which will at once prevent the liability of their being lost or misplaced, as well as the casks fouling or becoming musty from the admission of air. Good casks are very expensive articles. The casks and vats belonging to the great brewery of Barclay & Co., of London, are said to be worth several score thousand pounds.

CASKS, SWEETENING MATCH FOR. *Prep.* Dip a strip of coarse linen cloth into melted brimstone. *Use.* Set fire to the brimstone match formed as above, put it into the cask, and keep it suspended by fastening one end under the bung, which should be driven in tight. After the lapse of 1 or 2 hours, the match may be removed.

CASKS, STINKING OR MUSTY, (TO (SWEETEN.) For this purpose numerous plans are followed, among which the following may be mentioned. In every case great care should be taken to scald or well wash the casks out before filling them with liquor.

I. Wash them well out with oil of vitriol, diluted with an equal weight of water; afterwards soak them in clean water and rinse them well.

II. Wash them first with a little chloride of lime and hot water, then with water soured with oil of vitriol, and lastly, with pure water, until all the fumes and smell are removed.

III. Match them with sulphu or with sulphur mixed with a very little saltpetre

IV. Unhead them and whitewash them with milk of lime, made pretty strong. This plan is commonly followed for brewer's vats.

V. Remove the heads and char the insides of the staves, by the aid of a fire of shavings, kindled within them. A safer and more effectual method is to wash the *dry* casks out with the most concentrated oil of vitriol. This will char not only the surface of the staves, but penetrate into *all* the cracks, which the fire cannot reach. The expense is trifling. The strongest oil of vitriol, sp. gr. 1·845, may be bought in quantity at 1½*d.* per lb., and 1 gallon, worth about 2*s.*, will wash out upwards of 50 hogsheads, if common care be taken not to waste it. *Caution.* As oil of vitriol is powerfully caustic and corrosive, great care should be taken to avoid splashing it over the skin or clothes, as it will rapidly burn them.

VI. Steam has lately been applied to the insides of casks, with great advantage. High-pressure steam is driven in at the bung-hole, at the same time that the cask is violently agitated, (a heavy chain having been previously put into it,) until all the dirt and bad smell is removed. This plan has been lately patented.

VII. Washing the casks out with a lye of pearl-ash, or soda, with milk of lime, strong hot brine, cow-dung, salt and water, and other similar liquors has been adopted, by some persons. The coopers boil the staves for gin casks in a strong lye of alum before placing them together, to prevent their coloring the spirit, but washing with oil of vitriol is a better plan. Some persons fill musty casks with water, and add 3 or 4 lbs. of coarsely-powdered charcoal, and agitate well for a few days.

CAST ENGRAVINGS. These are made by taking a mould from any kind of engraving, and in pouring on this mould an alloy, in a melted state, capable of taking the finest impression. Bronze, type metal, zinc, &c., have been used for this purpose.

This plan is particularly applicable to engravings which meet with a ready sale, and of which a large number is required. As soon as one cast is worn out, another may be taken from the original plate, so that not only will every impression be a proof, but the whole expense of retouching will be avoided. For another method of multiplying engravings, see ELECTROTYPE.

CASTS, (IN FUSIBLE METAL.) A combination of 3 parts of lead, with 2 of tin, and 5 of bismuth, forms an alloy which melts at the temperature of 197° Fahr.

In taking casts with this and similar alloys, it is important to use the metal at a temperature as low as possible; as, if but a few degrees elevated, the water which adheres to the things from which casts are to be taken is converted into vapor, and produces bubbles. The fused metal must be allowed to cool in a teacup until just ready to set at the edges, and then poured into the moulds. In this way beautiful casts from moulds of wood, or of other similar substances, may be procured. When taking impressions from gems, seals, &c., the fused alloy should be placed on paper or pasteboard, and stirred about till it becomes pasty, from cooling, at which moment the gem, die, or seal, should be suddenly stamped on it, and a very sharp impression will then be obtained. (Jour. of Science, No. 26.)

CASTORINE. *Syn.* CASTORINA. CASTOREUM CAMPHOR. *Prep.* Cut castor into small pieces and boil it in 6 times its weight of alcohol. On cooling, it will deposite the castorine, which, by re-solution in alcohol, may be obtained under the form of prismatic acicular crystals.

Remarks. Genuine Russian castor must be employed in the above process, as scarcely any castorine can be obtained from the American. Castorine is soluble both in ether and hot alcohol, is inflammable, and by long boiling with nitric acid, becomes converted into castoric acid. This acid is capable of forming salts with the bases.

CATALEPSY. *Syn.* CATALEPSIS. CATALEPSIA. TRANCE. A disease in which the organs of sense and motion cease to exercise their functions, and the heart and lungs feebly perform their offices and in a scarcely perceptible manner. The

paroxysm generally comes on without previous warning, and its duration varies from a few minutes to several days, and if medical reports are to be credited, sometimes for a much longer period. Dr. Cullen affirms that this disease is always counterfeited, but this surely cannot be correct.

Treat. Ammoniacal stimulants applied to the nostrils, and spirituous liquors injected into the stomach, with general friction and free access to pure air, are the best remedies. Electricity and galvanism should also be had recourse to, when the instruments are at hand.

CATARRH. *Syn.* CATARRHUS. In popular language, a cold in the head or chest. Influenza is a severer form of this complaint, and has been called epidemic catarrh.

The common symptoms of catarrh are a copious discharge from the eyes and nose, a hoarseness, and generally a cough, more or less severe. The exciting causes are sudden changes of temperature and exposure to currents of cold air, while the body is heated; hence the frequency of colds in changeable weather.

Treat. A light or spoon diet should be adopted, and animal food and fermented or spirituous liquors should be particularly avoided. The bowels should be opened with some mild aperients, and if the symptoms be severe, or fever or headache be present, small diaphoretic doses of antimonials, accompanied by copious draughts of diluents, as barley-water, weak tea, or gruel, should be taken. Unless in very bad cases, this treatment, with proper care, will generally effect a cure.

CATECHINE. *Syn.* CATECHUIC ACID. RESINOUS TANNIN. *Prep.* Cubical gambir or catechu, powdered and treated with cold water, leaves an insoluble residuum, which, by repeated solutions in alcohol, may be obtained under the form of white silky needles.

Prop. It strikes a green color with the salts of iron, but does not precipitate gelatine. When dissolved in caustic potassa, and the solution exposed to the air, oxygen is absorbed and JAPONIC ACID formed. If, instead of caustic potassa, the carbonate be employed, it is converted into RUBINIC ACID.

CATGUT. *Syn.* CORDE A BOYAU, (*Fr.*) DARMSAITE, (*Ger.*) The prepared and twisted intestines of animals. *Prep.* The guts, taken while warm from the animal, are thoroughly cleaned, freed from adherent fat, and well rinsed in pure water. They are next soaked for about 2 days in water, after which they are laid on a table and scraped with a copper-plate, having a semi-circular notch, beginning the operation at the smaller end. The guts are then put into fresh water, and soaked until the next day, when they are again scraped, the larger ends cut off, and after well washing, again steeped for a night in fresh water, and then for 2 or 3 hours in lye water, each gallon of which contains 1 oz. each of pearlash and potash. They are lastly washed in clean water, and passed through a polished hole in a piece of brass to smooth and equalize their surface, and then twisted and sorted according to the purposes for which they are intended.

Remarks. Catgut is employed in several of the arts. The strings of harps, and all the instruments of the violin class, are formed of this material. For this purpose the mucous and peritoneal membranes are removed with great care, they are then soaked for a day or two in water, to which potash is added, then removed to water impregnated with burnt lees of wine, which is made stronger by degrees, scraping them carefully to separate the fat. As soon as the intestines begin to float, they are immediately taken out, twisted, brimstoned, again twisted, and dried; when sufficiently dry, the catgut is rubbed over with olive oil, and kept as long as convenient before use, as it improves by age. *Whipcord* is made from catgut, which is sewed together while soft with the *filandre* or scrapings, after which it is put into a frame and twisted. It next receives 1 or 2 sulphurings, and is then dyed and coiled up for sale. Red and black ink, infusion of logwood, to which a little alum or blue vitriol has been added, (blue and purple,) distilled verdigris or sap green, are the dyes commonly employed. *Bowstrings* for hatmakers are made out of the largest intestines, 4 to 12 of which are twisted together, until the cord is extended to 15 to 25 feet in length. It is then rubbed perfectly smooth and free from knots, half dried, sulphured twice, again stretched and sulphured, and lastly, dried in a state of tension. *Clockmaker's cords* are made of the smallest intestines. When wanted particularly small, they are slit into strings by means of a knife, fitted with a ball to guide it. In this operation the gut is strained over the ball, and an equal portion of the divided gut pulled down by each hand, while the knife remains immoveable. This method is similar in principle to that by which the barrels of straws are divided by the straw-plait makers.

The best *fine* catgut comes from Italy, and is made at Venice or Rome. The superiority arises from its being prepared from the intestines of thin sinewy sheep, while that made in England is formed from the fat sheep killed for the shambles. It has long been known to physiologists, that the membranes of healthy lean animals are much tougher than those of fat ones. This is well exemplified in the human species; few men being at the same time very muscular and corpulent.

A coarse species of catgut, used for turning lathes and similar purposes, is made from the intestines of horses. The guts, previously cleaned, are soaked in water, with a pailful of weak solution of chloride of lime for each 8 or 10 sets; the mucous membrane is then separated, the intestine cut into 4 strips by forcing a ball with 4 knives placed crosswise along them; these strips are next twisted, and when dry, any slight inequalities removed by fish skin.

CATHARTICS. *Syn.* PURGATIVES. These have been divided into 5 orders or classes, according to their particular actions. The following are the principal of each class.

1. (*Laxatives, lenitives, or mild cathartics.*) Manna, cassia pulp, tamarinds, prunes, honey, and phosphate of soda; castor, almond, and olive oils; ripe fruit.

2. (*Saline, or cooling laxatives.*) Epsom salts, glauber salts, phosphate of soda, (tasteless salts,) seidlitz powders, &c.

3. (*Active cathartics, occasionally acrid, frequently tonic and stomachic.*) Rhubarb, senna, aloes, &c.

4. (*Drastic or violent purgatives.*) Jalap,

scammony, gamboge, croton oil, colocynth, elaterium, &c.

5. (*Mercurial purgatives.*) Calomel, blue-pill, quicksilver with chalk, &c.

The doses of all the above will be found in the table of the doses of medicines, as well as at the end of the notices of most of them, in their alphabetical order.

CATHARTINE. The purgative principle of senna, obtained by Lassaigne and Fenuelle from a strong aqueous infusion of the leaves. *Prep.* Evaporate to the consistence of a sirup, out of contact with the air, then digest in alcohol, filter, and evaporate. *Prop.* Color, reddish; taste and smell, nauseous; it is soluble in water and alcohol, and strongly cathartic.

CATHETER. A long hollow tube introduced into the bladder, for the purpose of drawing off its contents. Catheters are either made of metal or elastic gum; and if of the former material, a suitable shape is given to them, for the purpose of accommodating them to the flexure of the urethra.

Prep. I. Coat a piece of smooth catgut with melted wax, and while still warm, bend it to a proper shape. When cold, dip it repeatedly into an ethereal solution of Indian rubber, until a sufficient thickness is obtained, dry by a gentle heat, and then boil it in water to melt out the wax, and to allow the catgut to be withdrawn. A piece of polished steel wire may be used instead of catgut.

II. Instead of applying the caoutchouc in solution, wind ribands of it round the wire, having previously softened their edges with ether, or by boiling in water. Over this wind, as tightly as possible, a strong silk riband, and over all some fine packthread. The next day boil the whole in water for half an hour, and withdraw the wire; lastly, polish off the outside as smoothly as possible. (See CAOUTCHOUC.)

III. Weave a smooth tissue of silk over the bent wire, and then coat it with a surface of Indian rubber, or elastic varnish. Finish it off as before.

CAUDLE, (IN COOKERY.) A species of gruel. Made with oatmeal, groats, rice, or wheat flour, and mixed with half its weight of good ale, and as much mace, nutmeg, sugar, &c., as will make it agreeable. White wine, the juice of a lemon, a little of the peel grated, with 1 or more eggs, are frequently added. It is an excellent domestic remedy for colds, &c., unaccompanied with fever, for which purpose it should be taken on going to rest.

CAUSTICS. Substances that corrode or destroy the texture of the skin and organized bodies. Their action is commonly called "burning."

The principal caustics employed by surgeons are, *nitrate of silver*, *caustic potassa*, *sulphate of copper*, *red oxide of mercury*, and the *nitric* and *acetic acids*.

Use. Caustics are employed to remove excrescences, morbid growths, granulations, &c., as corns, warts, and proudflesh, and to open issues, abscesses, &c.

CAUSTIC, COMMON. *Syn.* POTASH WITH LIME. POTENTIAL CAUTERY. POTASSA CUM CALCE. *Prep.* Hydrate of potassa and quicklime, equal parts; rub them together in a mortar, and keep them in a well-corked bottle. (P. L.) *Use.* When placed on the skin, it rapidly decomposes it, leaving a soft eschar, which is slowly detached. It is employed to open issues, abscesses, &c.

CAUSTIC, COMMON. *Syn.* CAUSTICUM COMMUNE MITIUS. (P. L. 1745.) *Prep.* Soft soap and quicklime, equal parts. Mix them at the time of use.

Remarks. Both the above are less liable to spread than pure potassa, but are considerably weaker.

CAUSTIC, (FOR CANKER IN HORSES.) *Prep.* Dissolve corrosive sublimate ½ oz. in muriatic acid 1 oz., then add rectified spirit and water, of each 4 oz.

CAUSTIC, OPIATE. *Syn.* COMMON CAUSTIC WITH OPIUM. Common caustic 4 dr.; powdered opium 1 dr.; soft soap enough to mix. *Use.* Applied to fungous ulcers.

CEMENT. Any substance which, on being placed between two surfaces, makes them adhere together. This name is also applied (in architecture) to some species of mortars, employed either to unite stones or bricks into masses, or as a protective covering against the weather or water.

CEMENT, ALABASTER. *Prep.* I. Finely-powdered plaster of Paris, made into a cream with water.

II. Melt yellow resin, or equal parts of yellow resin and beeswax, then stir in half as much finely-powdered plaster of Paris.

Use. The first is used to join and fit together pieces of alabaster or marble, or to mend broken plaster figures. The second is used to join alabaster, marble, porphyry, Derbyshire spar, and any similar substances, that will bear being heated. It must be applied hot, and the stone must be made warm. Derbyshire, and some other stones, may also be joined by heating them sufficiently to melt a lump of sulphur, with which their edges must be then smeared, after which they must be placed together, and held so until cold. Little deficiencies, as chips out of the corners, &c., may be filled up with melted sulphur or bleached shellac, colored to any shade, as required.

CEMENT, ARCHITECTURAL. *Prep.* I. Reduce paper to a smooth paste by boiling it in water; then add an equal weight each of sifted whiting and good size; boil to a proper consistence.

II. Paper, paste, and size, equal parts; finely-powdered plaster of Paris, to make it of a proper consistence. Use it as soon as mixed.

Use. To make architectural ornaments, busts, statues, columns, &c. It is very light, and receives a good polish, but will not stand the weather.

CEMENT, ARMENIAN. *Syn.* DIAMOND CEMENT. PERSIAN DITTO, TURKISH DITTO. This article, so much esteemed for uniting pieces of broken glass, for repairing precious stones, and for cementing them to watch cases and other ornaments, is made by soaking isinglass in water until it becomes quite soft, and then mixing it with spirit in which a little gum mastic and ammoniacum have been dissolved.

The jewellers of Turkey, who are mostly Armenians, have a singular method of ornamenting watch-cases, &c., with diamonds and other precious stones, by simply glueing or cementing them on. The stone is set in silver or gold, and the lower part of the metal made flat, or to correspond with the part to which it is to be fixed; it is then warmed gently, and has the glue applied, which

is so very strong that the parts thus cemented never separate; this glue, which will strongly unite bits of glass, and even polished steel, and may be applied to a variety of useful purposes, is thus made in Turkey:—Dissolve five or six bits of gum mastich, each the size of a large pea, in as much spirits of wine as will suffice to render it liquid; and in another vessel, dissolve as much isinglass, previously a little softened in water, (though none of the water must be used,) in French brandy or good rum, as will make a two-ounce vial of very strong glue, adding two small bits of gum galbanum, or ammoniacum, which must be rubbed or ground till they are dissolved. Then mix the whole with a sufficient heat. Keep the glue in a vial closely stopped, and when it is to be used, set the vial in boiling water. Some persons have sold a composition under the name of Armenian cement, in England; but this composition is badly made; it is much too thin, and the quantity of mastich is much too small. (Eton.)

II. The following are good proportions: isinglass, soaked in water and dissolved in spirit, 2 oz., (thick;) dissolve in this 10 grains of very pale gum ammoniac, (in tears,) by rubbing them together; then add 6 large tears of gum mastich, dissolved in the least possible quantity of rectified spirit.

III. Isinglass, dissolved in proof spirit, as above, 3 oz.; bottoms of mastich varnish (thick but clear) 1½ oz.; mix well.

Remarks. When carefully made, this cement resists moisture, and dries colorless. As usually met with, it is not only of very bad quality, but sold at exorbitant prices.

CEMENT, BRUYERE'S WATER. *Prep.* Mix 3 gallons of clay with 1 gallon of slaked lime, and expose them to a full red heat for 3 hours.

CEMENT, BUILDING. *Syn.* ARTIFICIAL PUZZOLENE. *Prep.* This is made by exposing a mixture of clay or loam, broken pottery, flints, or silicious sand, or broken bottle-glass, with wood ashes, to a considerable heat in a furnace, until it becomes partially vitrified. It must then be ground to a fine powder, sifted, and mixed with one-third its weight of quicklime, also in fine powder, after which it must be packed (tight) in casks to preserve it from the air and moisture. For use, it is mixed up with water, and applied like Roman cement.

CEMENT, BOTANY BAY. Yellow gum and brickdust equal parts, melted together. Used to cement coarse earthenware, &c.

CEMENT, CHINESE. *Prep.* Dissolve shellac in enough rectified spirit to make a liquid of the consistence of treacle.

II. Instead of spirit, use wood naphtha, (pyroxilic spirit.)

III. Boil borax 1 oz. and shellac 4 oz in water until dissolved.

Use. To mend glass, china, fancy ornaments, &c. The first form produces a cement so strong that pieces of wood may be joined together, cut slopingly across the grain, and will afterwards resist every attempt to break them at the same place. In many of the islands of the Indian Ocean, in Japan, China, and the East Indies, a similar cement is used to join pieces of wood for bows, lances, &c. The fluid is thinly smeared over each face of the joint, a piece of very thin gauze interposed, and the whole pressed tightly together and maintained so until the next day Joints so made will even bear the continual flexure of a bow without separating.

CEMENT, COPPERSMITHS'. Bullock's blood thickened with finely powdered quicklime. *Use.* To secure the edges and rivets of copper boilers, to mend leaks from joints, &c. It must be used as soon as mixed, as it rapidly gets hard. It is extremely cheap and very durable, and is suited for many purposes where a strong cement is required. It is frequently called *blood cement.*

CEMENT, CUTLERS'. *Prep.* I. Black rosin 4 lbs.; beeswax 1 lb.; melt, then add 1 lb. of finely-powdered and well-dried brickdust.

II. Equal weights of rosin and brickdust melted together.

Use. To fix knives and forks in their handles.

CEMENT, EGG. White of egg thickened with finely-powdered quicklime. *Use.* To mend earthenware, glass, china, marble, alabaster, spar ornaments, &c. It does not resist moisture.

CEMENT, ELECTRICAL AND CHEMICAL, (SINGER'S.) I. Rosin 5 lbs.; wax and dry red ochre, in fine powder, of each, 1 lb.; plaster of Paris 4 oz.; melt the first two, then add the ochre, and, lastly, the plaster. Mix well together.

II. Black rosin 7 lbs.; well-dried red ochre and plaster of Paris, of each, 1 lb.; as above.

Use. To cement the plates in voltaic troughs, join chemical vessels, &c.

CEMENT, ENGINEERS'. I. Mix ground white-lead with as much powdered red-lead as will make it of the consistence of putty.

II. Mix equal weights of red and white lead with boiled linseed oil to a proper consistence.

Use. Employed by engineers and others to make metallic joints. A washer of hemp, yarn, or canvass smeared with the cement is placed in the joint, which is then "brought home," or screwed up tight. It dries as hard as stone.

This cement answers well for joining broken stones, however large. Cisterns built of square stones, put together, while dry, with this cement, will never leak or come to repair. It is only necessary to use it for an inch or two next the water; the rest of the joint may be filled with good mortar. It is better, however, to use it for the whole joint.

CEMENT, EXTEMPORANEOUS. Shellac melted and run into small sticks the size of a quill. *Use.* To join glass, earthenware, &c. The edges must be heated sufficiently hot to melt the cement, which must be then thinly smeared over them, and the joint made while they are still hot. This is the cement so commonly vended in the streets of London.

CEMENT, FRENCH. *Prep.* Make a thick mucilage with gum arabic and water, then add starch in fine powder to thicken it. *Use.* Employed by naturalists and French artificial-flower makers. A little lemon juice is sometimes added.

CEMENT FOR IRON BOILERS, &c. *Prep.* Dried clay in powder 6 lbs.; iron filings 1 lb.; make a paste with boiled linseed oil Used to stop the cracks and leaks in iron boilers, stoves, &c.

CEMENT FOR BROKEN GLASS, CHINA, &c Various preparations and methods are adopted for mending broken china, earthenware, and glass, among which are the following: the white of an egg beaten with quicklime, in impalpable powder, into a paste; to which is sometimes added a little whey, made by mixing vinegar and milk. A little isinglass, dissolved in mastich varnish, is another cement. Nature supplies some cements ready to our hands, as the juice of garlic and the white slime of large snails; and it has been stated in a respectable scientific journal that a broken flint has been joined so effectually with this snail cement, that when dashed upon a stone pavement the flint broke elsewhere than at the cemented part. In their anxiety to unite broken articles, persons generally defeat themselves by spreading the cement too thickly upon the edges of the article, whereas the least possible quantity should be used, so as to bring the edges almost close together; and this may be aided by heating the fragments to be joined. (Chambers's Information for the People.)

(See also ARMENIAN, EXTEMPORANEOUS, CHINESE CEMENTS, &c. &c.)

CEMENT, GAD'S HYDRAULIC. *Prep.* Mix 3 lbs. of well-dried and powdered clay with 1 lb. of oxide of iron; then add as much boiled oil as will reduce them to a stiff paste.

Use. For work required to harden under water.

CEMENT, GLASS GRINDERS'. I. Melt pitch and add thereto one fourth of its weight each of finely-powdered wood-ashes and hard tallow. For coarse work.

II. Melt 4 lbs. of black rosin, then add 1 lb. each of beeswax and whiting previously heated red hot and still warm.

III. Shellac melted, and applied to the pieces previously warmed.

Use. To fix the articles while grinding.

CEMENT, GLUE. *Prep.* I. Melt 1 lb. of glue without water, then add 1 lb. of black rosin and 4 oz. of red ochre.

II. Melt glue without water, then stir in ¼ of its weight each of boiled oil and red ochre.

Use. For various common purposes, especially to fix stones in their frames.

CEMENT, HAMELIN'S, (OR MASTICH.) To any given weight of the earth or earths, commonly called pit-sand, river-sand, rock-sand, or any other sand of the same or the like nature, or pulverized earthenware or porcelain, add two thirds of such given weight of the earth or earths, commonly called Portland stone, Bath stone, or any other stone of the same or like nature, pulverized. To every 560 lbs. of these earths, so prepared, add 40 lbs. of litharge, and with the last-mentioned given weights combine 2 lbs. of pulverized glass or flint stone. Then join to this mixture 1 lb. of minium and 2 lbs. of gray oxide of lead.

When this composition is intended to be made into cement, to every 605 lbs. of the composition are added 5 gallons of vegetable oil, as linseed oil, walnut oil, or pink oil. The composition is then mixed in a similar way to mortar.

When this cement is applied to the purpose of covering buildings intended to resemble stone, the surface of the building is washed with oil.

CEMENT, IRON. This is formed of the borings or turnings of cast-iron, which should be clean and free from rust, mixed with a small quantity of sal ammoniac and flowers of sulphur. When wanted for use, it is mixed up with just enough water to thoroughly moisten it, and it is rammed or calked into the joints with a blunt calking chisel and hammer, after which the joint is screwed up by its bolts as tightly as possible. If the turnings or borings be very coarse, they are broken by pounding in an iron mortar, and the dust sifted off before use. The following are good proportions.

I. Sal ammoniac in powder 2 oz.; flowers of sulphur 1 oz.; iron borings 5 lbs.; water to mix.

II. Sal ammoniac 1 oz.; sulphur ½ oz.; iron borings 6 lbs.; water to mix.

III. Sal ammoniac 2 oz.; iron borings 7 or 8 lbs.; water to mix.

IV. Iron borings 4 lbs.; good pipeclay 2 lbs.; powdered potsherds 1 lb.; make them into a paste with salt and water.

Remarks. The first of these forms is that generally employed for common purposes, but formerly much more sulphur and sal ammoniac were used. I am informed by one of the leading engineers of London, that the strongest cement is made without sulphur, and with only 1 or 2 parts of sal ammoniac to 100 of iron borings, (see the third form;) but that when the work is required to dry rapidly, as for steam joints of machinery wanted in haste, the quantity of sal ammoniac is increased a little, and occasionally a very small quantity of sulphur is added. This addition makes it set quicker, but reduces its strength. As the power of the cement depends on the oxidizement and consequent expansion of the mass, it is evident that the less foreign matter introduced the better. No more of this cement should be made at a time than can be used at once, because it soon spoils. I have seen it become quite hot by standing even a few hours, when it contained sulphur; and I have been informed by workmen, that when much sulphur is used, and it has been left together in quantity all night, combustion has taken place.

The last form produces a cement that gets very hard when allowed to dry slowly.

CEMENT, JAPANESE. *Syn.* RICE GLUE. *Prep.* Intimately mix the best powdered rice with a little cold water, then *gradually* add boiling water, until a proper consistence is acquired, being particularly careful to keep it well stirred all the time; lastly, it must be boiled for 1 minute in a clean saucepan or earthen pipkin.

Use. This glue is beautifully white, and almost transparent, for which reason it is well adapted for fancy paper work, which requires a strong and colorless cement.

CEMENT, KEENE'S MARBLE. The following is an abstract of a paper read by Mr. White before the Society of Arts, and will explain the preparation of this beautiful and useful cement: "Keene's Marble Cement is described as a combination of sulphate of lime and alum.* The gypsum undergoes the same preparation as for plaster of Paris, being deprived of its water of crys-

* A pleasing tint is given to this cement by adding a little solution of green copperas to the alum liquor.

tallization by baking. It is then steeped in a saturated solution of alum; and this compound, when recalcined and reduced to a powder, is in a fit state for use. This cement has been most extensively applied as a stucco; but the finer qualities, (when colored by the simple process of infusing mineral colors in the water with which the cement powder is finally mixed for working,) being susceptible of a high degree of polish, produce beautiful imitations of mosaic, and other inlaid marbles, scagliola, &c. The cement is not adapted to hydraulic purposes, or for exposure to the weather, but has been used as a stucco in the internal decorations of Windsor and Buckingham palaces. From its extreme hardness, it has been found serviceable when used for imbedding and setting the tiles of tesselated pavements, &c.; and has been adopted for this purpose at the French Protestant church, the new fire-proof chambers in Shorter's Court, and the Reform Club-House."

In the course of the discussion which followed, Mr. C. H. Smith and Mr. Lee adverted to the extreme hardness of the cement as its principal recommendation, when applied as stucco and for mouldings.

CEMENT, MAHOGANY. *Prep.* I. Melt beeswax 4 oz.; then add Indian red 1 oz., and enough yellow ochre to produce the required tint.

II. Shellac, melted and colored as above. Very hard.

Use. To fill up holes and cracks in mahogany.

CEMENT, OPTICIAN'S. *Prep.* I. Shellac, softened with rectified spirit or wood naphtha. For fine work.

II. Melt wax 1 oz., and resin 15 oz.; then add whiting 4 oz.; previously made red hot, and still warm.

III. Resin 1 lb.; melt, then add plaster of Paris (dry) 4 oz.

Use. To fix glasses, stones, &c., while polishing and cutting. The last is a very strong cement for rough purposes.

CEMENT, PARABOLIC. *Syn.* Universal Cement. *Prep.* Curdle skim-milk, press out the whey, and dry the curd by a *gentle heat*, but as quickly as possible. When it has become quite dry, grind it to powder in a coffee or pepper mill, and mix it with $\frac{1}{10}$ of its weight of finely-powdered quicklime, and a piece of camphor the size of a pea, also reduced to powder, to every ounce of the mixture. Keep it in wide-mouth 1 oz. vials, well corked. *For use*, make it into a paste with a little water, and apply it immediately.

CEMENT, PARKER'S. This valuable cement is made of the nodules of indurated and slightly ferruginous marl, called by mineralogists septaria, and also of some other species of argillaceous limestone. These are burned in conical kilns, with pit coal, in a similar way to other limestone, care being taken to avoid the use of too much heat, as if the pieces undergo the slightest degree of fusion, even on the surface, they will be unfit to form the cement. After being properly roasted, the calx is reduced to a very fine powder by grinding, and immediately packed in barrels, to keep it from the air and moisture.

Use. It is tempered with water to a proper consistence, and applied at once, as it soon hardens, and will not bear being again softened down with water. For foundations and cornices exposed to the weather, it is usually mixed with an equal quantity of clean angular sand; for use as a common mortar, with about twice as much sand; for coating walls exposed to cold and wet, the common proportions are 3 of sand to 2 of cement, and for walls exposed to extreme dryness or heat, about 2½ or 3 of sand to 1 of cement; for facing cistern work, water frontages, &c., nothing but cement and water should be employed.

This cement, under the name of compo, or Roman cement, is much employed for facing houses, water-cisterns, setting the foundations of large edifices, &c.

CEMENT, PLUMBER'S. *Prep.* Melt black rosin 1 lb., then stir in brickdust 1 to 2 lb. Sometimes a little tallow is added.

CEMENT, ROMAN. Genuine Roman cement consists of *puzzolene*, (a ferruginous clay from Puteoli, calcined by the fires of Vesuvius,) lime, and sand, mixed up with soft water. The only preparation which the puzzolene undergoes is that of pounding and sifting; but the ingredients are occasionally mixed up with bullock's blood and oil, to give the composition more tenacity.

CEMENT, SEAL ENGRAVER'S. Common resin and brickdust melted together.

Use. To fix the pieces of metal while cutting, and also to secure seals and tools in their handles. It grows harder and improves every time it is melted.

CEMENT, TURNER'S. Pitch, rosin, and brickdust melted together.

CEMENT, WATER. *Prep.* I. Good gray clay 4 parts; black oxide of manganese 6 parts; good limestone, reduced to powder by sprinkling it with water, 90 parts; mix, calcine, and powder.

II. Mix white iron ore (manganese iron ore) 15 parts, with lime 85 parts; calcine and powder as above. Both this and the preceding must be mixed up with a little sand for use. A piece thrown into water will rapidly harden.

III. Fine clean sand 1 cwt.; quicklime in powder 28 lbs.; bone ashes 14 lbs. For use, beat it up with water as quickly as possible.

CEMENT, WATERPROOF, (OF DIHL.) Pure clay, dried by a gentle heat, and powdered, mixed up to the consistency of a paste with boiled linseed oil.

Remarks. It may be colored by adding a little red or yellow ochre, or any similar pigment. It is used to cover the fronts of buildings, roofs of verandas, &c. It may be thinned with turpentine.

CEMENTATION, (in Metallurgy.) The operation of surrounding a solid body with powder or some other body, and in this state exposing it to the action of heat. Steel and porcelain undergo cementation.

CERATES. Unctuous preparations possessing a consistence intermediate between ointments and plasters. The term is derived from Cera, wax, because that is the ingredient on which their solidity mainly depends.

In the preparation of cerates, the oils and fats used should be perfectly fresh, and the wax unadulterated. It is a general custom with the druggists to use a less quantity of wax than what is required to give the compound a proper consistence, and in many cases it is omitted altogether, and its

place supplied by hard suet or stearine, and frequently rosin. Lard is also very generally substituted for olive oil. The operation of melting the ingredients should be performed in a water or steam bath, and the liquid mass should be assiduously stirred until cold.

CERATE, BLISTERING. *Syn.* CERATE OF SPANISH FLIES. CERATUM CANTHARIDES. (P. L.) *Prep.* Spanish flies in fine powder ℥j; spermaceti cerate ℥vj; soften the cerate by heat, then carefully mix in the powdered flies.

Use. To keep blisters open, and as a mild stimulant. Its use is sometimes, however, attended by strangury and other disagreeable symptoms. A blister on the scalp, dressed for 4 days with this cerate, was followed by the head swelling to an alarming size, an œdematose erysipelas over the face and scalp to the occlusion of the eyes, and great fever. These symptoms were removed by the use of emollient fermentations and simple dressings. (A. T. Thompson.) Very probably the cerate contained euphorbium, which it derived from the powdered flies being adulterated with this substance. (See CANTHARIDES.)

CERATE, CALAMINE. *Syn.* CERATUM EPULOTICUM, (P. L. 1745.) CERATUM LAPIS CALAMINARIS, (P. L. 1788.) CERATUM CALAMINÆ, (P. L. 1836.) HEALING SALVE. TURNER'S CERATE. *Prep.* Prepared calamine (lapis calaminaris) and wax, of each lb. ss; olive oil f℥xvj. *Proc.* Mix the oil with the melted wax, and as soon as it begins to thicken, add the calamine and stir until cold.

Use. To dress excoriations, ulcers, burns, sore nipples, &c. It is drying and healing.

Remarks. On the large scale this cerate is usually made without a particle of wax. 4 lbs. of suet are melted with 3 lbs. of lard, and 3½ lbs. of calamine sifted in; the whole is then well mixed up for a few minutes, and after one minute's repose, it is poured off into another vessel, a little coarse sediment that has fallen to the bottom being left behind. It is then stirred until cold. In many cases nothing but lard and calamine are used.

CERATE, CALAMINE, (WITH MERCURY.) *Prep.* (CERATUM CALAMINÆ CUM HYDRARGYRO, P. C.) Calamine cerate lb. j; nitric oxide of mercury ℥j. *Proc.* Triturate the oxide until reduced to an impalpable powder, then add the cerate and thoroughly blend them together.

CERATE, CALOMEL. *Prep.* Simple cerate ʒvij; calomel ʒj; mix.

CERATE, CALOMEL, (COMPOUND.) Calamine cerate ℥ij; calomel ℥j; mix.

CERATE, CINCHONA. (Paris Codex.) Equal parts of extract of cinchona and simple cerate, mixed together.

CERATE, COMPOUND LEAD. *Syn.* GOULARD'S CERATE. CERATUM PLUMBI COMPOSITUM, (P. L.) *Prep.* Solution of diacetate of lead f℥iij; wax ℥iv; olive oil ½ pint; camphor ʒss. *Proc.* Add 8 oz. of the oil to the melted wax, and as soon as it begins to cool, add the solution of lead, and continue the stirring until cold; then add the camphor dissolved in the remaining portion of the oil.

Use. A cooling cerate for burns, excoriations, &c.

CERATE COMPOUND MERCURIAL. *Syn.* CERATUM HYDRARGYRI COMPOSITUM, (P. L.) *Prep.* Mercurial ointment and soap cerate, of each ℥iv; powdered camphor ℥j; mix.

Use. As a stimulant application to indolent tumors, and as a resolvent in enlarged joints, &c.

CERATE, COPPER. *Syn.* CERATUM CUPRI. *Prep.* Liquor of ammoniated copper 1 part; simple cerate 8 parts. *Proc.* Soften the cerate by heat, then add the cupreous solution, and stir until cold. (Swediaur.)

CERATE, COSMETIC. *Syn.* POMMADE EN CREME. *Prep.* Oil of almonds 5 oz.; white wax and spermaceti, of each ½ oz.; melt, add rose water 3 oz., and tincture of balsam of Mecca ¼ oz.; stir until cold.

CERATE, HEMLOCK. (CERATUM CONII, St. B. H.) Hemlock ointment 12 oz.; spermaceti 2 oz.; white wax 3 oz.; melt the last two, then add them to the first, softened by a gentle heat. Used for inveterate cancerous, scrofulous, and other sores.

CERATE, HONEY (CERATUM MELLIS, P. C.) Lead plaster and beeswax, of each 4 oz.; olive oil 6 oz.; melt and add honey 6 oz.

CERATE, KIRKLAND'S NEUTRAL. *Prep.* Lead plaster ℥viij; olive oil and prepared chalk, of each ℥iv; mix with heat and add sugar of lead ʒiij, dissolved in distilled vinegar f℥iv. Stir until cold. *Use.* As a cooling dressing for indolent ulcers.

CERATE, MARSHALL'S. *Prep.* Palm oil and calomel, of each 2 oz.; sugar of lead 1 oz.; ointment of nitrate of mercury 4 oz.; mix thoroughly by rubbing them together in a Wedgewood mortar.

CERATE, MERCURIAL. (CERATUM MERCURIALE, P. L. 1746.) Strong mercurial ointment and yellow wax, of each 6 oz.; lard 3 oz. Melt the wax and lard together, then stir in the ointment.

CERATE OF ACETATE OF LEAD. (CERATUM PLUMBI ACETATIS, P. L.) Acetate of lead in fine powder ʒij; wax ℥ij; olive oil f℥viij; melt the wax in 7 oz. of the oil; then add the acetate of lead, separately rubbed down with the remaining oil; stir until cold.

Use. As a cooling cerate to burns, excoriations and inflamed sores.

CERATE OF ARSENIC. (CERATUM ARSENICI, P. U. S.) White arsenic in fine powder ℈j; simple cerate ℥j; mix.

CERATE OF NITRATE OF MERCURY. (CERATUM HYDRARGYRI NITRATIS, St. B. H.) *Prep.* Ointment of nitrate of mercury and simple cerate, equal parts; mix.

CERATE, OPIUM. (CERATUM OPII, DR. LAGNEAU.) *Prep.* Opium in fine powder ʒss; yelk of 1 egg; mix, then rub it up with simple cerate ℥ij.

CERATE, QUININE. (CERATUM QUINIÆ, F. H.) Sulphate of quinine 1 part; simple cerate 10 parts; mix well.

CERATE, RESIN. *Syn.* YELLOW BASILICON. BASILICON CERATE. CERATUM CITRINUM, (P. L. 1745.) C. RESINÆ FLAVÆ, (P. L. 1788.) CERATUM RESINÆ, (P. L. 1809, 1824, and 1836.) *Prep.* Yellow resin and wax, of each lb. j; melt; then add olive oil f℥xvj. Stir until cold.

Remarks. This cerate is a mild stimulant, de-

tergent, and digestive application; and is employed to dress foul and indolent ulcers.

The above is the form of the Lond. Ph., but the basilicon of the shops is seldom, if ever, made in this manner. The following forms are those commonly used on the large scale, but the product is inferior to the P. L.

II. Yellow resin 10 lbs.; beeswax 2 lbs.; linseed oil 7 lbs.; melt together and stir until cold.

III. As last, but use nut oil for linseed oil.

IV. Nut oil 1 gall.; beeswax 5 lbs.; yellow resin 14 lbs.

V. Lard (common) and linseed oil, of each 3 lbs.; yellow resin 9 lbs.; mix as before.

CERATE, ROSE. *Syn.* LIP SALVE. (CERATUM ROSATUM, P. Cod.) Oil of almonds 1 lb.; white wax ½ lb.; alkanet root 1 oz.; melt and digest until sufficiently colored, strain, and when cooled a little, add otto of roses (24 drops) to perfume.

CERATE, SAVINE. (CERATUM SABINÆ, P. L.) *Prep.* Lard lbs. ij; savine leaves lb. j; wax ℥viij. *Proc.* Melt the wax and lard, and boil the leaves in the mixture, then strain through a linen cloth.

Remarks. The preparation of this cerate requires caution, as the active principle of the savine being volatile, is injured by long boiling or too high a temperature. The leaves are usually boiled until they are crisp, but as this takes some time, the essential oil, and consequently the odor, is nearly all dissipated. A better plan is to express the juice from the leaves, and to add it to the wax and oil melted together, and just beginning to cool. As usually met with, this ointment has a deep green color, and the odor of the fresh plant, but neither of these is derived from the leaves, in the common process of making it. The first is caused by the addition of verdigris, and the latter by adding a little of the essential oil of savine to the compound when nearly cold. The cerate prepared according to the form of either of the British Colleges, has but a very pale green color, and that rapidly changes unless it be well covered up from the air. A greater quantity of color is got from the leaves by long digestion in the fat and wax in earthen vessels, at a moderate heat, than by hastily boiling. In this way a lively green is sometimes produced, but it rapidly changes.

The following forms are those that have been adopted by many druggists for the manufacture of this cerate.

II. Lard and suet, of each 6 lbs.; yellow wax 2 lbs.; melt them together in an earthen vessel; then add 2 oz. of distilled verdigris, previously rubbed down smooth in a mortar, with an equal weight of sweet oil; strain while hot into a large earthen pot, and when cooled a little, add 1 oz. of oil of savine; stir till cold.

III. Savine leaves 4 lbs.; yellow wax 2 lbs.; lard 8 lbs.; boil until the leaves become crisp; then strain, and add, of lively-colored green ointment 5 lbs.; and when cooled a little, 3 drs. of oil of savine. Stir briskly until cold. *Prod.* 13½ lbs.

The practice of coloring this cerate with verdigris, which is next to universal, cannot be too severely censured, as its therapeutic action is thereby altered. The copper may be detected by burning down a little in a platinum or Hessian crucible, washing out the ashes with a little dilute acid, placing the liquor in a glass tube, and pouring thereon liquid ammonia. When a blue color, ammoniureted copper will be produced, if copper be present.

Use. To keep blisters open.

CERATE, SOAP. (CERATUM SAPONIS, P. L.) *Prep.* Boil litharge ℥xv in distilled vinegar 1 gallon until dissolved, stirring continually; then add of Castile soap ℥x; boil again until the moisture be entirely evaporated: then add gradually, wax ℥xiiss, and olive oil 1 pint, previously melted together.

Remarks. Unless the above instructions be exactly followed in every particular, the process will miscarry. When this is the case, it will be found that the cerate on cooling will separate into two portions, and be full of hard gritty particles. To prevent this, care should be taken to use soap of the best quality. When once this mishap occurs, no boiling or stirring in the world will remove it. The only remedy is the addition of a little more soap, previously melted with some water, and again evaporating to a proper consistence. A small quantity of liquor of potassa will also have the same effect.

The color and consistence of this cerate wholly depend upon the length of time it is kept heated after the addition of the oil and wax. As evaporation proceeds, so do the color and consistence increase. Its usual color is that of a lively pale chocolate-brown, but occasionally it is much paler. This arises from its containing moisture, which, by stirring, reduces the color. The following form may be used on the large scale.

II. Distilled vinegar 6 galls.; litharge 5 lbs.; soap 3¼ lbs.; yellow wax 4½ lbs.; olive oil 6 pints. Mix as above. (Good nut or poppy oil may be used for olive oil.)

Uses. Soap cerate is used as a cool dressing for scrofulous swellings, &c. It may be spread on linen and applied like a plaster.

CERATE, SIMPLE. *Syn.* OIL AND BEESWAX. SIMPLE DRESSING. CÉRAT SIMPLE, (*Fr.*) CERATUM SIMPLEX, (P. L. 1824.) CERATUM, (P. L. 1809 and 1836.) *Prep.* Olive oil f℥iv; yellow wax ℥iv; mix by heat, and stir until cold.

Remarks. This is the ceratum of the "London Pharmacopœia." It is used as a simple emollient dressing for excoriations and sores. The ceratum simplex of the Scotch College is spermaceti cerate. Simple cerate is but little used, preference being given to the next preparation.

CERATE, SPERMACETI. *Syn.* WHITE LIP SALVE. CERAT DE BLANC DE BALEINE, (*Fr.*) SIMPLE CERATE, (P. E.) CERATUM ALBUM, (P. L. 1745.) C. SPERMATIS CETI, (P. L. 1788.) CERATUM CETACEI, (P. L. 1809, 1824, 1836.) *Prep.* Spermaceti ℥ij; white wax ℥viii; olive oil 1 pint. Melt together and stir assiduously until cold. *Use.* As a soft cooling dressing.

Remarks. As soon as the materials are melted, they should be moved from the fire, strained into a clean vessel, and stirred until cold. To facilitate the cooling, the vessel may be placed in cold water or a current of cold air. This will render the product both whiter and finer than when allowed to cool by itself. The operation of melting should be performed in a water bath. On the large scale

lard or suet is substituted for oil, by which means less wax is required. The following is a good form where a cheap article is wanted.

II. Clarified mutton suet 5½ lbs.; white wax and spermaceti, of each ¾ lb. As above.

CERATE, SULPHUR. (CERATUM SULPHURATUM, P. Cod.) Washed sulphur 2 parts; cerate of Galen 7 parts; almond oil 1 part. Mix.

CERATE, SULPHURET OF MERCURY. (CERATUM RUBRUM, P. Cod.) Yellow wax, lard, and yellow resin, of each ℥j; red sulphuret of mercury gr. xxx. Mix.

CERATE, ZINC, AND LYCOPODIUM. (CERATUM ZINCI CUM LYCOPODIO, Hufeland.) Simple cerate ʒiv; oxide of zinc and lycopodium, in powder, of each gr. xv. Mix.

CERIUM. A metal discovered in 1803 by Hisinger and Berzelius, in a mineral named cerite. It is obtained in combination with a metal called by Mosander Lantanium. The mixed oxides may be procured by dissolving calcined and powdered cerite in nitro-muriatic acid, filtering, neutralizing with pure potassa, and then precipitating with tartrate of potassa. The powder that falls down is next washed and calcined.

The mixed oxides may be separated by solution in nitric acid, evaporation, and calcination. The mass previously powdered is then to be digested in water containing 2% of nitric acid; the undissolved portion is the oxide of cerium. The solution contains the *oxide of lantanium*, which may be obtained as a carbonate by adding a solution of carbonate of potassa.

The combination of these metals is but little known, and is now the subject of investigation by several eminent foreign chemists. Various compounds of these metals with the acids, sulphur, and chlorine have been formed.

CETENE. A colorless oily-looking liquid, obtained by repeatedly distilling ethal with glacial phosphoric acid. It is inflammable and soluble in alcohol and ether.

CETINE. *Syn.* PURE SPERMACETI. *Prep.* Dissolve spermaceti in boiling alcohol, and collect the crystals that deposite on cooling. *Prop.* Bright pearly crystals; melts at 120°; sublimes at 670°.

CHAIRS. The black leather work of chairs, settees, &c., may be restored by first washing off the dirt with a little warm soap and water, and afterwards with clean water. The brown and faded portions may now be restained by means of a little black ink, or preferably *black reviver*, and when this has got thoroughly dry, they may be touched over with white of egg, strained and mixed with a little sugar-candy. When the latter is nearly dry, it should be polished off with a clean dry brush.

A similar process will revive ladies' and gentlemen's dress boots and shoes.

CHALK. *Syn.* EARTHY CARBONATE OF LIME. Perhaps there is no one thing better known, or more universally distributed throughout England, than chalk. It is here largely used in the manufactures, the arts, and in medicine; and it forms an important geological feature of the country. It was the hills of chalk, the white cliffs of England, that conferred on it the name of Albion, (from *albus* or *albens*, white.) The chalk formation ranges over a great portion of the country, and in many cases obtains an elevation of nearly 1000 feet above the level of the sea. There are various kinds of chalk, principally distinguished by their color.

CHALK, PRECIPITATED. *Syn.* CRETA PRECIPITATA. *Prep.* (*Calcis Carbonas Precipitatum*, P. D.) Add a solution of carbonate of soda in 6 times its weight of water, to another of muriate of lime. Wash the precipitate repeatedly with distilled water.

Use. Precipitated chalk is ordered by the Irish College to be used in the preparation of "quicksilver with chalk." It is also frequently used as an ingredient in aromatic confection, cretaceous tooth-powder, &c., and is preferable in every case where chalk is ordered, and expense is not an object.

CHALK, PREPARED. *Syn.* CRETA. CALCIS CARBONAS FRIABILIS, (P. L.) FRIABLE CARBONATE OF LIME, (P. E.) CRETA ALBA, (P. D.) *Prep.* Rub chalk ℔j with sufficient water, added gradually, until reduced to a very fine powder; then put this into a large vessel with water, agitate well, and, after a short interval, pour off the supernatant water, *still turbid*, into another vessel, and let the suspended powder subside. In the same way shells are prepared, after being first freed from impurities, and washed with boiling water (P. L.)

Remarks. On the large scale the chalk is ground in mills, and the deposite made in large reservoirs. It is now seldom prepared by the druggist.

Use. Prepared chalk is used in medicine as an absorbent, antacid, and desiccant. It forms a valuable dusting powder in excoriations, ulcers, &c., especially in children. It is administered in dyspepsia, heartburn, acidity of the stomach, &c. In diarrhœa, depending on acidity or irritation, it is very serviceable, either alone, or combined with aromatics, astringents, or opium. *Dose.* 10 grs. to a spoonful. The precipitated chalk is preferable when it can be obtained pure, and either that or the prepared chalk must alone be used in medicine. The latter is, however, the cheaper of the two, and is consequently the one more generally used.

Pur. Precipitated chalk is frequently adulterated, and, in many cases, the article sold as such does not contain *one particle* of carbonate of lime. The following extract from a letter published in the "Annals of Chemistry," will throw some light on this subject. The truth of Mr. Bartlett's assertions I can testify to. "An article has been offered and purchased by both wholesale and retail druggists, (in one instance, I believe, to the extent of a ton weight,) under the name of precipitated chalk, at 8*d.* or 10*d.* per lb. instead of 1*s.* 4*d.* or 1*s.* 6*d.*, the price of the genuine article. This article appears beautifully white and flocculent, having all the appearance of the genuine, but is nothing more than *pure sulphate of lime.*" "It is well known that the carbonic acid gas of the soda-water manufacturer is obtained from whiting, and that it is disengaged therefrom by sulphuric acid. A short time since it was inquired of us to what purpose the pappy residuary mass of sulphate of lime and excess of whiting could be applied in

chemistry? At the time we were unable to furnish a satisfactory reply; the impression of our querist being that, on account of the secrecy observed in removing it, he had no doubt the uses to which it could be applied involved a good profit. We think Mr. B.'s letter may be received as a clue to the uses of this residue. Creta precipitata should be entirely soluble in acetic acid, with effervescence; the sulphate of lime, on the contrary, is insoluble." (Ann. Chem. and Pract. Pharm.)

The following are the tests of purity mentioned in the London Phar.:—"Entirely soluble in dilute muriatic acid, with effervescence. After this solution has been boiled, no precipitate is produced when ammonia is dropped in."

CHAMBERLAIN'S RESTORATIVE PILLS. A quack medicine, composed of cinnabar, sulphur, and sulphate of lime, made into pills with mucilage.

CHAMBERLIGHT, IMPROVED. Take a common cylindrical ointment pot, a 2 oz.-size in the winter, (in the summer a smaller one;) fill this with any kind of fat, as the waste fat from the kitchen for instance. Trim by about ½ an inch of the common wax-wick, sold at the tallow-chandler's, simply stuck into a thin slice of a wine-bottle cork, upon which place a strip of stout filtering paper, about half the diameter of the cork in breadth, and a diameter and a half in length. It need not be quite so broad, but it must be at least the length stated. The reason for using the bibulous paper is, that it feeds the wick properly; without it, or some such contrivance, it will not burn. Remove with the handle of a teaspoon sufficient of the fat to allow the cork to be a little below the surface, and then place the fat so removed over the cork and paper, neatly spreading it to make an even surface. The light is now prepared. (Ann. of Chem.)

CHAMOMILE DROPS. *Prep.* Dissolve 1 oz. of essential oil of chamomile in 1 pint of rectified spirit of wine. *Use.* As a stomachic and stimulant. *Dose.* 5 to 30 drops; ½ an oz., shaken with about 1 pint of pure water, forms an excellent chamomile water.

CHAPPED HANDS AND LIPS. The application of a little cold cream, pomatum, spermaceti ointment, lard, or any similar article, will generally prevent chaps and chilblains on the lips and hands. Persons employed in oil works, or about oil, and who have consequently their hands continually imbued therewith, never suffer from these things. A little oil or unguent of any kind, well rubbed over the hands on going to rest, (removing the superfluous portion with a cloth,) will not only preserve them from cold, but render them beautifully soft and white. It is said that a favorite actress, celebrated for the beauty of her hands, covers them nightly with the flare of a calf or lamb with the fat attached, over which is drawn a glove of leather. (What inconvenience and even pain will not persons suffer to gratify their pride!)

CHARCOAL. A peculiar and well-known black substance, obtained from organic matter, by calcination in close vessels. There are two kinds of charcoal met with in commerce, viz., animal (bone) and vegetable, (wood.)

I. (*Animal charcoal.*) The preparation of this kind of charcoal has been already explained.

II. (*Vegetable charcoal.*) *Prep.* This is prepared for fuel by cutting pieces of wood, of from 1 to 3 or 4 inches in diameter, into lengths, varying from 1 to 2 or 3 feet, forming them into a conical pile, covering them with turf or clay, to exclude the air, leaving only 2 or 3 small holes at the bottom for lighting the wood, and a few others still smaller at top to admit the escape of the smoke. The wood is now kindled, and the combustion allowed to proceed slowly for 8 or 10 days, more or less, until the volatile matter of the wood be driven off, when the air holes are stopped up with clay, and the further combustion of the pile arrested. The whole is then allowed to remain until cold, before it is broken up. In case of very high winds occurring during the carbonization of the wood, the holes to windward are stopped up with clay or earth, to prevent the mass burning too rapidly.

The charcoal employed in the manufacture of gunpowder is burnt in close iron cylinders, and has hence received the name of "cylinder charcoal." For this and other nice purposes, it is essential that the last portion of the tar and vinegar be suffered to escape, and reabsorption of the crude vapors prevented, by cutting off the communication between the cylinders and the condensing apparatus, as without this precaution, on the fire being withdrawn, this would certainly take place, and the product be much reduced in quality. The dogwood, alder, and willow are those used for making charcoal at Waltham Abbey. The Dutch white willow, and after that the Huntingdon willow, are said to yield the best charcoal for gunpowder. (Lieut.-Col. Moody.)

It has been stated, that in charring wood, a portion of it is sometimes converted into a species of pyrophorous. Perhaps this might have been the cause of the late dreadful explosion at the above works.

Uses, &c. Charcoal is used as a fuel, and in metallurgy for tempering metals. Reduced to powder, it is used to surround vessels and bodies required to retain their heat for some time. A coating of charcoal formed on piles and stakes of wood, by charring them, is frequently adopted to promote their preservation, as it is unchangeable by air and moisture. Powdered fresh-burnt charcoal restores tainted meat and putrid water, decolors vegetable solutions, and withdraws lime from sirups filtered through it. For both these purposes animal charcoal is best.

Charcoal varies in its qualities according to the substance from which it is prepared; that of the soft woods, as the willow or alder, is best for crayons, and for making gunpowder; that of the harder woods is used for fuel, or for a support for substances exposed to the flame of the blowpipe. Charcoal of animal substances has the greatest clarifying power. That made by a low red heat, not exceeding cherry red, has a dull surface, and is best for clarifying liquids, and probably for making gunpowder, and for fuel. If the heat be carried beyond this point, the charcoal acquires a brilliant surface, and is considerably inferior for clarifying, and probably for every other use.

Oak, beech, and hazel charcoal are those com-

monly sold in London for fuel. Willow charcoal is also occasionally found mixed therewith, and is frequently picked out for crayons, polishing copper-plates, for grinding, to make tooth-powders, poultices, &c. Chesnut charcoal is preferred by smiths for forging, as it not only burns slowly, but deadens as soon as the blast ceases. Areca-nut charcoal is preferred as a dentifrice, but that from the willow is commonly sold for it.

In medicine, charcoal is principally used as an antiseptic or disinfectant, either in the form of powder or made into a poultice. It has been given internally in dyspepsia, diarrhœa, dysentery, and heartburn, with advantage. *Dose.* 10 grs. to a tablespoonful, ad libitum. An ointment made with lard and charcoal has been employed in some skin diseases.

Ant. In cases of asphyxia, produced by respiring the fumes of burning charcoal, the treatment is similar to that described under carbonic acid.

If the person has been only so much exposed to the vapor as to stagger, on coming into the fresh air it goes off; but the head remains affected. When the exposure has been so long that sleepiness comes on, the patient should be immediately bled, cold water thrown upon the head, &c., and stimulating applications to the feet. There have been instances of recovery by these means, even when respiration had ceased, and some part of the animal heat had been lost. If life does not quickly return it will be highly proper to attempt artificial respiration. (See Asphyxia.) The most simple excitant in this species of asphyxia, is the passage into the nasal fossæ of a feather dipped in common vinegar. It is the means which has always first caused the muscular contractions indicating revival. (Gabriel Pelletan.)

Gilders, jewellers, copper-plate printers, braziers, &c., who use small open fires of burning charcoal, should endeavor to create a draught of air to carry off the fumes, and should take care to keep to "*windward*," (as sailors call it,) by which means they will avoid them. Vessels containing milk of lime have been employed to absorb the gas, but their action must necessarily be very limited. The only certain remedy is thorough ventilation. This should be adopted, even at slight personal inconvenience in other respects.

CHARCOAL CRAYONS. *Prep.* Saw the finest-grained, softest, and blackest pieces of charcoal, into slips of the size required, put them into a pipkin of melted wax, and allow them to macerate over a slow fire for half an hour, then take them out and lay them on blotting-paper to dry.

Remarks. The above process may also be employed for red and black chalk. Drawings made with these crayons are very permanent, and if warmed slightly on the wrong side, the lines will adhere and become as durable as ink. These crayons may also be made by simply shaping the charcoal with a knife. Willow charcoal should be used for this purpose.

CHARCOAL, LARDNER'S PREPARED. *Prep.* Mix well together 1 oz. of finely-ground charcoal with 3 oz. of prepared chalk. *Use.* As a tooth-powder.

CHARRING, SURFACE. The operation by which the surface of wood is carbonized, to prevent its decay on exposure to air and moisture. *Stakes and piles* are generally thus treated before they are driven into the ground. *Casks* are charred on the inside by coopers when they are intended to hold water. In both these cases the fire is applied directly to the wood. A new method has, however, been lately employed with apparent success. This consists in washing the wood with the strongest oil of vitriol. In this way, not only the outer surface, but the surface of all the cracks and holes, gets carbonized, which is not the case when heat is employed.

CHEESE. The curd of milk compressed into a solid mass.

Qual., &c. This well-known substance has been objected to as an article of diet, but without sufficient reason. That the inferior kinds of cheese are not very digestible must be acknowledged, and when eaten in quantity may overload the stomach; but when the quality is good, and the digestive organs are in a healthy condition, it must evidently prove not only wholesome but very nutritious. Like all other food, cheese digests more readily when well masticated, and the neglect of this precaution is one reason why it frequently disagrees with delicate stomachs. It is rendered more agreeable to most palates by toasting, but becomes less digestible by that operation. The basis of cheese is caseine or coagulated curd, a proteine substance; it therefore cannot fail to prove nutritious, provided it be properly digested. Cheese-curd, carefully freed from water and milk by expression, and the addition of salt, is a mixture of caseine and butter; it contains all the phosphate of lime, and part of the phosphate of soda, of the milk. (Liebig.) When taken as a condiment, especially when rich and old, it powerfully promotes the secretion of the saliva and gastric juice, and thereby aids the stomach in performing its proper functions.

Principles of Cheesemaking. When any vegetable or mineral acid is added to milk, and heat applied, a coagulum is formed, which, when separated from the liquid portion, constitutes cheese. Neutral salts, earthy and metallic salts, sugar, and gum Arabic, as well as some other substances, also produce the same effect; but what answers best is *rennet*, or the mucous membrane of the last stomach of the calf. Alkalis dissolve this curd at a boiling heat, and acids again precipitate it. The solubility of cheese in milk is occasioned by the presence of alkaline phosphates and of free alkalis. In fresh milk these may be readily detected by the property it possesses of restoring the color of reddened litmus paper. The addition of an acid neutralizes the alkali, and so precipitates the curd in an insoluble state.

"The acid indispensable to the coagulation of milk, is not *added* to the milk in the preparation of cheese, but it is *formed in the milk* at the expense of the milk-sugar present. A small quantity of water is left in contact with a small quantity of a calf's stomach for a few hours, or for a night; the water absorbs so minute a portion of the mucous membrane as to be scarcely ponderable; this is mixed with milk; its state of transformation is communicated, (and this is a most important circumstance,) *not to the cheese but to the milk-sugar*, the elements of which transpose themselves into lactic acid, which neutralizes the al

kali, and thus causes the separation of the cheese. By means of litmus paper the process may be followed and observed through all its stages; the alkaline reaction of the milk ceases as soon as the coagulation begins. If the cheese is not immediately separated from the whey, the formation of lactic acid continues, the fluid turns acid, and the cheese itself passes into a state of decomposition.

"When cheese-curd is kept in a cool place, a series of transformations take place, in consequence of which it assumes entirely new properties; it gradually becomes semi-transparent, and more or less soft throughout the whole mass; it exhibits a feebly acid reaction, and develops the characteristic caseous odor. Fresh cheese is very sparingly soluble in water, but after having been left to itself for two or three years, it becomes (especially if all the fat be previously removed) almost completely *soluble in cold water*, forming with it a solution, which, like milk, is coagulated by the addition of the acetic or mineral acids. The cheese, which while fresh is insoluble, returns during the maturation, or ripening, as it is called, to a state similar to that in which it originally existed in the milk. In those English, Dutch, and Swiss cheeses which are nearly inodorous, and in the superior kinds of French cheese, the caseine of the milk is present in its unaltered state. The odor and flavor of the cheese is owing to the decomposition of the butter; the non-volatile acids, the margaric and oleic acids, and the volatile butyric acid, capric and caproic acids, are liberated in consequence of the decomposition of glycerine, (the sweet principle of oils, or, as it might be termed, the sugar of oils.) Butyric acid imparts to cheese its characteristic caseous odor, and the differences in its pungency or aromatic flavor depend upon the proportion of free butyric, capric, and caproic acids present.

"The transition of the insoluble into soluble caseine depends upon the decomposition of the phosphate of lime by the margaric acid of the butter; margarite of lime is formed while the phosphoric acid combines with the caseine, forming a compound soluble in water.

"The bad smell of inferior kinds of cheese, especially those called meager or poor cheeses, is caused by certain fetid products containing sulphur, and which are formed by the decomposition or putrefaction of the caseine. The alteration which the butter undergoes, (that is, in becoming rancid,) or which occurs in the milk-sugar still present, being transmitted to the caseine, changes both the composition of the latter substance and its nutritive qualities.

"The principal conditions for the preparation of the superior kinds of cheese, (other obvious circumstances being of course duly regarded,) are *a careful removal of the whey, which holds the milk-sugar in solution, and a low temperature during the maturation or ripening of the cheese.*" (Liebig's Lectures.)

Cheese differs vastly in quality and flavor, according to the method employed in its manufacture, and the richness of the milk of which it is made. It is thought by some that the pasture, or the food on which the cows feed, exercises considerable influence upon the quality of the cheese; but this influence, if any, is very slight and subordinate. As the cheese made on the same farm does not vary in any important degree, whether made in winter or summer, while the food must differ considerably from the luxuriance of vegetation at the one period, and its scantiness and the absence of flowering plants at the other. So long as the cows receive sufficient food of good quality, the precise description appears of little consequence. Much depends upon the richness of the milk, or the quantity of cream it contains, and consequently, when a superior quality of cheese is desired, cream is frequently added. This plan is adopted in the manufacture of Stilton cheese. The addition of a pound or two of butter to the curd for a middling size cheese, will also vastly improve its quality. To ensure the richness of the milk, it is of course necessary that the cow be not only properly fed, but be of a good breed, such as are commonly known as good milkers. The breeds cultivated in Alderney, Cheshire, Gloucester, North Wiltshire, Chedder, and Guernsey, deserve notice in this respect.

The taste and odor of cheese vary in almost every county of England, and even in portions of the same county, where the herbage is similar; it is therefore evident that the mode of manipulating and the quality of the milk must be the chief causes of the difference. Stilton, Chedder, Cheshire, and Gloucester, are among the most celebrated places or districts for its manufacture in England.

Cheese is generally made from the milk of cows, but occasionally from that of ewes, and sometimes, though more rarely, from the milk of goats.

Process of Cheesemaking. The materials employed in making cheese are *milk and rennet. Rennet* is the stomach of the calf, and may be used either fresh, or salted and dried. It is generally kept in the latter state, for the sake of preserving it good. The stomach is taken from the calf as soon as killed, and after being cleared of the curd always found in it, it is well salted both on the outside and in, and after draining for a sufficient time, it is stretched out upon a stick and dried. *The milk* may be of any kind, from the poorest skimmed-milk to that rich in cream, according to the quality of the cheese required. The poorest kind of cheese is made from the former, and the finer from the latter, to which cream is frequently added.

The materials being ready, the greater portion of the milk is put into a large tub, and the remainder sufficiently heated to raise the whole quantity to the temperature of new milk. The whole is then whisked together, the rennet added, and the tub covered over. It is now allowed to stand until completely turned, when the curd is struck down several times with the skimming-dish, after which it is allowed to subside. The vat covered with cheese-cloth is next placed on a "horse or ladder" over the tub, and filled with curd by means of the skimmer; the curd is pressed down with the hands, and more added as it sinks This process is repeated until the curd rises to about 2 inches above the edge. The cheese thus partially separated from the whey is now placed in a clean tub, and a proper quantity of salt added, or the salt is added to it without removing it from the vat, after which a board is placed over and under it, and pressure applied for 2 or 3 hours.

The cheese is next turned out and surrounded by a fres : cheese-cloth, and pressure again applied for 8 or 10 hours, when it is commonly removed from the press, salted all over, and pressed again for 15 to 20 hours. The quality of the cheese especially depends on this part of the process, as if any of the whey be left in the cheese, it will not keep, but will rapidly become bad-flavored. Before placing it in the press the last time, the edges should be pared smooth and sightly. It now only remains to wash the outside of the cheese in warm whey or water, wipe it dry, and color it with annotto as is usually done.

There are several methods of collecting the curd adopted, and as the flavor of the cheese varies accordingly, it is as well to notice them. One way is to break the curd early, and to remove the whey as soon as possible; another plan is to gather it with the hands very gently towards the sides of the tub, letting the whey run off through the fingers until it becomes cleared, and ladling it off as it collects. A third method is to remove it as quickly as possible with the curd-skimmer. Of these the second plan is said to be the best, as it preserves the oily particles, many of which are lost by the other methods.

The cheese being made, it now only remains to place it in a proper situation to mature or ripen. In England a *cool, and slightly damp cellar*, is commonly regarded as the best to bring it forward. The temperature should on no account exceed 50° at any portion of the year, but an average of about 45° is preferable when it can be procured. A place exposed to sudden changes of temperature is unfit for storing cheese. "The quality of Rochefort cheese, which is prepared from sheep's milk, and is very excellent, depends exclusively upon the places where the cheeses are kept after pressing and during maturation. These are cellars, communicating with mountain grottoes and caverns, which are kept constantly cool, at about 41° to 42° Fahr., by currents of air from clefts in the mountains. The value of these cellars as storehouses varies with their property of maintaining an equable and low temperature. Giron (Ann. de Chim. et Phys. xlv. 371) mentions that a certain cellar, the construction of which had cost 480*l*., (12,000 francs,) was sold for 8,600*l*., (215,000 francs,) being found to maintain a suitable temperature, a convincing proof of the importance attached to temperature in the preparation of these superior cheeses." (Liebig's Lectures.)

It will thus be seen that very slight differences in the materials, the preparation, or the storing of cheese, will materially influence the quality and flavor. The richness of the milk,—the addition to or subtraction of cream from the milk,—the separation of the curd from the whey with or without compression,—the salting of the curd,—the collection of the curd, either whole or broken, before pressing,—the addition of coloring matter, as annotto or saffron, or of flavoring,—the place and method of storing,—and the length of time allowed for maturation, all tend to alter the taste and odor of the cheese, in some or other particular, and that in a way readily perceptible to the refined palate. The nature of the pasture or the food on which the cows are fed, as well as their particular breed, no doubt also tends in some slight degree to promote the same diversity of flavor and quality. No other alimentary substance appears to be so materially affected by slight variations in the quality of the materials from which it is made, or by such apparently trifling differences in the methods of preparing it.

Var. There are several varieties of cheese met with in trade, differing from each other in quality or flavor; and these are generally distinguished by the names of the places where they have been manufactured, and sometimes, though more rarely, by their flavor, or the milk from which they are manufactured. Three divisions may however be made, depending upon the quality of the materials, each of which is well marked, and to one or the other all kinds of cheese belong. These are *skimmed-milk, raw-milk*, and *cream cheeses*, the names of which respectively express the materials of which they are made. The following are the principal cheeses met with in Europe.

Brickbat cheese, made in Wiltshire of new milk and cream. This name is given to it from its being made into forms resembling brickbats.

Chedder cheese, named after the place where it is made. This is a fine kind of cheese, with a spongy appearance, the eyes or vesicles of which contain a rich oil. It is made up into round thick cheeses of considerable size.

Cheshire cheese. The best Cheshire cheese is made of new milk without skimming, the morning's milk being mixed with that of the preceding evening, previously warmed, so that the whole may be brought to the heat of new milk. To this the rennet is added, in less quantity than is commonly used for other kinds of cheese. On this point, much of the flavor and mildness of the cheese is said to depend. A piece of dried rennet, of the size of half-a-crown, put into a pint of water over night, and allowed to stand until the next morning, is sufficient for 18 or 20 gallons of milk. The curd is next broken down and separated from the whey, after which it is put into a cheese vat and pressed very dry. It is next broken very small with the hands, and mixed with a proper quantity of salt, and about half its weight of curd, from yesterday's batch, kept for the purpose. The mixed curds are now pressed tightly with the hands, into a cheese-vat, previously lined with cheese cloth, pressed for 4 or 5 hours, then taken out, turned, and again put into the press and left for the night. It is taken out next morning, well salted, and left until the salt is quite melted, when it is wiped dry, placed in a dry, cool situation, and turned every day until it becomes fit for the market.

"If the milk be set together very warm, the curd will be firm: in this case, the usual mode is to take a common case-knife, and make incisions across it, to the full depth of the knife's blade, at the distance of about 1 inch; and again crosswise in the same manner, the incisions intersecting each other at right angles. The whey rising through these incisions is of a fine pale green color. The cheese-maker and two assistants then proceed to break the curd: this is performed by their repeatedly putting their hands down into the tub; the cheese-makers, with the skimming-dish in one hand, breaking every part of it as they catch it, raising the curd from the bottom, and still breaking

it. This part of the business is continued till the whole is broken uniformly small; it generally takes up about 40 minutes, and the curd is then left covered over with a cloth for about half an hour to subside. If the milk has been set cool together, the curd, as before mentioned, will be much more tender, the whey will not be so green, but rather of a milky appearance." (Cheshire County Agricultural Report.)

Cream cheese. This is either made of the "strippings," (the last of the milk drawn from the cow at each milking,) or of a mixture of milk and cream. It is usually made up into small pieces, and a gentle pressure, as that of a 2 or 4 lb. weight, applied to press out the whey. After twelve hours, it is placed upon a board or wooden trencher, and turned every day, until dry. In about three weeks, it will be ripe. Nothing but raw cream, turned with a little rennet, is employed, when a *very rich* cheese is wanted. A little salt is generally added, and frequently a little powdered lump sugar. The vats employed for cream cheeses are usually square, and of small size.

Cottenham cheese, named from the town where it is made, is a species of cream cheese, superior to Stilton, from which it also differs in shape, being flatter and broader than the latter. Its superiority is said to be derived from the rich grasses growing on the fens of Cambridgeshire.

Derbyshire cheese is a small rich variety, of a pale color, very similar to the following:

Dunlop cheese, named after a town in Ayrshire, where it was originally made. It is very rich, white, and buttery, and is made up into round forms, weighing from ¼ cwt. to ½ cwt. It is now made very generally throughout the whole of Scotland.

Dutch cheese. This is very commonly met with in England, and is readily distinguished by its globular form. The cheeses made at Edam are very highly salted; those made at Gouda are less so. The common size of these cheeses is from 5 to 14 lbs.

French cheese. The Rochefort and the Neufchatel are the most esteemed.

German cheese. The only kind made in Germany of any celebrity, is the *Westphalian,* which derives its peculiar flavor from the curd being allowed to become partially putrid before being pressed. It is made up into small balls or cylinders, of about a pound weight, somewhat resembling in shape the pounds of butter in some parts of the west of England.

Gloucester cheese. There are two varieties of this cheese: *the single,* made of milk deprived of part of its cream, and *the double,* made of milk retaining the whole of the cream. The best kind has a fine mild taste; a semi-buttery consistence, without being friable, and is made up into large round flattish forms.

Green or sage cheese is made from milk previously mixed with the juice or an infusion or decoction of sage leaves, to which some marygold flowers and parsley are frequently added.

Lincolnshire cheese is made of new milk and cream, and formed into pieces about 2 inches thick. It is very soft, and without great care, will not keep over two months. Some persons sprinkle dry salt over them, when they will keep better.

Norfolk cheese. This is remarkable for the curd being dyed yellow, with annotto or saffron. It is of very good but not superior quality, and usually weighs from ¼ to ½ cwt.

Neufchatel cheese. After Rochefort cheese, this is the best manufactured in France. It is made of cream, and seldom exceeds 5 or 6 oz. in weight.

Parmesan cheese. This is made at Parma, and in other parts of Lombardy. Its peculiar flavor is said to arise from the luxuriance of vegetation in that part of Italy, and from the great abundance of aromatic flowers in the pastures. It is more probable, however, that the application of heat to the curd of the milk, to harden it, as is the common practice in Lombardy, is the true cause of its flavor. The following method is said to produce a cheese equal to the best Parmesan:

"Let the day's milk be heated to the degree of 120° of Fahrenheit, then removed from the fire until all motion ceases, put in the rennet, allow an hour for the coagulation, after which set the curd on a slow fire until heated to 150°, during which the curd separates in small lumps. A few pinches of saffron are then thrown in, together with cold water sufficient to reduce it instantly to a bearable heat, when the curd is collected by passing a cloth beneath it, and gathering it up at the corners. Place the curd in a circle of wood without a bottom; lay it on a table covered by a round piece of wood, pressed down by a heavy stone. The cheese will acquire sufficient consistence in the course of a night to bear turning, when the upper side is to be rubbed with salt, and continued alternately for forty days."

"In Italy, the outer crust is next cut off, and the new surface varnished with linseed oil; but that may well be omitted, as well as coloring one side of it red."

Polish cheese. This is generally of very inferior quality, and made in imitation of English cheese.

Rochefort cheese. This is made of ewe's milk, and is the best kind prepared in France. It resembles Stilton, but is scarcely of equal richness or quality. By kneading the gluten of wheat with a little salt, and a small portion of a solution of starch, it acquires the taste, smell, and unctuosity of cheese; so that after it has been kept a certain time, it is not to be distinguished from the celebrated Rochefort cheese, of which it has all the pungency. (Roulle.) See the remarks on the Principles of Cheesemaking, above.

Russian cheese. This is generally of a very inferior kind. The best sort is that made in imitation of English cheese; the commoner kinds merely consist of salted curd, placed in a bag and wrung dry, by two persons twisting the ends in opposite directions. It is usually not only bad tasted, but dirty.

Slipcoat or soft cheese is a very rich white cheese, somewhat resembling butter, made for present use.

Stilton cheese, named after the town where it was originally made, is at once the richest and finest variety of cheese manufactured in England. It is prepared from raw milk, to which cream taken from other milk is added. Its shape is peculiar, being generally twice as high as it is broad. It is generally twice the price of Cheshire or dou-

ble Gloucester. Like wine, this cheese is vastly improved by age, and is therefore seldom eaten before it is two years old. A spurious appearance of age is sometimes given to it by placing it in a warm damp cellar, or by surrounding it with masses of fermenting straw, or rotten cow-dung.

Suffolk cheese is made from skimmed milk, and is usually shaped into round flat forms, weighing from 24 lbs. to 30 lbs. each. It much resembles the skimmed or "scald" milk cheese made in Devonshire.

Swiss cheese. The principal cheeses made in Switzerland are the Gruyère, or Jura, and the *Schabzieger*, or *green cheese.* The latter is flavored with melilot.

Wiltshire cheese resembles poor Cheshire or Glo'ster. The outside is generally covered with red paint, made by mixing up ruddle or red ochre with whey, and laying it in with a brush.

Yorkshire cheese is a fine variety of cream cheese, but will not keep.

Concluding Remarks. It is surprising that cheese is not more frequently made an article of domestic manufacture, especially by housewives resident in the country. The operations of cheese-making are all exceedingly simple, and not at all laborious, and will, in most cases, amply repay the outlay for the milk. With the peasantry, who can usually procure a few gallons of milk from the houses of the farmers for whom they work, it really appears a want of common foresight, not to provide themselves with a few pounds of this wholesome and nutritious article, which is looked upon by some of those roughly-fed children of the soil, as a luxury beyond their reach. In a family where cheese is generally relished by the majority of the members, it becomes quite as necessary to have home-made cheese as home-made bread, and there is scarcely a portion of the United Kingdom where milk may not be obtained, during the summer months, at such a price as to render it important in a pecuniary point of view. Besides, cheese is not unfrequently colored with stains and pigments which are injurious, and even poisonous. Several persons have nearly lost their lives, from eating cheese colored with annotto, for instance. This dye is commonly adulterated with red-lead, so that the farmer (cheesemaker) may very innocently introduce a dreadful poison, when he only intends to improve the color. By making our own cheeses, the liability to such an accident is avoided.

When a whole cheese is cut, and the consumption small, it is generally found to become unpleasantly dry, and to lose flavor before it is consumed. This is best prevented by cutting a sufficient quantity for a few days' consumption from the cheese, and placing the remainder in a cool place, rather damp than dry, spreading a thin film of butter over the cut surface, and covering it with a cloth to keep off the dirt. This removes the objection existing in small families against purchasing a whole cheese at a time. The common practice of buying small quantities of cheese should be avoided, as not only a higher price is paid for any given quality, but there is little likelihood of obtaining exactly the same flavor twice running. Should cheese become too dry to be agreeable, it may be used for stewing, or when grated cheese is wanted.

Toasted cheese is much relished by some persons, but is seldom met with well prepared. The following has been handed to the writer by the cook of a certain nobleman who prides himself on his gustful appetite. Cut the cheese into slices of moderate thickness, and put them into a tinned copper saucepan, with a little butter and cream, simmer very gently until quite dissolved, then remove it from the fire, allow it to cool a little, and add some yelk of egg, well beaten; make it into a shape, and brown it before the fire.

CHELTENHAM SALTS. *Prep.* Glauber salts 1 oz.; Epsom salts ¾ oz.; culinary salt a teaspoonful; sulphate of iron 2 grs.; reduce them separately to fine powder, then mix them.

II. Glauber salts and Epsom salts, of each 28 lbs.; common salt 7 lbs.; sulphate of iron 1¼ oz.; mix.

Remarks. The above salts must be dried in an oven, or over the fire, before reducing them to powder. The Glauber's should be dried by itself, as it liquefies when slightly heated. Cathartic and tonic. *Dose.* ½ oz. to 1½ oz.

CHELSEA PENSIONER. *Prep.* Gum guaiacum ¾ oz.; rhubarb ½ oz.; cream of tartar 2 oz.; flowers of sulphur 4 oz.; nutmegs 2 in number, (all in powder;) honey 1½ lb.; make them into a confection by beating them together in a mortar.

Remarks. The dose is two tablespoonfuls, night and morning, in rheumatism. The name is said to have been given to it from the circumstance of a Chelsea pensioner having cured Lord Amherst with it.

CHILBLAIN. An inflammatory swelling, of a purple or lead color, produced by the action of cold. Children, especially those of a scrofulous habit, and elderly persons, are generally most liable to chilblains. The common cause of chilblains is holding the hands or feet to the fire, after exposure to cold. The sudden change of temperature partially destroys the vitality, and prevents the proper flow of blood through the part. The best preventives of chilblains are woollen socks or stockings, good waterproof shoes, woollen gloves, exercise, and friction. *When chilblains have once formed*, the best treatment is friction, with stimulants, as spirits of wine and camphor, turpentine, opodeldoc, dilute spirits, camphorated oil, &c. Linnæus recommends bathing the part with dilute muriatic acid, just strong enough to faintly prick the skin. When the inflamed parts have ulcerated, they are commonly called *kibes.* In this state they should be dressed with a little resin cerate, or elemi ointment, and if fungous granulations appear, they must be removed by touching them with nitrate of silver or blue vitriol.

CHILBLAINS, LOTIONS FOR, (POPULAR.) I. Dissolve white copperas 1 oz. in water 1 pint, and occasionally apply it to the affected parts.

II. Dissolve sal ammoniac 1 oz. in vinegar ½ pint; as above.

III. Mix compound soap liniment 2 oz. with tincture of Spanish flies 1 oz.; as above.

IV. Vinegar and spirit of wine, (or rum,) of each ½ pint; sal ammoniac, in powder, 1 oz.; mix and shake until the latter dissolves.

V. Spirits of salts 1 oz.; water ½ pint; mix; as above.

CHILBLAINS, OINTMENT FOR. *Prep.* Ointment of nitrate of mercury 1 oz.; camphor 1 dr.; oil of turpentine 2 drs.; oil of olives 4 drs.; mix well together. To be applied, by gentle friction, 2 or 3 times daily.

II. Calomel and camphor, of each 1 dr.; spermaceti ointment 4 drs.; oil of turpentine 2 drs.; as last.

Remarks. All the preceding lotions and ointments are intended for chilblains before they break.

CHILBLAINS, RUSSIAN REMEDY FOR. A common remedy for chilblains among the peasants in Russia is the rind of perfectly ripe cucumbers, dried with the soft parts attached, and placed with the inner side, previously soaked in warm water, over the sore parts. Dumitriefsky confirms the efficacy of this remedy. (Med. Zeitung.)

CHIMNEYS ON FIRE may be readily extinguished in several ways, without having recourse to throwing water down them from the top, by which much damage is frequently done to the furniture in the rooms. One of the simplest methods is, to scatter a handful of flowers of sulphur over the dullest part of the burning coals, the mephitic vapors arising from which will not support combustion, and consequently extinguish the flames. *Another* method is, to shut the doors and windows, and to stop up the bottom of the chimney with a piece of wet carpet or blanket, throwing a little water or flowers of sulphur, or salt, on the fire immediately before doing so. By this means the draught is stopped, and the burning soot must be extinguished for want of air. If the chimney be stopped at top, instead of the bottom, the whole of the smoke must, of course, be driven into the apartment. If every fireplace were provided with a damper, or shutter of sheet-iron or tin plate, sufficiently large to choke it thoroughly, fires in chimneys would become of little consequence, as it would only be necessary to apply this damper to put them out.

CHINA, (CHOICE OF.) In purchasing china, glass, and earthenware, care should be taken to select those sets that in case of breakage can be readily matched. Peculiar or rare patterns should be avoided, for if any such be broken, it will generally be found very difficult and expensive, and frequently impossible, to replace them.

Cleaning. China (when very dirty) is best cleaned with finely-powdered fuller's earth and warm water, afterwards rinsing it well in clean water. A little clean soft soap may be added to the water instead of fuller's earth. The same plan is recommended for cleaning glass.

Packing. As there is considerable art in packing brittle hollow-ware, in such a way that it will stand exposure to the jolting, blows, and agitation of land-carriage, it is better, where it is of much value, or in quantity, to have it done by a person used to the job. A man, accustomed to packing such articles, may be readily procured at any glass-works, or china warehouse, for a trifling consideration.

CHINA-ROOT STARCH. A reddish-colored farina, procured from the smilax china.

CHINESE SHEET-LEAD. The Chinese employ large quantities of sheet-lead in packing their tea, which they make in the following way:—Melted lead is poured from a crucible upon a large flat stone, placed upon the ground, and immediately another stone is dashed upon the fluid lead, which is thus pressed out into a very thin plate or leaf. This is instantly removed, and the operation repeated as rapidly as possible. The rough edges of the plates are afterwards cut off, and then soldered together for use. The Chinese employ two men in this process; one to pour on the melted lead, and the other to work the stone. A similar method has been adopted for some years in England, to form the plates of zinc for galvanic batteries.

CHIRAYITINE, SULPHATE OF. The substance sold under this name is sulphate of quina. Chirayita yields no alkaloid, but merely a bitter matter.

CHLORAL. A substance prepared by the action of chlorine on alcohol.

Prep. Place anhydrous alcohol in a tubulated retort, and pass dry chlorine gas through it, at first in the cold, but afterwards with the application of a gentle heat. As soon as the chlorine passes undecomposed through the liquor at the boiling temperature, the process is complete. On cooling, the liquid in the retort solidifies, forming a crystalline mass of hydrated chloral. This must be melted by gentle heat, and agitated with thrice its volume of oil of vitriol, when, on increasing the heat a little, an oily stratum of impure chloral will rise to the surface. This must be removed, boiled for some time, to drive off some free hydrochloric acid and alcohol, and next distilled with an equal volume of oil of vitriol; lastly, it must be rectified from finely-powdered quicklime, stopping the process as soon as the surface of the lime becomes dry.

Remarks. The chlorine is best introduced by a tube inserted into the tubulature of the retort, and a long tube, bent upwards, should be connected with the beak to convey away the hydrochloric acid gas extricated, and to allow the volatilized alcohol and chloral to condense and flow back into the retort.

Prop. Chloral is an oily liquid, possessing an ethereal smell; it is soluble in alcohol, ether, and water, but its solution in the latter rapidly changes into a semi-solid crystalline mass of hydrate of chloral, soluble in a larger quantity of water. Chloral boils at 202°, and has a sp. gr. of 1·502.

CHLORATE. A compound of chloric acid with a base. The chlorates are very similar to the nitrates, both in their properties and composition. They are all decomposed at a red heat, metallic chlorides being formed, and oxygen gas given off. Like the nitrates, they deflagrate with inflammable substances, but with greater facility and violence. A mixture of this kind will detonate with a slight blow or friction. All the chlorates are soluble in water.

Tests. Rubbed with sulphur, or phosphorus, they explode violently; mixed with muriatic acid, and then with water, a liquid is formed, possessing bleaching properties. When heated, they evolve oxygen. Thrown on red-hot coals, they deflagrate like nitre. Sulphuric acid turns them orange red. The following simple method of testing the commercial chlorates has been proposed by M. Choron:

place supplied by hard suet or stearine, and frequently rosin. Lard is also very generally substituted for olive oil. The operation of melting the ingredients should be performed in a water or steam bath, and the liquid mass should be assiduously stirred until cold.

CERATE, BLISTERING. *Syn.* CERATE OF SPANISH FLIES. CERATUM CANTHARIDES. (P. L.) *Prep.* Spanish flies in fine powder ℥j; spermaceti cerate ℥vj; soften the cerate by heat, then carefully mix in the powdered flies.

Use. To keep blisters open, and as a mild stimulant. Its use is sometimes, however, attended by strangury and other disagreeable symptoms. A blister on the scalp, dressed for 4 days with this cerate, was followed by the head swelling to an alarming size, an œdematose erysipelas over the face and scalp to the occlusion of the eyes, and great fever. These symptoms were removed by the use of emollient fermentations and simple dressings. (A. T. Thompson.) Very probably the cerate contained euphorbium, which it derived from the powdered flies being adulterated with this substance. (See CANTHARIDES.)

CERATE, CALAMINE. *Syn.* CERATUM EPULOTICUM, (P. L. 1745.) CERATUM LAPIS CALAMINARIS, (P. L. 1788.) CERATUM CALAMINÆ, (P. L. 1836.) HEALING SALVE. TURNER'S CERATE. *Prep.* Prepared calamine (lapis calaminaris) and wax, of each lb. ss; olive oil f℥xvj. *Proc.* Mix the oil with the melted wax, and as soon as it begins to thicken, add the calamine and stir until cold.

Use. To dress excoriations, ulcers, burns, sore nipples, &c. It is drying and healing.

Remarks. On the large scale this cerate is usually made without a particle of wax. 4 lbs. of suet are melted with 3 lbs. of lard, and 3½ lbs. of calamine sifted in: the whole is then well mixed up for a few minutes, and after one minute's repose, it is poured off into another vessel, a little coarse sediment that has fallen to the bottom being left behind. It is then stirred until cold. In many cases nothing but lard and calamine are used.

CERATE, CALAMINE, (WITH MERCURY.) *Prep.* (CERATUM CALAMINÆ CUM HYDRARGYRO, P. C.) Calamine cerate lb. j; nitric oxide of mercury ℥j. *Proc.* Triturate the oxide until reduced to an impalpable powder, then add the cerate and thoroughly blend them together.

CERATE, CALOMEL. *Prep.* Simple cerate ʒvij; calomel ʒj; mix.

CERATE, CALOMEL, (COMPOUND.) Calamine cerate ℥ij; calomel ℥j; mix.

CERATE, CINCHONA. (Paris Codex.) Equal parts of extract of cinchona and simple cerate, mixed together.

CERATE, COMPOUND LEAD. *Syn.* GOULARD'S CERATE. CERATUM PLUMBI COMPOSITUM, (P. L.) *Prep.* Solution of diacetate of lead f℥iij; wax ℥iv; olive oil ½ pint; camphor ʒss. *Proc* Add 8 oz of the oil to the melted wax, and as soon as it begins to cool, add the solution of lead, and continue the stirring until cold; then add the camphor dissolved in the remaining portion of the oil.

Use A cooling cerate for burns, excoriations, &c

CERATE COMPOUND MERCURIAL. *Syn.* CERATUM HYDRARGYRI COMPOSITUM, (P. L.) *Prep.* Mercurial ointment and soap cerate, of each ℥iv; powdered camphor ℥j; mix.

Use. As a stimulant application to indolent tumors, and as a resolvent in enlarged joints, &c.

CERATE, COPPER. *Syn.* CERATUM CUPRI. *Prep.* Liquor of ammoniated copper 1 part; simple cerate 8 parts. *Proc.* Soften the cerate by heat, then add the cupreous solution, and stir until cold. (Swediaur.)

CERATE, COSMETIC. *Syn.* POMMADE EN CREME. *Prep.* Oil of almonds 5 oz.; white wax and spermaceti, of each ½ oz.; melt, add rose water 3 oz., and tincture of balsam of Mecca ½ oz.; stir until cold.

CERATE, HEMLOCK. (CERATUM CONII, St. B. H.) Hemlock ointment 12 oz.; spermaceti 2 oz.; white wax 3 oz.; melt the last two, then add them to the first, softened by a gentle heat. Used for inveterate cancerous, scrofulous, and other sores.

CERATE, HONEY (CERATUM MELLIS, P. C.) Lead plaster and beeswax, of each 4 oz.; olive oil 6 oz.; melt and add honey 5 oz.

CERATE, KIRKLAND'S NEUTRAL. *Prep.* Lead plaster ℥viij; olive oil and prepared chalk, of each ℥iv; mix with heat and add sugar of lead ʒiij, dissolved in distilled vinegar f℥iv. Stir until cold. *Use.* As a cooling dressing for indolent ulcers.

CERATE, MARSHALL'S. *Prep.* Palm oil and calomel, of each 2 oz.; sugar of lead 1 oz.; ointment of nitrate of mercury 4 oz.; mix thoroughly by rubbing them together in a Wedgewood mortar.

CERATE, MERCURIAL. (CERATUM MERCURIALE, P. L. 1746.) Strong mercurial ointment and yellow wax, of each 6 oz.; lard 3 oz. Melt the wax and lard together, then stir in the ointment.

CERATE OF ACETATE OF LEAD. (CERATUM PLUMBI ACETATIS, P. L.) Acetate of lead in fine powder ʒij; wax ℥ij; olive oil f℥viij; melt the wax in 7 oz. of the oil; then add the acetate of lead, separately rubbed down with the remaining oil; stir until cold.

Use. As a cooling cerate to burns, excoriations and inflamed sores.

CERATE OF ARSENIC. (CERATUM ARSENICI, P. U. S.) White arsenic in fine powder ℈j; simple cerate ℥j; mix.

CERATE OF NITRATE OF MERCURY. (CERATUM HYDRARGYRI NITRATIS, St. B. H.) *Prep.* Ointment of nitrate of mercury and simple cerate, equal parts; mix.

CERATE, OPIUM. (CERATUM OPII, DR. LAGNEAU.) *Prep.* Opium in fine powder ʒss; yelk of 1 egg; mix, then rub it up with simple cerate ℥ij.

CERATE, QUININE. (CERATUM QUINIÆ, F. H.) Sulphate of quinine 1 part; simple cerate 10 parts; mix well.

CERATE, RESIN. *Syn.* YELLOW BASILICON. BASILICON CERATE. CERATUM CITRINUM, (P. L. 1745.) C. RESINÆ FLAVÆ, (P. L. 1788.) CERATUM RESINÆ, (P. L. 1809, 1824, and 1836.) *Prep.* Yellow resin and wax, of each lb. j; melt; then add olive oil f℥xvj. Stir until cold.

Remarks. This cerate is a mild stimulant, de-

tergent, and digestive application; and is employed to dress foul and indolent ulcers.

The above is the form of the Lond. Ph., but the basilicon of the shops is seldom, if ever, made in this manner. The following forms are those commonly used on the large scale, but the product is inferior to the P. L.

II. Yellow resin 10 lbs.; beeswax 2 lbs.; linseed oil 7 lbs.; melt together and stir until cold.

III. As last, but use nut oil for linseed oil.

IV. Nut oil 1 gall.; beeswax 5 lbs.; yellow resin 14 lbs.

V. Lard (common) and linseed oil, of each 3 lbs.; yellow resin 9 lbs.; mix as before.

CERATE, ROSE. *Syn.* Lip Salve. (Ceratum Rosatum, P. Cod.) Oil of almonds 1 lb.; white wax ½ lb.; alkanet root 1 oz.; melt and digest until sufficiently colored, strain, and when cooled a little, add otto of roses (24 drops) to perfume.

CERATE, SAVINE. (Ceratum Sabinæ, P. L.) *Prep.* Lard lbs. ij; savine leaves lb. j; wax ℥viij. *Proc.* Melt the wax and lard, and boil the leaves in the mixture, then strain through a linen cloth.

Remarks. The preparation of this cerate requires caution, as the active principle of the savine being volatile, is injured by long boiling or too high a temperature. The leaves are usually boiled until they are crisp, but as this takes some time, the essential oil, and consequently the odor, is nearly all dissipated. A better plan is to express the juice from the leaves, and to add it to the wax and oil melted together, and just beginning to cool. As usually met with, this ointment has a deep green color, and the odor of the fresh plant, but neither of these is derived from the leaves, in the common process of making it. The first is caused by the addition of verdigris, and the latter by adding a little of the essential oil of savine to the compound when nearly cold. The cerate prepared according to the form of either of the British Colleges, has but a very pale green color, and that rapidly changes unless it be well covered up from the air. A greater quantity of color is got from the leaves by long digestion in the fat and wax in earthen vessels, at a moderate heat, than by hastily boiling. In this way a lively green is sometimes produced, but it rapidly changes.

The following forms are those that have been adopted by many druggists for the manufacture of this cerate.

II. Lard and suet, of each 6 lbs.; yellow wax 2 lbs.; melt them together in an earthen vessel; then add 2 oz. of distilled verdigris, previously rubbed down smooth in a mortar, with an equal weight of sweet oil; strain while hot into a large earthen pot, and when cooled a little, add 1 oz. of oil of savine; stir till cold.

III. Savine leaves 4 lbs.; yellow wax 2 lbs.; lard 8 lbs.; boil until the leaves become crisp; then strain, and add, of lively-colored green ointment 5 lbs.; and when cooled a little, 3 drs. of oil of savine. Stir briskly until cold. *Prod.* 13½ lbs.

The practice of coloring this cerate with verdigris, which is next to universal, cannot be too severely censured, as its therapeutic action is thereby altered. The copper may be detected by burning down a little in a platinum or Hessian crucible, washing out the ashes with a little dilute acid, placing the liquor in a glass tube, and pouring thereon liquid ammonia. When a blue color, ammoniureted copper will be produced, if copper be present.

Use. To keep blisters open.

CERATE, SOAP. (Ceratum Saponis, P. L.) *Prep.* Boil litharge ℥xv in distilled vinegar 1 gallon until dissolved, stirring continually; then add of Castile soap ℥x; boil again until the moisture be entirely evaporated: then add gradually, wax ℥xiiss, and olive oil 1 pint, previously melted together.

Remarks. Unless the above instructions be exactly followed in every particular, the process will miscarry. When this is the case, it will be found that the cerate on cooling will separate into two portions, and be full of hard gritty particles. To prevent this, care should be taken to use soap of the best quality. When once this mishap occurs, no boiling or stirring in the world will remove it. The only remedy is the addition of a little more soap, previously melted with some water, and again evaporating to a proper consistence. A small quantity of liquor of potassa will also have the same effect.

The color and consistence of this cerate wholly depend upon the length of time it is kept heated after the addition of the oil and wax. As evaporation proceeds, so do the color and consistence increase. Its usual color is that of a lively pale chocolate-brown, but occasionally it is much paler. This arises from its containing moisture, which, by stirring, reduces the color. The following form may be used on the large scale.

II. Distilled vinegar 6 galls.; litharge 5 lbs.; soap 3½ lbs.; yellow wax 4½ lbs.; olive oil 6 pints. Mix as above. (Good nut or poppy oil may be used for olive oil.)

Uses. Soap cerate is used as a cool dressing for scrofulous swellings, &c. It may be spread on linen and applied like a plaster.

CERATE, SIMPLE. *Syn.* Oil and Beeswax. Simple Dressing. Cérat simple, (*Fr.*) Ceratum simplex, (P. L. 1824.) Ceratum, (P. L. 1809 and 1836.) *Prep.* Olive oil f℥iv; yellow wax ℥iv; mix by heat, and stir until cold.

Remarks. This is the ceratum of the "London Pharmacopœia." It is used as a simple emollient dressing for excoriations and sores. The ceratum simplex of the Scotch College is spermaceti cerate. Simple cerate is but little used, preference being given to the next preparation.

CERATE, SPERMACETI. *Syn.* White Lip Salve. Cerat de blanc de Baleine, (*Fr.*) Simple Cerate, (P. E.) Ceratum album, (P. L. 1745.) C. Spermatis Ceti, (P. L. 1788.) Ceratum Cetacei, (P. L. 1809, 1824, 1836.) *Prep.* Spermaceti ℥ij; white wax ℥viii; olive oil 1 pint. Melt together and stir assiduously until cold. *Use.* As a soft cooling dressing.

Remarks. As soon as the materials are melted, they should be moved from the fire, strained into a clean vessel, and stirred until cold. To facilitate the cooling, the vessel may be placed in cold water or a current of cold air. This will render the product both whiter and finer than when allowed to cool by itself. The operation of melting should be performed in a water bath. On the large scale

perchloride of carbon formed. *Props.* Solid; smells somewhat like camphor; it is twice as heavy as water, fusible, volatile; soluble in alcohol, ether, and oils, and slightly so in water; combustible.

II. (*Protochloride.*) When the perchloride of carbon is passed through a glass or porcelain tube filled with fragments of glass or rock crystal heated to redness, chlorine is separated, and a vapor formed, which must be condensed by the application of cold. This is the protochloride of carbon. *Prop.* Liquid, limpid, and colorless; vaporizes at 165° F.

CHLORINE. *Syn.* Oxymuriatic Acid. An elementary substance discovered by Scheele in 1774, and named by him dephlogisticated marine acid. It was afterwards called by the French chemists *oxygenized* and *oxymuriatic* acid, on the supposition of its being a compound of muriatic acid and oxygen. In 1809, Gay Lussac and Thernard suggested that it might be regarded as a simple substance; but it was reserved for Sir H. Davy to prove the truth of this suggestion. After some researches, in which every method of decomposing it was tried that genius and experience could suggest, he declared it to be a simple body, and gave it its present name, (from χλωρὸς, *green*,) on account of its color.

Prep. I. Mix together in a glass flask or retort strong muriatic acid with half of its weight of finely-powdered peroxide of manganese. Chlorine gas is immediately evolved even in the cold, but much more rapidly on the application of a gentle heat. *Remarks.* This gas must be collected in clean dry bottles by displacement. The tube conducting the gas must reach to the bottom of the bottle, when the chlorine, being heavier than the air, will displace the latter, without mixing with it. The bottle is known to be full by the gas overflowing the mouth, which is easily perceived by its green color. The bottle must now be closed up with an accurately-fitting stopper, previously greased, and an empty one put in its place, which must be subsequently treated in like manner. To free the gas entirely from muriatic acid, it may be passed through water; and to render it dry, it may be passed over dry chloride of calcium. Chlorine gas may also be collected over a saturated solution of common salt in the pneumatic trough.

II. Pour common muriatic acid, diluted with an equal weight of water, upon half its weight of chloride of lime, and proceed as before.

III. Pour sulphuric acid, diluted with water upon a mixture of common salt and binoxide of manganese previously placed in a retort. The proportions ordered by different authorities vary; the following are the principal:

Brand	4 water	5 acid .	3 oxide	8 salt.
Liebig	2 "	2 " .	1 "	3 "
Thernard . . .	4 "	4 " .	2 "	3 "
Graham . . .	as much dilute acid as contains	13 of oil vitriol	6 "	8 "

Remarks. The first or second process is the most convenient for small experiments in the laboratory, and the latter may be adopted where peroxide of manganese cannot be procured. The third is the cheapest method, and that employed on the large scale. Mr. Julius Seybel has lately taken out a patent for improvements in the manufacture of sulphate of soda and chlorine, which are formed by one operation. This is done by decomposing common salt by sulphuric acid, in closed vessels of lead, or lined with lead, having heat applied externally; and in employing the vapor of the muriatic acid thus formed to act on manganese immersed in water, such vapor being conducted below and permitted to escape upwards through the water and manganese.

Prop. Chlorine is a gaseous substance, possessing a yellowish green color, a pungent suffocating odor, and an astringent taste. Its most remarkable properties are, its power of destroying almost all vegetable and animal colors, and the putrid odor of decomposing organic matter; hence its value as a bleaching agent, and as a disinfectant and fumigant. Water absorbs twice its volume of this gas, and acquires a yellowish color. Under a pressure of about four atmospheres it condenses into a yellow transparent liquid. With the bases, chlorine forms an important series of compounds, called chlorides, chlorurets, or muriates, of which calomel and common salt may be taken as examples, the first being a chloride of mercury, and the second of sodium. The metallic chlorides are mostly solid at common temperatures, and all, save two, (mercury and silver,) soluble in water. They are fusible, and often crystalline. The chlorides of tin, antimony, arsenic, and mercury, are volatile and sublime unchanged. The chlorides are generally colorless, and resemble the salts in appearance. They are mostly decomposed by a strong heat. They are not decomposed by pure anhydrous sulphuric acid, but readily so by oil of vitriol. The metallic chlorides may generally be formed by the direct action of chlorine on the metals at common temperatures, and in many instances the union is accompanied by the evolution of light and heat. They may also be frequently formed by dissolving the oxides, carbonates, or hydrates of the bases, in muriatic acid, and crystallizing, or applying heat, until all the water is expelled. Chlorine has such a strong attraction for the metals that it displaces oxygen in nearly all cases at a red heat.

Tests. This gas is readily distinguished from other gases by its color, odor, and bleaching properties. It forms a white curdy precipitate with nitrate of silver, (chloride of silver,) which is insoluble in nitric acid, but readily so in liquid ammonia, and is blackened by light. Its aqueous solution dissolves gold leaf, and instantly blackens a piece of silver plunged into it. It rapidly destroys the color of iodide of starch, solution of indigo, litmus, and turmeric. The soluble chlorides may be readily detected by acidulating their solutions with nitric acid, and then adding a solution of nitrate of silver, when chloride of silver will be precipitated, and may be recognised in the way just mentioned. The insoluble chlorides may be tested by digesting them in a little liquor of potassa, when a solution of chloride of potassium will be formed, which may be treated as a liquid chloride; or the chloride may be dissolved in nitric acid, and tested with nitrate of silver as before. A simple method of detecting free chlorine is to hold a rod, dipped in

water of ammonia, over it, when white fumes of sal ammoniac will be formed; this, coupled with the property of bleaching colors, may, in most cases, be taken as evidence of the presence of this substance. (See CHLOROMETRY.)

Ant. When the fumes of chlorine are inhaled, it proves an irritative poison. The best antidotes are said to be ammoniacal gas or the vapors of warm water, of wine, or of ether. The writer of this article once suffered severely from getting a full inspiration of this gas, by the bursting of a large vessel employed in its manufacture, and which was full at the time. For a minute or two he was completely overcome; but, on being removed into the fresh air, he rapidly recovered, and, with the exception of a *violent* and *convulsive* cough, which lasted several hours, felt even better than he did before. The gas appeared to have acted both as a mental and bodily stimulant. Every known antidote was tried in this case, but without any apparent advantage. The effects gradually wore off, after the lapse of seven or eight hours.

CHLORINE, LIQUID. *Syn.* OXYMURIATIC ACID OXYMURIATIC WATER. SOLUTION OF CHLORINE. CHLORINE WATER. DEPHLOGISTICATED SPIRIT OF SALT. *Prep.* I. (*Aqua Chlorinii*, P. D.) Mix 87 parts of sulphuric acid with 124 of water, and pour it upon 100 parts of dried muriate of soda and 30 parts of oxide of manganese, previously mixed together and placed in a retort. Conduct the gas evolved into 200 parts of distilled water.

II. (*Aqua Chlorinei*, P. E.) Muriate of soda 60 grs.; red oxide of lead 350 grs.; triturate together, and put them into f℥ viij of distilled water contained in a stoppered bottle; then add 2 fluid drachms of sulphuric acid, put in the stopper, and agitate occasionally until the oxide of lead turns white. The clear liquid (after subsidence) is to be poured off into another stoppered bottle.

III. Pass chlorine gas, procured by any of the methods mentioned under Chlorine, into water, until it will absorb no more.

CHLORITES. Salts formed of the chlorous acid with the bases. The alkaline chlorites may be formed by passing a current of chlorous acid gas into a solution of the pure alkalis. They are soluble and remarkable for their bleaching and oxidizing properties.

CHLORITES, (HYPO-.) These are formed by the action of chlorine gas on the salifiable bases. Chloride of lime, soda, and potash are said by some to be hypochlorites, but this is undecided; in fact, the very existence of the hypochlorites has been denied.

CHLORO-CARBONIC ACID. *Syn.* PHOSGENE. CHLORO-CARBONOUS ACID. *Prep.* Expose equal volumes of carbonic oxide and dry chlorine to the rays of the sun, or diffused daylight. In the first case combination ensues in a few minutes, in the second after a few hours. *Prep.* A colorless gas, having a disagreeable odor; easily decomposed, especially by water.

CHLOROMETER. *Syn.* CHLORIMETER. An instrument for testing the strength of chlorides.

CHLOROMETRY. *Syn.* CHLORIMETRY. CHLOROMETRIE, (*Fr.*) The process or operation of testing the decoloring power of the compounds of chlorine. It is principally applied to those met with in commerce,—the chlorides of lime, potash, and soda. Among the numerous tests proposed for this purpose, the following appear to be those most worthy of notice.

I. (*Dalton's test.*) Weigh exactly 78 grs. of pure proto-sulphate of iron, previously dried by strong pressure between the folds of cloth, and dissolve it in 2 oz. of distilled water, to which add a few drops of muriatic or sulphuric acid. Next weigh out exactly 50 grs. of the chloride of lime, well mix it in a mortar with 2 oz. of tepid water, and pour the mixture into a graduated tube or alkalimeter. Then fill the measure up to 0 with the washings of the mortar. The whole should be now well mixed, by placing the thumb over the orifice and shaking it. The solution of chloride of lime is next to be gradually and cautiously added to the solution of sulphate of iron, until the latter be completely peroxidized, which may be known when it ceases to be affected by the red prussiate of potash. The latter test is applied by putting a drop of its solution upon a white plate, and touching it with the point of a glass stirrer or rod, dipped in the liquor under examination. As soon as the test indicates that enough of the solution of the chloride has been added, the number of measures poured from the alkalimeter must be carefully observed, from whence the richness of the sample may be estimated, as follows:—As 100 of the alkalimeter divisions contain exactly 50 grs. of the chloride, each measure will contain half a grain, and, consequently, any number of measures consumed, will represent half that number of grains of the chloride under examination; and the weight of the chloride thus used will have contained 10 grs. of chlorine—the constant quantity of that substance required to peroxide the given solution of sulphate of iron. Thus;—If 80 measures of the liquor in the alkalimeter be consumed, this quantity will have contained 40 grs. of the chloride and 10 grains of chlorine. By dividing 1000 by this number, the per centage of chlorine will be obtained, thus:

$$\frac{1000}{40}=25\%.$$

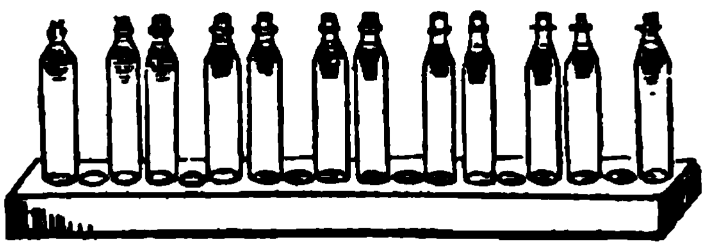
The above method admits of much greater accuracy, if the chloride of lime be dissolved in tepid water, placed in a Schuster's alkalimeter, previously weighed, and the solution made up to exactly 1000 grs. when cold. The quantity consumed may here be ascertained with great exactness. Every grain of the solution will be only equal to $\frac{1}{20}$ of a grain of the chloride. The quantity of the solution consumed is determined by weighing the alkalimeter before and after the operation. The difference is the quantity that has been used.

A modification of this plan has been suggested by Mr. Crum. He proposes to make the solution of the sulphate of iron in a stoppered bottle, and to add the chloride in the state of powder from a weighed quantity.

II. (*Crum's process.*) Mix equal weights of water and muriatic acid, and dissolve therein cast-iron borings until saturated. To ensure perfect saturation a large excess of iron is employed, and the liquid kept at the heat of boiling water for some time. One measure of the solution, marking 40° on Twaddle's scale, (sp. gr. 1·200,) is mixed with an equal quantity of acetic acid, (sp. gr. 1·048.)

This forms the proof solution, which, if mixed with 6 or 8 parts of water, is quite colorless, but chloride of lime occasions the production of peracetate of iron, which gives it a red color.

The above proof-solution is then poured into 12 two-oz. vials, of exactly equal diameters, to the amount of $\frac{1}{6}$ of their capacity; these are filled up with bleaching liquid of various strengths; the first at $\frac{1}{12}$ of a degree of Twaddle, the second $\frac{2}{12}$, and so on up to $\frac{12}{12}$ or 1°. They are then well corked up, and, after agitation, arranged side by side on a tray, furnished with holes to receive them, in the manner represented in the engraving. A se-



ries of test vials are thus formed, showing the various shades of color that the solutions of the given strengths are capable of producing. To ascertain the strength of an unknown sample of bleaching liquor, the proof solution of iron is put into a vial, exactly similar to the 12 previously used, and in precisely the same proportion, ($\frac{1}{6}$.) The vial is then filled up with the bleaching liquor, well shaken, and placed beside that one of the 12 already prepared which it most resembles in color. The number on that vial expresses the strength of the sample under examination, in $\frac{1}{12}$ths of a degree of Twaddle's hydrometer.

TABLE exhibiting the quantity of Bleaching Liquid, at 6° on Twaddle's scale, (sp. gr. 1·030,) required to be added to a weaker liquor, to raise it to the given strengths. Adapted from Mr. Crum's table by Mr. Cooley.

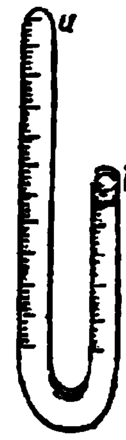
Strength of sample in $\frac{1}{12}$°.	Required Strength.	Proportions required. Given Sample.	Liquor at 6°.
		Parts.	Part.
Water.	$\frac{8}{12}$°	8	1
1	do.	9¼	1
2	do.	11	1
3	do.	13½	1
4	do.	17	1
5	do.	23	1
6	do.	35	1
7	do.	71	1
Water.	$\frac{6}{12}$°	11	1
1	do.	13½	1
2	do.	17	1
3	do.	23	1
4	do.	35	1
5	do.	71	1
Water.	$\frac{4}{12}$°	17	1
1	do.	23	1
2	do.	35	1
3	do.	71	1
Water.	$\frac{3}{12}$°	23	1
1	do.	35	1
2	do.	71	1

Remarks. The preceding method is admirably suited for weak solutions, such as are employed for bleaching textile fabrics, and is well adapted (from its simplicity) to the purposes of practical men. It is employed in many of the Scotch bleaching houses.

According to Mr. Crum, the range of strength within which cotton is safe, is very limited. A solution at 1° of Twaddle's scale, (sp. gr. 1·005,) is not more than safe, while one at ½° is scarcely sufficiently strong for the first operation on stout cloth, unless it be packed more loosely than usual. (Trans. Glasgow Phil. Soc.)

III. (*Ure's test.*) This consists in adding water of ammonia of a known strength, tinged with litmus, to a solution of a given weight of the chloride, until the whole of the chlorine be neutralized, which is known by the color ceasing to be destroyed. From the quantity of ammonia consumed, the strength is estimated. During the above process azote is evolved, and the estimation of the volume thus liberated has been proposed as another easy method of chlorimetry by Dr. Ure.

This gentleman recommends the two substances to be mixed in an inverted and graduated syphon tube over mercury. (See Engraving.) "The shut end *a* and the open end *b*, are both graduated to one scale; for example, to $\frac{1}{100}$ of an inch, or to grain or 10 grain measures. The tube is to be filled with mercury, and then 10 measures of it are to be displaced at the open end, by inserting a wooden plug. This space being filled with a solution of a given weight of chloride of lime, is to be turned up into the shut end, by covering the open end with the finger and inverting the tube; a few drops of water may be sent through to wash the mercury. The ammonia being now let up will cause a reaction, and evolve a quantity of azote, equivalent to the chlorine present. The action may be accelerated by holding the sealed end of the tube over the flame of a spirit-lamp. The mercury is protected from the chlorine by the ammonia; and should any notion be entertained of such an action, the ammonia may be let up first. I have made innumerable researches over mercury, with a detached apparatus of this kind, which combines precision with rapidity of result." (Ure's Dict. Arts.)



IV. (*Process of M. Gay Lussac.*) One part of the best indigo is dissolved in 9 parts of strong sulphuric acid, by the aid of a gentle heat. This solution is then mixed with distilled water, in such proportion, that 1 volume of chlorine gas shall exactly decolor 10 volumes of this solution. Each measure so decolored is called a degree, and each degree is divided into fifths. 5 grains of the best chloride of lime, dissolved in 500 grain measures of water, will possess the above power, and indicate 10° or proof, and will decolor 10 times its volume of the indigo solution. The objections to this method of chlorimetry are, that the indigo solution alters by keeping, and that it is not adapted for testing strong solutions of chloride of lime. "I have tried the indigo test in many ways, but never could confide in it." (Ure.)

CHLORO-NITROUS GAS. A gaseous compound, discovered by E. Davy. It is obtained

by treating fused chloride of sodium, potassium, or calcium, in powder, with as much strong nitric acid as is sufficient to wet it, when this gas is evolved. *Prop.* It has an orange color, smells like chlorine, and bleaches. Soluble in water.

CHLOROPHYLL. *Syn.* CHLOROPHILE. CHLOROPHYLE. The green coloring matter contained in the leaves, stalks, unripe fruit, and juices of most plants. It is extracted by ether, and purified by successive solutions in alcohol and muriatic acid; from the last it is precipitated pure by water.

Prop. A dark green mass, producing a grass-green powder. It is soluble in ether, alcohol, acids, alkalis, and oils. If an earthy or metallic salt be mixed with the alcoholic solution, and an alkaline carbonate be added, the earth or oxide is thrown down in combination with this coloring matter, forming a green lake, possessing considerable permanency. Pelletier and Caventou, who first discovered chlorophyll, obtained it by simply pressing the leaves, washing in water, and afterwards treating it with alcohol.

CHLOROUS ACID. *Syn.* PEROXIDE OF CHLORINE. A compound of oxygen and chlorine. *Prep.* Chlorate of potassa in fine powder, made into a paste with strong sulphuric acid, is put into a retort and heated in a water-bath, hot but not boiling. A yellowish green gas is given off, which may either be collected in dry bottles, or passed into water, when it will form liquid chlorous acid.

Props., &c. Its aqueous solution undergoes gradual decomposition, yielding chlorine and chloric acid. It possesses powerful oxidizing and bleaching properties, and unites with the bases forming salts called chlorites. These are all soluble in water, and possess bleaching powers like the acid. They may be recognised by the evolution of chlorous acid gas when acted on by an acid.

CHOCOLATE. *Syn.* CHOCOLADA. CHOCOLAT, (*Fr.*) The roasted cacao nut made into a paste by triturating it in a heated mortar, with sugar and aromatics, and cast in tin moulds, in which it concretes into cakes on cooling. The term is derived from two Indian words, *choco*, sound, and *atte*, water; because of the noise made in its preparation. (Dr. Alston.)

Qual. Chocolate is nutritive and wholesome, if taken in moderation, but is sometimes apt to disagree with weak stomachs, especially those that are easily affected by oily substances or vegetable food. The quantity of aromatics mixed with the richer varieties, improve the flavor, but render them more stimulant and prone to produce nervous symptoms, and complaints of the head.

Prep. The nuts are first roasted, (on the small scale this may be done in a frying-pan,) and after being cleared from the husks, reduced to coarse powder; they are then beaten in an iron mortar, the bottom of which is heated, until they are reduced to a paste, which is effected by the action of the heat on the oil or butter they contain. This paste or semi-fluid mass is then poured out into moulds, and left until cold, when it forms *cake chocolate*, or *chocolate paste;* or it may be reduced to coarse powder, by grinding, when it is known under the name of *chocolate powder*.

Remarks. Chocolate, prepared as above, without the addition of aromatics, is known in the trade as *plain chocolate*. The Spaniards flavor it with vanilla, cloves, and cinnamon, and frequently scent it with musk and ambergris. In general, they add too large a quantity of the last four articles. The Parisians, on the contrary, use but little flavoring, and that principally vanilla. They employ the best caracca nuts, and add a considerable quantity of refined sugar.

The mass of the common chocolate sold in England, is prepared from the cake left after the expression of the oil, and this is frequently mixed with the roasted seeds of ground peas, and maize or potato flour, to which a sufficient quantity of inferior brown sugar, or treacle and mutton suet is added, to make it adhere together. In this way is made the article commonly marked in the shops at 8*d*., 9*d*., and 10*d*. the pound. I know a person who lately bought a large quantity at 5*d*., whereas good nuts, in their unprepared state, cost at wholesale more than double the money.

To excel in the manufacture of chocolate requires some little experience. The roasting of the nuts must be done with great care, and the process stopped as soon as the aroma is well developed. They should then be turned out, cooled, and fanned from the husks. On the large scale, chocolate is made in mills, worked by steam power, and the machinery employed in the grinding, admirably fulfils its duty.

The South American beans are esteemed the best for making chocolate. Like wine, it improves by age, if kept in a dry but not too warm a place.

CHOCOLATE CREAM. *Prep.* Chocolate scraped fine 1 oz.; thick cream 1 quart; sugar (best) 6 oz.; heat it nearly to boiling, then remove it from the fire, and mill it well. When cold, add the whites of 8 or 10 eggs; whisk rapidly, and take up the froth on a sieve; serve the cream in glasses, and pile up the froth on the top of them.

CHOCOLATE DROPS. Reduce 1 oz. of chocolate to fine powder by scraping, and add it to 1 lb. of finely-powdered sugar; moisten the paste with clear water, and heat it over the fire until it runs smooth, and will not spread too much when dropped out; then drop it regularly on a smooth plate. Avoid heating it a second time.

CHOCOLATE FOR ICING. *Syn.* SORBET AU CHOCOLAT. *Prep.* Rub 2 oz. of chocolate to a paste with 2 tablespoonfuls of hot milk, then add cream for icing 1 quart. Ice as wanted for use.

CHOCOLATE FOR THE TABLE. *Prep.* Put the milk and water on to boil; then scrape the chocolate fine, from one to two squares to a pint, to suit the stomach: when the milk and water boils, take it off the fire, throw in the chocolate, mill it well, and serve it up with the froth, which process will not take five minutes. The sugar may either be put in with the scraped chocolate, or added afterwards.

It should never be made before it is wanted; because heating again injures the flavor, destroys the froth, and separates the body of the chocolate; the oil of the nut being observed, after a few minutes' boiling, or even standing long by the fire, to rise to the top, which is the only cause why chocolate can offend the most delicate stomach.

CHOCOLATE, FRENCH. *Prep.* Finest ca-

cao nuts 3 lbs.; best refined sugar 1 lb.; beans of vanilla 2 in number; grind together, as before described.

CHOCOLATE MILK. *Prep.* Dissolve 1 oz. of chocolate in 1 pint of new milk

CHOCOLATE POWDER. Cake chocolate scraped or ground. Usually sold in tin canisters.

CHOCOLATE, SPANISH. *Prep.* I. Caracca nuts 11 lbs.; sugar (white) 3 lbs.; vanilla 1 oz.; cinnamon (cassia) ¼ oz.; cloves ½ dr.; as above.

II. Caracca nuts 10 lbs.; sweet almonds 1 lb.; sugar 3 lbs.; vanilla 3 oz.; as above.

III. Caracca nuts 8 lbs.; island cacao 2 lbs.; white sugar 10 lbs.; aromatics as above.

IV. Island cacao 7 lbs.; farina to absorb the oil; inferior.

CHOCOLATE, VANILLA. *Syn.* Chocolat a la Vanilla. Caracca nuts 7 lbs.; Mexican vanilla 1 oz.; cinnamon ½ oz.; cloves 3 in number; as before.

II. Best chocolate paste 21 lbs.; vanilla 4 oz.; cinnamon 2 oz.; cloves ½ dr.; musk 10 grs.; as before.

CHOLERA. *Syn.* Cholera Morbus. English Cholera. (From χολη, *bile*, ρέω, *I flow*. Celsus.) A disease characterized by bilious vomiting and purging, accompanied by great pain and debility. It most frequently occurs towards the end of the summer and the beginning of autumn, and appears to be produced by sudden changes of temperature, checked perspiration, and the excessive use of indigestible fruit, &c. It is usually accompanied by fever, thirst, and severe abdominal pains, and *sometimes* by cold sweats, extreme debility, feeble pulse, &c., under which the patient sinks in 24 hours.

Treat. In most cases this complaint is not dangerous, and yields to proper treatment in a few days. As soon after the commencement of the attack as possible, some mild aperient, as castor oil, should be administered, and its action accelerated by drinking copiously of diluents, as barley-water, toast and water, water gruel, &c. Opiates may be employed, both topically and by the mouth. A teaspoonful of laudanum rubbed over the region of the stomach and bowels, is a simple method, and will generally allay the pain. 15 or 20 drops of laudanum, mixed with a tablespoonful of good brandy, may also be taken every hour, if the pain be severe. Should the stomach reject it, or the vomiting be apparently increased by drinking copiously, the same treatment should be persevered in. When the violence of the symptoms has abated, tonics and bitters, as gentian, calomba, orange-peel, &c., may be had recourse to.

CHROMATE. A saline compound, formed by the union of the chromic acid with a base. The chromates are characterized by their yellow or red color, the latter predominating when the acid is in excess.

Prep. The insoluble salts of chromic acid, as those of baryta, zinc, lead, mercury, silver, &c., may be made by mixing a soluble salt of those bases, with neutral chromate of potassa. The first three are red, the fourth orange, and the fifth deep red or purple.

Tests. 1. On boiling a chromate in hydrochloric acid, mixed with alcohol, chromic acid is first set free, and then decomposed, forming a green solution of chloride of chromium. 2. With acetate of lead, the chromates give a yellow precipitate; 3, with nitrate of silver, a reddish violet; 4, with nitrate of mercury, a red one.

CHROMATE OF POTASH. *Syn.* Salt of Chrome. Neutral Chromate of Potassa. On the large scale this salt is prepared from chrome ore, a natural octohedral chromate of iron, found in various parts of Europe and America.

Prep. I. The ore, freed as much as possible from its gangue, is ground to powder in a mill, and mixed with ½ or ⅓ of its weight of bruised nitre, and in this state exposed to a powerful heat for several hours, on the hearth of a reverberatory furnace, during which time it is frequently stirred up with iron rods. The calcined matter is next raked out and lixiviated with water. A beautiful yellow-colored solution results, which is evaporated briskly over a naked fire, when the chromate of potash falls down under the form of a granular yellow salt, which is removed from time to time with a ladle, and thrown into a wooden vessel, furnished with a bottom full of holes, called the draining box, where it is left to drain and dry. In this state it forms the commercial chromate of potash. By a second solution and crystallization, it may be obtained in larger and more regular crystals.

Remarks. As the object to be aimed at in conducting this process, is to procure a neutral chromate of potassa, it is evident that the quantity of chrome oxide in the ore should be first ascertained, so that the proper quantity of nitre may be added. In every case, the proportion of nitre or alkali should be *slightly* less than what is absolutely required to saturate the ore, as the production of a neutral salt is thereby ensured; and should not the whole of the chrome oxide be decomposed by the first burning, it may easily be roasted a second time with fresh alkali, should the remaining quantity be thought worth saving. These remarks also apply to the following formulæ.

II. Chrome ore (containing 50% of protoxide of chrome) 2 parts; saltpetre 1 part; as last.

III. Chrome ore of 34%, 4 parts; potashes 2 parts; nitre 1 part; as above.

IV. Chrome ore of 34%, 10 parts; potashes 5 parts; peroxide of manganese 1 part; as last.

V. (*Process of Mr. Charles Watt, jun.*) "I have tried numerous experiments, with a view to the employment of cheaper salts than the nitrates in this branch of manufacture. I have found that the sulphates of potassa and soda may be entirely substituted for the nitrates of those bases, by the simultaneous employment of lime, which assists in the decomposition of the sulphate.

"The process is as follows:—The sulphate is to be ground, or otherwise intimately mixed with the pulverized ore, and the lime* is then added, which should also be intimately mixed with the mass. It is then to be subjected, for about 4 hours, to a strong red heat. The nature of the furnace to be employed for the purpose is not of any great im-

* "It is quite immaterial whether the lime be in a state of carbonate, or otherwise; but I think, generally speaking, it will be found quite as advantageous to employ that which has been burnt, as it will save trouble and expense in grinding."

portance, so long as carbonaceous matters from the fire are entirely excluded, and the required temperature is attainable. Unless strong heat is employed, no decomposition will take place; the temperature already employed in manufacturing this article from the nitrates, will be sufficient, and the furnaces used in every way suitable. The mass should be well raked about every half hour, to ensure the whole of it being sufficiently heated.

"Proceeding thus, the manufacturer may ascertain whether the process is complete by taking out a sample from the furnace, and treating it with a slight preponderance of dilute pure nitric acid, then adding chloride of barium; if, on this addition, much precipitate of sulphate is formed, the operation is not completed; but if, on the other hand, only a slight milkiness is produced, the 'batch' may be considered as finished.

"I have found, from numerous analyses, that different samples of the ore vary considerably in the quantity of oxide of chromium which they contain, and I therefore advise every manufacturer to analyze a fair average sample before he makes a purchase."

The following is the plan which Mr. Watt has adopted for this purpose:—

"Take a given weight of the ore, say 200 gr., previously reduced to a fine powder, and intimately mix it with twice its weight of the nitrate of potassa or soda,* adding a little slaked lime to prevent it from fluxing; place it in an iron crucible, and subject it to a strong red heat for about 3 or 4 hours; then treat the mass with water to dissolve out the chromate. The insoluble matter having been washed several times until the water has ceased to come off colored, the washings are to be added together and evaporated to concentrate the solution. This being done, it is to be treated with an excess of dilute sulphuric acid to liberate the chromic acid, and then treated with spirit of wine, by which the chromic acid will be reduced to the state of green oxide, which will remain in solution in the preponderance of sulphuric acid employed. A solution of caustic ammonia in excess is then to be added, which will precipitate the oxide of chromium; the mass is then boiled to evaporate the superabundance of ammonia.

"It must now be passed through a filter to collect the oxide, and a little fresh water poured on it to free it from any saline matter: then gently dry on the filter, when it may be entirely removed with ease, as the oxide, which was previously of a very bulky nature, contracts very considerably. It may then be subjected to a dull red heat in a silver, platinum, or porcelain crucible, and afterwards its weight ascertained, from which the per centage of oxide of chromium which the ore contains, and, consequently, the amount of sulphate required to convert it into a chromate, may be calculated." (Chemist, iv. 70.)

Prop., Uses, &c. The commercial chromate of potash has a bright yellow color, but in other respects, resembles coarse culinary salt. It is used in various processes in the arts,—in dyeing, bleaching, the manufacture of chromic acid, bichromate of potassa, and several other chromates.

* "It will be as well to use a nitrate in the analysis; the quantity being small, it will be of no consequence."

Pur. Chromate of potash is very commonly adulterated with sulphate and muriate of potash, it therefore becomes important to the manufacturer to be able to test its purity.

I. (*Test of M. Zuber.*) Add tartaric acid, dissolved in 50 parts of water, to a like solution of the sample. As soon as the decomposition is complete, and the color verges towards the green, the supernatant liquor should afford no precipitate with either the nitrate of silver or baryta, whence the absence of muriates and sulphates may be inferred. The proportions are, 8 parts of tartaric acid to 1 part of the chromate, both in solution. If saltpetre be the adulterating ingredient, the sample will deflagrate when thrown upon burning coals.

Mr. Watt says, "A short time ago, I was supplied with a sample which was nothing but sulphate of soda and chloride of sodium, colored with a strong solution of the chromate, and which caused a white precipitate in any of the soluble salts of lead. For the benefit of the purchaser, I subjoin the following method of examining the chromates of potassa and soda.

"First ascertain the quantity of moisture contained in the sample, by weighing out a certain portion, drying it on a sand-bath, and again weighing; the loss of weight will give the quantity of water: then dissolve it in distilled water, and add any soluble salt of lead until it ceases to give a precipitate. The mass is then to be boiled, and more distilled water added; the supernatant liquor is then to be poured off, and if the sample under examination contain any chloride of sodium, small shining crystalline needles of chloride of lead will form in the liquor as it cools. The remaining precipitate is then to be treated with strong nitric acid, which will decompose the chromate; by adding distilled water, the nitrate of lead, formed by the decomposition of the chromate of lead, will be dissolved, and the remaining sulphate of lead, if any, may be dried, and its amount ascertained, from which the quantity of sulphate in the chromate may be calculated.

"If it be required to ascertain the quantity of chloride, this may be done by redissolving the chloride of lead by means of heat, and operating on it by any of the soluble salts of silver." (Chemist, iii. 388.

CHROMATE OF POTASH, (BI- OR SUPER-.) *Prep.* Acidulate a concentrated solution of the neutral chromate with sulphuric, or, still better, the acetic acid. Then heat the liquid and allow it to cool slowly, when beautiful red crystals of bichromate of potash will be deposited. Its *Prop., Uses, and Tests* are the same as the neutral salt.

CHROMATE OF POTASH, SOLUTION OF. *Prep.* Dissolve neutral chromate of potash 1 oz., in distilled water 1 lb. *Use.* As a test liquor for metals, especially lead.

CHROMATE OF SODA. This salt may be prepared in the same way as chromate of potash, by employing a salt of soda instead of potassa in the preceding processes. It may also be made on the small scale for experiment, by neutralizing chromic acid with carbonate of soda.

Remarks. This salt has been proposed as a substitute for chromate of potassa, and has the advantage in cheapness. "Why nitrate of *potassa*

Remarks. 1 drachm of this decoction, mixed with 7 drachms of water, forms a similar preparation to the Decoctum Sarzæ of the Pharmacopœia, and is now very frequently substituted for it in dispensing. (See SARSAPARILLA.)

DECOCTION OF SARSAPARILLA, COMPOUND. *Syn.* LISBON DIET DRINK. COMPOUND DECOCTION OF SARSAPARILLA AND THE WOODS. DECOCTUM LUSITANICUM. DEC. SARSAPARILLÆ COMPOSITUM, (P. D.) DEC. SARZÆ COMP., (P. L.) *Prep.* Decoction of sarsaparilla (boiling) 4 pints; sassafras chips, guaiacum, (rasped,) liquorice root, (bruised,) of each ℥x; mezereon root ℥iij; boil for 15 minutes, and strain.

Dose, &c. 4 to 6 oz. 3 or 4 times a day, either along with or after a mercurial course, in chronic rheumatism, lepra, psoriasis, and several other skin diseases. It is alterative and diaphoretic; during its use the skin should be kept warm. See the preceding articles, and SARSAPARILLA, in its alphabetical order.

DECOCTION OF SARSAPARILLA, COMPOUND, (CONCENTRATED.) There is a very considerable trade done in this article, in consequence of the compound decoction of sarsaparilla being very commonly ordered in prescriptions, and taken in large doses. When mixed with 7 times its weight of water, it forms a similar preparation to the *Decoctum Sarzæ compositum*, P. L.; and is very generally substituted for it in dispensing. When *honestly* and *skilfully* prepared, it is really a most *convenient* and *valuable* article; it is, however, more *frequently* met with of an inferior quality, and as the difference is not readily distinguished by mere ocular examination, it would be better for the dispenser to avoid employing it, unless it be ordered. The following formula is that employed by one of the largest metropolitan drug-houses, which is proverbial for the superior quality of their decoction of sarsaparilla.

Prep. Red Jamaica sarsaparilla 96 lbs.; mezereon root 9 lbs.; liquorice root (bruised) 16 lbs. *Proc.* These are packed into a clean copper pan, and two or three boards with as many ½ cwt. iron weights placed thereon; water is now run in, to about 10 inches higher than the ingredients, and heat is applied until ebullition commences. The materials are now allowed to macerate without boiling for about 6 hours, when the weights and boards are removed, and the liquid is gently boiled for 1 hour, care being taken to add fresh water from time to time, so as to keep the whole well covered. The decoction is next run off, and set evaporating as quickly as possible; the ingredients are then washed with boiling water, by allowing it to descend from a species of shower-bath, after the manner of "sparging," described under "*Scotch ale.*" This is repeated until the water runs off nearly colorless. The whole of the liquid is now evaporated without delay, until reduced to 8¼ gallons, when, after cooling, 2 drachms of essential oil of sassafras, dissolved in 2 gallons of rectified spirit of wine, are added, and afterwards, 1 pint of essence of guaiacum. The liquid is then placed in a suitable sized barrel, set upon its head, fitted with a small cock, (*not* placed *too* near the bottom,) and allowed to repose for a week, by which time it becomes clear and brilliant.

Remarks. To conduct this process successfully, several large copper pans are required; one of which, to boil the ingredients in, must be capable of containing from 120 to 150 gallons at least, and the remainder sufficiently large to receive the liquors drawn off. The evaporation and decoction should also be conducted by steam-heat. A very excellent plan adopted by some houses is, to employ large wooden vats, and to apply the heat by means of pipes laid along the bottom, and supplied with high-pressure steam. This method is less expensive than the use of double steam pans, as above. When essence of guaiacum is not used, 24 lbs. of guaiacum shavings, from which the dust has been sifted, are boiled with the other ingredients instead. (See SARSAPARILLA.)

DECOCTION OF SENEGA ROOT. *Syn.* DEC. OF AMERICAN SNAKEROOT. DEC. SENEGÆ, (P. L.) *Prep.* Seneka root ℥x; water 2 pints; boil to one-half, and strain.

Dose. f℥iss to f℥iij, three or four times daily, in humoral asthma, chronic cough, dropsy, &c. It is stimulant, expectorant, and diuretic, and in large doses, emetic and cathartic. It is the antidote employed by the Senegaro Indians against the bite of the rattlesnake. (Dr. Tennant.)

DECOCTION OF SQUILLS, COMPOUND. *Syn.* DEC. SCILLÆ COMP. *Prep.* (P. U. S.) Squills ℥iij; juniper berries ℥iv; snakeroot ℥iij; water lb. iv; boil to one half, strain, and add of sweet spirits of nitre f℥iv.

DECOCTION OF STARCH. *Syn.* MUCILAGO AMYLI, (P. L. 1788–1824.) DEC. AMYLI, (P. L. 1836.) *Prep.* Starch ℥iv; water 1 pint; mix gradually and boil for a short time. *Use.* As an enema in dysentery, diarrhœa, and excoriations of the rectum.

DECOCTION OF STEMLESS MILK VETCH. *Syn.* DEC. ASTRAGALI. *Prep.* (P. Cod.) Root of the astragalus escapus ℥x; water 3 pints; boil to 1 quart. *Dose.* The whole to be taken within the 24 hours. Alterative, &c.

DECOCTION, STRENGTHENING. *Syn.* TONIC DECOCTION. *Prep.* I. Peruvian bark, bruised, ℥ss; Virginian snakeroot ℥ij; water 1 pint; boil to one half, strain, and add spirits of cinnamon ℥iss; diluted sulphuric acid ℥iss. *Dose.* 2 oz. two or three times a day.

II. Decoction of bark ℥v; tincture of bark ℥vj; aromatic confection ℈j; sal volatile ℥j. *Dose.* 1 or 2 tablespoonfuls night and morning.

DECOCTION OF SUET. *Syn.* ARTIFICIAL GOAT'S MILK. DEC. SEVI. *Prep.* (Dr. Cummin.) Tie some chopped mutton suet in a piece of muslin, and simmer it for a short time in milk.

DECOCTION, SYDENHAM'S WHITE. *Syn.* HARTSHORN DRINK. MISTURA CORNU USTI. *Prep.* Prepared burnt hartshorn ℥ij; gum arabic ℥j; water 3 pints; boil to 1 quart and strain. Mucilaginous; demulcent.

DECOCTION OF TAMARINDS. *Syn.* DEC. TAMARINDORUM. *Prep.* Tamarinds ℥iss; water 1 pint; boil for 5 minutes and strain. A pleasant drink in fevers, asthma, chronic coughs, &c.

DECOCTION OF TAMARINDS AND SENNA. *Syn.* DEC. TAMARINDORUM CUM SENNA, (P. E. 1744.) Tamarinds ℥vj; cream of tartar ℥ij; water f℥xxiv; boil in a glazed earthen vessel until reduced to f℥xiv; then infuse therein for 12

hour until the process be completed, which may be known by the mass assuming a yellow color, instead of the grayish one it previously possessed. Care must be taken not to employ too much heat, as the product of this process (chromate of lime) is readily decomposed, and assumes a green color, in which case it is rendered useless. From the chromate of lime the acid is procured by the action of an equivalent proportion of sulphuric acid. This process has the great recommendation of cheapness, and Mr. Watt says that he has employed it in the factory of Messrs. Haws, for nearly two years, with *perfect success.*

Prop., Uses, &c. Pure chromic acid forms red crystals, and is soluble in water and alcohol. It is readily decomposed by the action of light and contact with organic matter. Hence it should be kept in stoppered glass bottles, and its solution filtered through asbestos. The ease with which it parts with a portion of its oxygen constitutes its value as a bleaching agent. It is largely employed in the arts, in calico-printing, bleaching of textile fabrics, tallow, oils, &c.

CHROMIUM, (from χρωμα, color.) A metal discovered by Vauquelin in 1797.

Prep. I. Mix dry chloride of chromium with oil, place the paste in a crucible lined with charcoal, lute on the cover, and expose it for an hour to an intense heat. (Vauquelin.)

II. Heat the compound of terchloride of chromium and ammonia to redness, and expose it to a current of dry ammoniacal gas. (Liebig.)

Remarks. The product of the first process has a whitish-yellow color, and a metallic lustre; that of the second is a black powder. Metallic chromium has not been applied to any use in the arts.

CHROMIUM, CHLORIDE OF. *Syn.* SESQUICHLORIDE OF CHROMIUM. *Prep.* I. Dissolve the hydrated oxide in muriatic acid, and evaporate to dryness.

II. Digest chromate of lead in muriatic acid mixed with a little alcohol, and throw down the excess of lead with sulphureted hydrogen.

III. Pass dry chlorine over a mixture of chrome oxide and charcoal heated to redness, in a porcelain tube. The chloride collects as a sublimate, of a peach or purple color.

Remarks. By the first process the product is a green powder, which, when heated to 400°, becomes purplish red, and then forms pure, dry chloride of chromium. This process should be performed in a tube filled with carbonic acid gas.

CHROMIUM, OXIDE OF. *Syn.* SESQUIOXIDE OF DITTO. *Prep.* To a solution of chromate of potash, add another of protonitrate of mercury as long as any precipitate falls down. This must be well washed in water, and heated to redness in an earthen crucible.

II. Expose bichromate of potash to a strong red heat, then wash out the potassa with water.

III. Expose bichromate of potash, mixed with half its weight of sulphur, as above.

Prep. A green powder, insoluble in water. Fused with borax or glass, it imparts a beautiful green color. The emerald owes its color to this oxide. With the acids it forms salts which also have a green color. These compounds may be made by adding equal parts of muriatic acid and alcohol to a boiling solution of chromate of potassa, in water, in small portions at a time, until the red tint disappears, and the liquid assumes a green color. Pure ammonia, in excess, should now be added, when a hydrated green oxide will subside, which, after being washed with water, may be dissolved in the acids. Oxide of chrome is much used in the manufacture of colored glasses and enamels, and in dyeing.

Remarks. The above appears to be the only oxide of chromium, in opposition to the assertion of Berzelius, that there is a protoxide and deutoxide.

CHRYSAMMIC ACID. *Prep.* Add 1 part of aloes to 8 of nitric acid of sp. gr. 1·37, and heat the mixture in an open vessel. When the first violent action is over, introduce the whole into a retort, and distil to two-thirds. Then add 4 parts more of nitric acid, and keep the mixture nearly at the boiling point for some days, or as long as gas is disengaged. Water should next be added, which will throw down impure chrysammic acid, while chrysolepic acid and oxalic acid will remain in solution. The precipitate must be well washed with water combined with potash, and purified by recrystallization. The crystals are next dissolved in water, and nitric acid added, when a golden yellow powder will be deposited, which is chrysammic acid.

Prop. Soluble in alcohol, ether, and hot acids; explodes by heat, and forms salts, called chrysammates, with the bases. The salt of potash, prepared as above, is a beautiful crystalline carmine red powder, and when slowly produced it forms beautiful small greenish golden crystals. The salts of soda and magnesia are similar. Ammonia forms, with chrysammic acid, a deep purple solution, which deposites dark green crystals. The other salts of this acid are all of great beauty, and mostly of various shades of red, and exhibit a golden lustre under the polishing steel.

CIDER. *Syn.* CYDER. POMATIUM. CIDRE, (*Fr.*) The fermented juice of the apple. Cider and perry were known to antiquity, and are mentioned by Pliny, who calls them the wine of apples and pears. Modern Europe is, however, indebted to the Moors of Biscay, who introduced its manufacture into Normandy, whence it spread into the other provinces of France, into England, Germany, Russia, and America. The best cider made at the present day is that of Normandy, Herefordshire, and New Jersey, (U. S.,) and, next, that of Devonshire and Somersetshire. The last is, however, very inferior. Cider is made in all the temperate climates of the world, where the heat is insufficient to produce the grape, and the cold not so great as to interfere with the growth of the apple.

The process of making cider varies in different parts of England, but in every case essentially consists of—the collection of the fruit; the expression and fermentation of the juice; and the storing and management of the fermented liquor.

The apples are crushed or ground in a mill, and the pulp placed in haircloth or coarse canvass bags, and subjected to powerful pressure; the liquor which runs off is put into casks, and freely exposed to the air in the shade, and allowed to ferment. This part of the process is carefully watched, and as soon as the sediment has subsided, the liquor is racked off into clean casks. Before winter the

casks are stored in a cellar, or other cool place, where the temperature is low and regular, and by the following spring the liquor is fit for use or bottling.

Remarks. Much of the excellence of cider depends upon the temperature at which the fermentation is conducted; but this is a point utterly overlooked by the manufacturers of this liquor. Instead of the apple-juice, as soon as expressed from the fruit, being placed in a cool situation, where the temperature should not exceed 50° of Fahr., it is frequently left exposed to the full heat of autumn. In this way much of the alcohol formed by the decomposition of the sugar is converted into vinegar, by the absorption of atmospheric oxygen, and thus the liquor acquires that peculiar and unwholesome acidity, known in the cider districts by the name of "*roughness.*" On the contrary, if the fermentation be conducted at a low temperature, nearly the whole of the sugar is converted into alcohol, and this remains in the liquor instead of undergoing the process of acetification. The acetous fermentation, or the conversion of alcohol into vinegar, proceeds most rapidly at a temperature of 95° Fahr., and at lower temperatures, the action becomes slower, until at 46° 50″ Fahr., no such change takes place. (Liebig.) It is therefore quite evident that if the saccharine juice of apples, or any other fruit, be made to undergo the *vinous* fermentation in a cool situation, less of the spirit resulting from the transformation of the sugar will be converted into acetic acid, and consequently more will be retained in an unaltered state in the liquor, and tend not only to improve its quality, but by its conservative and chemical action, to precipitate the nitrogenous substances, or exciters of future change. Independently of differences in the quality of the fruit, this is the principal cause of the superiority of the cider made by one person over another, living in the same district. The one has probably a cooler barn and cellar than the other to store his cider in. In practice it has been found that sour and rough-tasted apples produce the best cider. This arises because they contain less sugar and more malic acid, and the presence of the latter impedes the conversion of alcohol into vinegar. But cider made with such apples can never equal in quality that prepared *at a low temperature* from fruit *abounding in sugar.* In Devonshire the pressing and fermentation are conducted in situations where the temperature varies but little from the external air, and fluctuates with all its changes; the result is that Devonshire cider, of the best class, will rarely keep more than 5 or 6 years, and seldom improves after the second or third year, while the cider of Herefordshire and Worcestershire, where these operations are more carefully attended to, will keep for 20 or 30 years.

In the cider counties the culture of the apple engages especial attention. Dry rising ground, sheltered from the northerly and easterly winds, is best suited for an orchard. The fruit, after being gathered, is usually left for 14 or 15 days, in a barn or loft, to mellow or mature, during which time a considerable portion of the mucilage is decomposed, and alcohol and carbonic acid developed. The spoiled apples should then be separated from the sound ones, as they not only impart a bad flavor to the cider, but prevent its spontaneous clarification. Unripe apples should also be avoided, as they do not contain sufficient sugar to undergo the vinous fermentation, while they contribute to render the liquor rough and acidulous. Sour and rough-tasted apples are usually preferred by farmers for making cider, but fruit abounding in sugar would be preferable, provided the same skill were exercised in the manufacture of cider as in the process of brewing malt liquor.

As the juice of apples contains less sugar in proportion to the amount of acid and nitrogenized matter than that of grapes, the addition of some of this article would render it more suitable for the production of a vinous liquor. Good West India sugar is the best for this purpose. I have tasted cider made in this way, and that had been stored in fresh emptied rum puncheons, that had all the pungency and vinosity of foreign wine.

The best cider yields about 9 or 10% of real alcohol. Ordinary cider from 4 to 6%.

CIDER, DEVONSHIRE. The apples, after being plucked, are left in heaps in the orchard for some time, to complete their ripening, and render them more saccharine. They are then crushed between grooved cylinders, surmounted by a hopper, or in a circular trough, by two vertical edge-wheels of wood moved by a horse; after passing through which, they are received into large tubs or cives, and are then called pommage. They are afterwards laid on the vat in alternate layers of the pommage and clean straw, called reeds. They are then pressed, a little water being occasionally added. The juice passes through a hair sieve, or similar strainer, and is received in a large vessel, whence it is run into casks or open vats, where every thing held in mechanical suspension is deposited. The fermentation is often slow of being developed; though the juice be set in November or December, the working sometimes hardly commences till March. Till this time the cider is sweet; it now becomes pungent and vinous, and is ready to be racked for use. If the fermentation continue, it is usual to rack it again into a clean cask that has been well sulphured out, and to leave behind the head and sediment; or two or three cans of cider are put into a clean cask and a match of brimstone burned in it: it is then agitated, by which the fermentation of that quantity is completely stopped. The cask is then nearly filled, the fermentation of the whole is checked, and the cider becomes fine. If, on the first operation, the fermentation is not checked, the process of racking is repeated until it becomes so, and is continued from time to time till the cider is in a quiet state and fit for drinking.

A common practice in Devonshire is to add a stuff called "*stum,*" sold by the wine-coopers, or an article called "*anti-ferment,*" sold by the druggists, for the purpose of checking the fermentation, but a much better plan is to *rack*, as above described, into a well-sulphured cask, and to add 5 or 6 oz. of mustard-seed, and ½ oz. cloves, both well bruised; racking into a fresh-emptied spirit cask is also a good plan.

About six sacks, or twenty-four bushels of apples, are used for a hogshead of 63 gallons. If the weather be warm, it will be necessary to carry on the process in the shade, in the open air, and by every means to keep the juice as cool as possible

In nine months it will usually be in condition for bottling or drinking; if it continues thick use some isinglass finings, and if at any time it ferments and threatens acidity, the cure is to rack it, and leave the head and sediment behind.

CIDER, CHAMPAGNE. *Prep.* Good pale vinous cider 1 hogshead; proof spirit (pale) 3 gallons; honey or sugar 14 lbs.; mix, and let them remain together in a temperate situation for 1 month; then add orange-flower water 1 quart; and fine it down with skimmed milk ½ a gallon.

Remarks. This will be very pale; and a similar article, when bottled in champagne bottles, silvered, and labelled, has been often sold to the ignorant for champagne. It opens very brisk, if managed properly.

CIDER CHEESE. The residuum or cake of pommage or bruised apples, from which the juice has been expressed. It forms excellent food for pigs, and is very acceptable to them.

CIDER, FRENCH. After the fruit is mashed in a mill, between iron cylinders, it is allowed to remain in a large tun or tub for 14 or 15 hours, before pressing. The juice is placed in casks, which are kept quite full, and so placed upon gawntrees, or stillions, that small tubs may be put under them, to receive the matter that works over. At the end of 3 or 4 days, for *sweet cider*, and 9 or 10 days for *strong cider*, it is racked into sulphured casks, and then stored in a cool place.

CIDER, MANAGEMENT OF. Cider should be stored in a cool place, and should not be drunk before it becomes sufficiently mature. To improve the flavor of a hogshead of cider, 1½ gallons of good brandy or rum are frequently added, with 2 oz. of powdered catechu, (dissolved in water,) 7 lbs. of good moist sugar or honey, ½ oz. each of bitter almonds and cloves, and 4 oz. of mustard seed. These must be well rummaged in, and occasionally stirred up for a fortnight, after which it must be allowed to repose for 3 or 4 months, when it will usually be found as bright as wine. Should this not be the case, it must be fined with a pint of isinglass finings, or a dozen eggs, and in a fortnight more it will be fit for use. If the cider be preferred pale, omit the catechu, and instead of isinglass fine with a quart of skimmed milk. If wanted of a light reddish, or rose tint, use ½ oz. of cochineal, and omit the catechu.

Preparatory to bottling cider it should be examined, to see whether it be clear and sparkling. If not it should be clarified in a similar way to beer, and left for a fortnight. The night before it is intended to put it into bottles, the bung should be taken out of the cask, and left so until the next day, when it may be bottled, but not corked down until the day after, as, if this be done at once, many of the bottles will burst by keeping. The best corks, and champagne-bottles should be used, and it is usual to wire and cover the corks with tinfoil, after the manner of champagne. A few bottles may be kept in a warm place to ripen, or a small piece of lump sugar may be put into each bottle before corking, if the cider be wanted for immediate use, or for consumption during the cooler portion of the year, but for warm weather and for long keeping this is inadmissible. The *bottled stock* should be stored in a cool cellar, when the quality will be greatly improved by age. Cider for bottling should be of good quality, and at least 18 months old.

CIDER, MADE. An article under this name is made in Devonshire, for the supply of the London market, it having been found that the ordinary cider will not stand a voyage to the metropolis without some preparation. The finest quality of made cider is only ordinary cider racked into a clean cask, and well sulphured; but the mass of that which is sent to London, is mixed with water, treacle, and alum, and then fined down, after which it is racked into well-matched casks. The larger portion of the cider sold in London, professing to be Devonshire cider, would be rejected even by the farmers' servants in that county.

CIDER MOIL. *Syn.* WATER MOIL. A weak cider or liquor, prepared by adding water to the pressed cake, and fermenting. Very inferior.

CIDER, RAISIN. This is made in a similar way to raisin wine, but without employing sugar, and with only 2 lbs. of raisins to the gallon, or even more, of water. It is usually fit for bottling in 10 days, and in a week more is ready for use.

CIDER-SPIRIT. *Syn.* CIDER BRANDY. Obtained from cider by distillation. It is largely manufactured in America, where a very decent article may be purchased for about 50 cents per gallon, at proof. An illicit distillation of this spirit is frequently carried on by the farmers in the west of England.

CIGARS, MERCURIAL. M. Paul Bernard lately proposed to the Académie de la Médecine the use of cigars impregnated with a weak solution of bichloride of mercury, for persons afflicted with syphilitic affections of the throat and palate, as a mode of conveying mercurial fumigation. It has been proposed first to deprive the tobacco of its nicotin by frequent washings. (Lancet, May 13, 1843.)

CINCHONA BARK. There are three kinds of cinchona bark employed in medicine; the cortex cinchonæ lancifoliæ, (of the London and Dublin Pharmacopœias,) or the cortex cinchonæ condaminea, (of the Ed. Ph.,) commonly known in commerce as pale, crown, loxa, or quillbark; the cortex cinchonæ cordifoliæ, (Lond. and Dub.,) or the cortex cinchonæ flavæ, (Edin.,) commonly known as yellow or royal yellow bark; and the cortex cinchonæ oblongifoliæ, (Lond. and Dub.,) or red cinchona bark, (Edin.;) medically considered, they are all tonic and febrifuge, and may be given in powder, from 20 grs. to ℥ij, every two or four hours, so as to get down an ounce between each fit of intermittent fever; used also to stop the progress of gangrene; they are also given in infusion and decoction. Since the introduction of the cinchona alkaloids, the employment of bark in substance has considerably lessened.

Pur. The officinal species of cinchona bark are frequently imported mixed with other kinds, that contain less of the febrifuge principle. The most common adulteration is, however, the admixture of the same drug that has been exhausted of its active portions. This method consists in employing the bark, but slightly broken, (or generally whole, as imported,) for the manufacture of sulphate of quinine, cinchonine, and tincture, infusion, decoction, and extract of bark, after which it is carefully dried, without injury to its color, and

mixed up with fresh bark for sale, or is sent to the mill to be ground into powder. The greater amount of adulteration is generally practised on the powder, on account of the fraud being less easily detected when the drug is in the pulverulent state. Not only is the worst description of bark chosen for grinding, frequently largely admixed with exhausted bark, as just mentioned, but "the roots of bistort, calamus aromaticus, avens, water-avens, and tormentil; oak bark, that of several kinds of willow, horse-chesnut, ash, and the sloe bush; mahogany sawdust, the dried herbs of yellow loosestrife, bugle, water-horehound, and self-heal, are used either as substitutes or to reduce the price of the ground bark; as is also the root of Geum montanum. The barks of Pinknea pubescens, Unnona febrifuga, Swietenia febrifuga, Cedrela tuna, Magnolia glauca, M. acuminata, M. tripetala, Achras sapota, Rubus trivialis, and R. villosus, are also used as substitutes," (Gray;) and, in fact, any trash that will possibly produce a powder at all resembling that of bark, or that can be made so by grinding and the addition of coloring.

Tests. The simplest and only certain method of ascertaining the quality of cinchona bark, and of detecting fraudulent admixture, is by an assay for the alkaloid. (See QUINOMETRY.) The tannic acid which exists in every species of cinchona bark, may be recognised by its precipitating the sesquichloride of iron of a green color, gelatine of a whitish color, and a solution of tartar emetic of a *dirty* white.

CINCHONIA. *Syn.* CINCHONINE. CINCHONINA. CINCHONIUM. An alkaline principle extracted from pale cinchona bark, in the same way as quinine is from yellow cinchona bark.

Prep. I. Add ammonia to a dilute solution of sulphate of cinchonine, as long as any precipitate falls. Wash with cold water, dissolve in alcohol and crystallize.

II. A pound of bruised bark is boiled in about a gallon of water, to which 3 fluid drachms of sulphuric acid have been previously added. A similar decoction is repeated with about half the quantity of liquid, and so on till all the soluble matter is extracted. The decoctions are then mixed together, and strained; and powdered slaked lime is added, in a proportion somewhat greater than necessary to saturate the acid; the precipitate that ensues (a mixture of cinchonina and sulphate of lime) is collected, dried, and boiled for some minutes in strong alcohol, which is then decanted off while still hot, and fresh portions successively added for the repetition of the same operation, until it ceases to act on the residuum, which is then merely sulphate of lime. The different alcoholic solutions are then put into a retort or still, and considerably evaporated, during which, and especially on cooling, acicular crystals of cinchonina are deposited. When the whole is thus collected, the crystals, if yellow or discolored, must be again dissolved in boiling alcohol, and thus, by recrystallization, they will be obtained colorless. (Brande's Manual of Pharm.)

III. Boil Peruvian bark in alcohol until all the bitterness is extracted; distil to dryness, dissolve the extract in boiling water, rendered very sour, with muriatic acid; add calcined magnesia, boil for a few minutes till the liquor is clear; when cold, filter, wash the sediment left on the filter with cold water, dry it, boil alcohol upon it until all the bitterness is extracted; pour off the alcohol, and, as it cools, the cinchonine will crystallize. It may be purified by solution in a very weak acid, and the addition of an alkali.

Prop. and Uses. These are similar to quinine It is, however, rather less soluble in water than that alkaloid, as it requires 2500 parts of water, at 60°, for its solution. It forms salts with the acids, all of which may be made in the same manner as those of quinine. The neutral sulphate, bisulphate, disulphate, muriate, nitrate, iodide, iodate, &c. have been formed and examined.

Purity and Tests. (See QUININE.)

CINNAMMIC ACID. A substance discovered by Dumas and Peligot in oil of cinnamon. It crystallizes out of the oil when long exposed to the atmosphere.

Prep. Dissolve oil of balsam of Peru in potassa water, evaporate to dryness, dissolve the residuum in boiling water, and add an excess of muriatic acid. The cinnammic acid is deposited in crystals as the solution cools, and may be purified by re-solution and crystallization.

II. By cautious distillation of balsam of Tolu by a gentle heat it fuses, and a little water and volatile oil first comes over, followed by cinnammic acid, in the form of a heavy oil, which condenses on the cool parts of the neck of the retort, as a white crystalline mass. Towards the end of the process, some empyreumatic oil distils over. The acid must be purified by pressure between the folds of filtering paper and solution in boiling water. On cooling, minute colorless crystals of cinnammic acid will be deposited. Pure balsam of Tolu yields about ⅙ of its weight of this acid. (Mr. Heaver in the Ann. Chym.)

Prop. Colorless transparent scales, or prisms, scarcely soluble in water, but freely so in alcohol. Fuses at 240°; volatilizes unchanged at 555°. It forms salts with the bases, called cinnammates, which generally resemble the benzoates.

CINNAMEINE. *Syn.* OIL OF BALSAM OF PERU. *Prep.* Add an alcoholic solution of balsam of Peru, to a like solution of potassa. A compound of resin and potassa is precipitated, and cinnammate of potassa and cinnaméine are left in solution. On adding water, the latter separates and floats upon the surface.

II. Add 2 measures of balsam of Peru to 3 of liquor of potassa, (sp. gr. 1·300,) apply a gentle heat, when a yellowish brown oil will separate and float above a heavy black liquid, containing the potash. The former must be collected, and may be purified by cautious distillation.

Prep., &c. It dissolves in alcohol and ether, and by the action of alkalis is converted into cinnammic acid.

CINNAMON. From the high price of this drug, it has become a general practice to substitute cassia for it, which so exceedingly resembles it that most persons, unacquainted with the drug, regard them as the same. Cassia is, however, not only thicker and coarser than cinnamon, but its fracture is short and resinous, and its flavor is more biting and hot, while it lacks the peculiar sweetish taste of the latter spice. The thickness of cinna

men seldom exceeds that of good drawing paper. The same remarks are also applicable to the oil and powder. In pharmacy it is a general practice to employ cassia and its preparations whenever those of cinnamon are ordered. Both these drugs are wholesome aromatics. The principal consumers of genuine cinnamon are the chocolate-makers of France, Spain, Italy, and Mexico. The Germans, Turks, and Russians prefer chocolate flavored with cassia. "Some cinnamon, sent to Constantinople by mistake, proved unsaleable at any price, while cassia, worth about sixpence per pound, was in great request." (Pereira.)

CITRATES. Salts formed of the citric acid and the bases.

Prep. Those in general use may be all made by the addition of either the hydrate, oxide, or carbonate of the base, to a solution of the acid in water, until the latter be neutralized, when crystals may generally be obtained by evaporation.

Prop., &c. The citrates are mostly soluble, and when heated, froth, blacken, and are decomposed. When an anhydrous citrate is decomposed by an alcoholic solution of hydrochloric acid, the citric acid is principally transformed into hydrated aconitic acid.

Char. and Tests. The citrates are characterized by giving a white precipitate with acetate of lead, soluble in ammonia, and also a white precipitate with nitrate of silver, which, by the application of heat, froths up, deflagrates, and leaves an abundant ash, which, on increasing the heat, becomes pure silver.

Remarks. The principal citrates are *citrate of ammonia*, (soluble and crystallizable;) *citrate of potash*, (very soluble and deliquescent;) *citrate of soda*, (large crystals, soluble;) *citrate of baryta*, (beautiful shining silvery bushes, scarcely soluble;) *citrate of lime*, (see CITRIC ACID;) *magnesia*, *alumina*, and *protoxide of manganese*, each form 2 salts with citric acid, one soluble, the other insoluble; *citrate of protoxide of iron*, (scarcely soluble and crystallizable;) *percitrate of iron*, (soluble and brown;) *ammonio-citrate of iron*, (garnet colored, very soluble;) *citrate of zinc*, (scarcely soluble;) *citrate of lead*, (insoluble white powder;) *citrate of copper*, (green powder;) *citrate of silver*, (brilliant white powder;) *potassio-citrate of antimony*, (dazzling white prisms.)

CITRATE, OR AMMONIO-CITRATE OF IRON. *Syn.* AMMONIO-CITRATE OF PEROXIDE OF IRON. FERRO-CITRATE OF AMMONIA. PERCITRATE OF IRON AND AMMONIA. There are three salts generally known under this name—two, having the peroxide for their base, and one, the protoxide. There is also a fourth, formed from the magnetic oxide of iron, which has scarcely been introduced into this country, though commonly employed in France, and highly recommended by Béral. The salt at present so much advertised as citrate of iron, is a double citrate of iron and ammonia—an ammonio-citrate, and as such I shall describe it. I find that several other double citrates of iron may be prepared, but they are possessed of inferior qualities to those just mentioned. They therefore offer no inducement for their manufacture.

I. This salt is most conveniently formed by dissolving moist hydrated peroxide of iron in liquid citric acid, (pure,) assisting the solution by heat, and then bringing it to a perfectly neutral state by the addition of a little sesquicarbonate of ammonia. It must then be filtered, cooled, and spread very thinly on warm sheets of glass to dry, which it will rapidly do, and may then be easily detached from the glass, in thin scales, or lamellæ, of great brilliancy and beauty. Only a gentle heat must be employed, not exceeding that of a water-bath. This is the mystery of producing those beautiful transparent ruby-colored scales which are so much admired.

II. Competition in the sale of this article has induced the manufacturer to adopt a cheaper formula than that originally published by Béral and employed by many houses. It is now generally prepared by placing together, for some days, in a warm situation, a mixture of iron filings, and citric acid in powder, with barely sufficient water to cover them, occasionally stirring and replacing the water as it evaporates. A saturated solution is made in distilled water, there being previously added more citric acid, (about half the weight of the acid first used,) if required; it is then neutralized with liq. ammon. fort., (about 1¼ oz. of liquor of ammonia, sp. gr. ·882, to every gallon of the solution of sp. gr. 1·025,) and concentrated by evaporation: the same plan mentioned above is then followed, to complete the process. The first part of this process produces a salt of the protoxide of iron, which is afterwards converted, by exposure to the atmosphere, into a citrate of the magnetic oxide, and lastly into citrate of peroxide of iron.

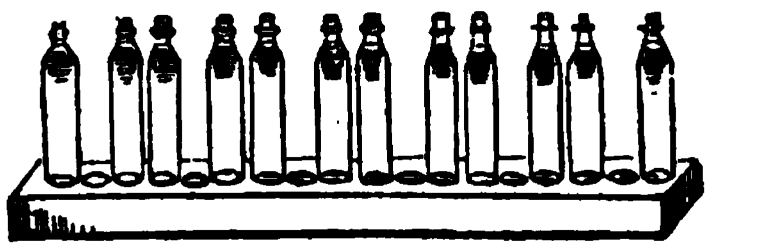
Remarks. This beautiful salt is of a rich ruby color, and may be obtained under the form of glistening transparent scales, very soluble in aqueous menstrua, while its solution is not so easily decomposed as that of many other salts of iron. It is nearly tasteless, and highly deliquescent. The absurd statements put forth in advertisements respecting this preparation being compatible with the volatile and fixed alkalis and their carbonates, &c., I find to be incorrect; for on adding some liquor potassæ to a solution of this salt, it immediately became turbid, exhaled ammonia in large quantities, and deposited oxide of iron. I found the same take place with the carbonate; and no doubt, had I extended the experiments to the other articles mentioned as compatible, I should have met with another similar result. It is doubtful whether this article has not obtained a larger sale from its pleasing appearance, than from its medicinal virtues. I know several parties who have prepared this salt in lumps or powder, by simple evaporation of the solution to dryness, who have been unable to sell it under that form, even at a lower price.

M. Béral, in his directions for the preparation of this salt, directs a platina capsule to be used, as well as attention to other minutiæ, which I find quite unessential to the success of the operation. Glass, Wedgewood ware, or even metallic vessels may be employed; the former, however, are preferable. I find that boiling water will dissolve about twice its weight of citric acid, and retain $\frac{1}{2}\frac{1}{0}$ of this quantity in solution when cold, and that it takes rather more than twice the weight of the citric acid, in most hydrated protoxide of iron, to produce saturation.

We may, therefore, with great advantage, em-

This forms the proof solution, which, if mixed with 6 or 8 parts of water, is quite colorless, but chloride of lime occasions the production of peracetate of iron, which gives it a red color.

The above proof-solution is then poured into 12 two-oz. vials, of exactly equal diameters, to the amount of $\frac{1}{5}$ of their capacity; these are filled up with bleaching liquid of various strengths; the first at $\frac{1}{12}$ of a degree of Twaddle, the second $\frac{2}{12}$, and so on up to $\frac{12}{12}$ or 1°. They are then well corked up, and, after agitation, arranged side by side on a tray, furnished with holes to receive them, in the manner represented in the engraving. A se-



ries of test vials are thus formed, showing the various shades of color that the solutions of the given strengths are capable of producing. To ascertain the strength of an unknown sample of bleaching liquor, the proof solution of iron is put into a vial, exactly similar to the 12 previously used, and in precisely the same proportion, ($\frac{1}{5}$.) The vial is then filled up with the bleaching liquor, well shaken, and placed beside that one of the 12 already prepared which it most resembles in color. The number on that vial expresses the strength of the sample under examination, in $\frac{1}{12}$ths of a degree of Twaddle's hydrometer.

Table exhibiting the quantity of Bleaching Liquid, at 6° on Twaddle's scale, (sp. gr. 1·030,) required to be added to a weaker liquor, to raise it to the given strengths. Adapted from Mr. Crum's table by Mr. Cooley.

Strength of sample in $\frac{1}{12}$°.	Required Strength.	Proportions required. Given Sample.	Liquor at 6°.
		Parts.	Part.
Water.	$\frac{8}{12}$°	8	1
1	do.	$9\frac{1}{4}$	1
2	do.	11	1
3	do.	$13\frac{1}{2}$	1
4	do.	17	1
5	do.	23	1
6	do.	35	1
7	do.	71	1
Water.	$\frac{6}{12}$°	11	1
1	do.	$13\frac{1}{2}$	1
2	do.	17	1
3	do.	23	1
4	do.	35	1
5	do.	71	1
Water.	$\frac{4}{12}$°	17	1
1	do.	23	1
2	do.	35	1
3	do.	71	1
Water.	$\frac{3}{12}$°	23	1
1	do.	35	1
2	do.	71	1

Remarks. The preceding method is admirably suited for weak solutions, such as are employed for bleaching textile fabrics, and is well adapted (from its simplicity) to the purposes of practical men. It is employed in many of the Scotch bleaching houses.

According to Mr. Crum, the range of strength within which cotton is safe, is very limited. A solution at 1° of Twaddle's scale, (sp. gr. 1·005,) is not more than safe, while one at $\frac{1}{2}$° is scarcely sufficiently strong for the first operation on stout cloth, unless it be packed more loosely than usual. (Trans. Glasgow Phil. Soc.)

III. (*Ure's test.*) This consists in adding water of ammonia of a known strength, tinged with litmus, to a solution of a given weight of the chloride, until the whole of the chlorine be neutralized, which is known by the color ceasing to be destroyed. From the quantity of ammonia consumed, the strength is estimated. During the above process azote is evolved, and the estimation of the volume thus liberated has been proposed as another easy method of chlorimetry by Dr. Ure.

This gentleman recommends the two substances to be mixed in an inverted and graduated syphon tube over mercury. (See Engraving.) "The shut end *a* and the open end *b*, are both graduated to one scale; for example, to $\frac{1}{100}$ of an inch, or to grain or 10 grain measures. The tube is to be filled with mercury, and then 10 measures of it are to be displaced at the open end, by inserting a wooden plug. This space being filled with a solution of a given weight of chloride of lime, is to be turned up into the shut end, by covering the open end with the finger and inverting the tube; a few drops of water may be sent through to wash the mercury. The ammonia being now let up will cause a reaction, and evolve a quantity of azote, equivalent to the chlorine present. The action may be accelerated by holding the sealed end of the tube over the flame of a spirit-lamp. The mercury is protected from the chlorine by the ammonia; and should any notion be entertained of such an action, the ammonia may be let up first. I have made innumerable researches over mercury, with a detached apparatus of this kind, which combines precision with rapidity of result." (Ure's Dict. Arts.)

IV. (*Process of M. Gay Lussac.*) One part of the best indigo is dissolved in 9 parts of strong sulphuric acid, by the aid of a gentle heat. This solution is then mixed with distilled water, in such proportion, that 1 volume of chlorine gas shall exactly decolor 10 volumes of this solution. Each measure so decolored is called a degree, and each degree is divided into fifths. 5 grains of the best chloride of lime, dissolved in 500 grain measures of water, will possess the above power, and indicate 10° or proof, and will decolor 10 times its volume of the indigo solution. The objections to this method of chlorimetry are, that the indigo solution alters by keeping, and that it is not adapted for testing strong solutions of chloride of lime. "I have tried the indigo test in many ways, but never could confide in it." (Ure.)

CHLORO-NITROUS GAS. A gaseous compound, discovered by E. Davy. It is obtained

by treating fused chloride of sodium, potassium, or calcium, in powder, with as much strong nitric acid as is sufficient to wet it, when this gas is evolved. *Prop.* It has an orange color, smells like chlorine, and bleaches. Soluble in water.

CHLOROPHYLL. *Syn.* CHLOROPHILE. CHLOROPHYLE. The green coloring matter contained in the leaves, stalks, unripe fruit, and juices of most plants. It is extracted by ether, and purified by successive solutions in alcohol and muriatic acid; from the last it is precipitated pure by water.

Prop. A dark green mass, producing a grass-green powder. It is soluble in ether, alcohol, acids, alkalis, and oils. If an earthy or metallic salt be mixed with the alcoholic solution, and an alkaline carbonate be added, the earth or oxide is thrown down in combination with this coloring matter, forming a green lake, possessing considerable permanency. Pelletier and Caventou, who first discovered chlorophyll, obtained it by simply pressing the leaves, washing in water, and afterwards treating it with alcohol.

CHLOROUS ACID. *Syn.* PEROXIDE OF CHLORINE. A compound of oxygen and chlorine. *Prep.* Chlorate of potassa in fine powder, made into a paste with strong sulphuric acid, is put into a retort and heated in a water-bath, hot but not boiling. A yellowish green gas is given off, which may either be collected in dry bottles, or passed into water, when it will form liquid chlorous acid.

Props., &c. Its aqueous solution undergoes gradual decomposition, yielding chlorine and chloric acid. It possesses powerful oxidizing and bleaching properties, and unites with the bases forming salts called chlorites. These are all soluble in water, and possess bleaching powers like the acid. They may be recognised by the evolution of chlorous acid gas when acted on by an acid.

CHOCOLATE. *Syn.* CHOCOLADA. CHOCOLAT, (*Fr.*) The roasted cacao nut made into a paste by triturating it in a heated mortar, with sugar and aromatics, and cast in tin moulds, in which it concretes into cakes on cooling. The term is derived from two Indian words, *choco*, sound, and *atte*, water; because of the noise made in its preparation. (Dr. Alston.)

Qual. Chocolate is nutritive and wholesome, if taken in moderation, but is sometimes apt to disagree with weak stomachs, especially those that are easily affected by oily substances or vegetable food. The quantity of aromatics mixed with the richer varieties, improve the flavor, but render them more stimulant and prone to produce nervous symptoms, and complaints of the head.

Prep. The nuts are first roasted, (on the small scale this may be done in a frying-pan,) and after being cleared from the husks, reduced to coarse powder; they are then beaten in an iron mortar, the bottom of which is heated, until they are reduced to a paste, which is effected by the action of the heat on the oil or butter they contain. This paste or semi-fluid mass is then poured out into moulds, and left until cold, when it forms *cake chocolate*, or *chocolate paste;* or it may be reduced to coarse powder, by grinding, when it is known under the name of *chocolate powder*.

Remarks. Chocolate, prepared as above, without the addition of aromatics, is known in the trade as *plain chocolate*. The Spaniards flavor it with vanilla, cloves, and cinnamon, and frequently scent it with musk and ambergris. In general, they add too large a quantity of the last four articles. The Parisians, on the contrary, use but little flavoring, and that principally vanilla. They employ the best caracca nuts, and add a considerable quantity of refined sugar.

The mass of the common chocolate sold in England, is prepared from the cake left after the expression of the oil, and this is frequently mixed with the roasted seeds of ground peas, and maize or potato flour, to which a sufficient quantity of inferior brown sugar, or treacle and mutton suet is added, to make it adhere together. In this way is made the article commonly marked in the shops at 8*d.*, 9*d.*, and 10*d.* the pound. I know a person who lately bought a large quantity at 5*d.*, whereas good nuts, in their unprepared state, cost at wholesale more than double the money.

To excel in the manufacture of chocolate requires some little experience. The roasting of the nuts must be done with great care, and the process stopped as soon as the aroma is well developed. They should then be turned out, cooled, and fanned from the husks. On the large scale, chocolate is made in mills, worked by steam power, and the machinery employed in the grinding, admirably fulfils its duty.

The South American beans are esteemed the best for making chocolate. Like wine, it improves by age, if kept in a dry but not too warm a place.

CHOCOLATE CREAM. *Prep.* Chocolate scraped fine 1 oz.; thick cream 1 quart; sugar (best) 6 oz.; heat it nearly to boiling, then remove it from the fire, and mill it well. When cold, add the whites of 8 or 10 eggs; whisk rapidly, and take up the froth on a sieve; serve the cream in glasses, and pile up the froth on the top of them.

CHOCOLATE DROPS. Reduce 1 oz. of chocolate to fine powder by scraping, and add it to 1 lb. of finely-powdered sugar; moisten the paste with clear water, and heat it over the fire until it runs smooth, and will not spread too much when dropped out; then drop it regularly on a smooth plate. Avoid heating it a second time.

CHOCOLATE FOR ICING. *Syn.* SORBET AU CHOCOLAT. *Prep.* Rub 2 oz. of chocolate to a paste with 2 tablespoonfuls of hot milk, then add cream for icing 1 quart. Ice as wanted for use.

CHOCOLATE FOR THE TABLE. *Prep.* Put the milk and water on to boil; then scrape the chocolate fine, from one to two squares to a pint, to suit the stomach: when the milk and water boils, take it off the fire, throw in the chocolate, mill it well, and serve it up with the froth, which process will not take five minutes. The sugar may either be put in with the scraped chocolate, or added afterwards.

It should never be made before it is wanted; because heating again injures the flavor, destroys the froth, and separates the body of the chocolate; the oil of the nut being observed, after a few minutes' boiling, or even standing long by the fire, to rise to the top, which is the only cause why chocolate can offend the most delicate stomach.

CHOCOLATE, FRENCH. *Prep.* Finest ca-

The cheese is next turned out and surrounded by a fres i cheese-cloth, and pressure again applied for 8 or 10 hours, when it is commonly removed from the press, salted all over, and pressed again for 15 to 20 hours. The quality of the cheese especially depends on this part of the process, as if any of the whey be left in the cheese, it will not keep, but will rapidly become bad-flavored. Before placing it in the press the last time, the edges should be pared smooth and sightly. It now only remains to wash the outside of the cheese in warm whey or water, wipe it dry, and color it with annotto as is usually done.

There are several methods of collecting the curd adopted, and as the flavor of the cheese varies accordingly, it is as well to notice them. One way is to break the curd early, and to remove the whey as soon as possible; another plan is to gather it with the hands very gently towards the sides of the tub, letting the whey run off through the fingers until it becomes cleared, and ladling it off as it collects. A third method is to remove it as quickly as possible with the curd-skimmer. Of these the second plan is said to be the best, as it preserves the oily particles, many of which are lost by the other methods.

The cheese being made, it now only remains to place it in a proper situation to mature or ripen. In England a *cool, and slightly damp cellar*, is commonly regarded as the best to bring it forward. The temperature should on no account exceed 50° at any portion of the year, but an average of about 45° is preferable when it can be procured. A place exposed to sudden changes of temperature is unfit for storing cheese. "The quality of Rochefort cheese, which is prepared from sheep's milk, and is very excellent, depends exclusively upon the places where the cheeses are kept after pressing and during maturation. These are cellars, communicating with mountain grottoes and caverns, which are kept constantly cool, at about 41° to 42° Fahr., by currents of air from clefts in the mountains. The value of these cellars as storehouses varies with their property of maintaining an equable and low temperature. Giron (Ann. de Chim. et Phys. xlv. 371) mentions that a certain cellar, the construction of which had cost 480*l.*, (12,000 francs,) was sold for 8,600*l.*, (215,000 francs,) being found to maintain a suitable temperature, a convincing proof of the importance attached to temperature in the preparation of these superior cheeses." (Liebig's Lectures.)

It will thus be seen that very slight differences in the materials, the preparation, or the storing of cheese, will materially influence the quality and flavor. The richness of the milk,—the addition to or subtraction of cream from the milk,—the separation of the curd from the whey with or without compression,—the salting of the curd,—the collection of the curd, either whole or broken, before pressing,—the addition of coloring matter, as annotto or saffron, or of flavoring,—the place and method of storing,—and the length of time allowed for maturation, all tend to alter the taste and odor of the cheese, in some or other particular, and that in a way readily perceptible to the refined palate. The nature of the pasture or the food on which the cows are fed, as well as their particular breed, no doubt also tends in some slight degree to promote the same diversity of flavor and quality. No other alimentary substance appears to be so materially affected by slight variations in the quality of the materials from which it is made, or by such apparently trifling differences in the methods of preparing it.

Var. There are several varieties of cheese met with in trade, differing from each other in quality or flavor; and these are generally distinguished by the names of the places where they have been manufactured, and sometimes, though more rarely, by their flavor, or the milk from which they are manufactured. Three divisions may however be made, depending upon the quality of the materials, each of which is well marked, and to one or the other all kinds of cheese belong. These are *skimmed-milk, raw-milk*, and *cream cheeses*, the names of which respectively express the materials of which they are made. The following are the principal cheeses met with in Europe.

Brickbat cheese, made in Wiltshire of new milk and cream. This name is given to it from its being made into forms resembling brickbats.

Chedder cheese, named after the place where it is made. This is a fine kind of cheese, with a spongy appearance, the eyes or vesicles of which contain a rich oil. It is made up into round thick cheeses of considerable size.

Cheshire cheese. The best Cheshire cheese is made of new milk without skimming, the morning's milk being mixed with that of the preceding evening, previously warmed, so that the whole may be brought to the heat of new milk. To this the rennet is added, in less quantity than is commonly used for other kinds of cheese. On this point, much of the flavor and mildness of the cheese is said to depend. A piece of dried rennet, of the size of half-a-crown, put into a pint of water over night, and allowed to stand until the next morning, is sufficient for 18 or 20 gallons of milk. The curd is next broken down and separated from the whey, after which it is put into a cheese vat and pressed very dry. It is next broken very small with the hands, and mixed with a proper quantity of salt, and about half its weight of curd, from yesterday's batch, kept for the purpose. The mixed curds are now pressed tightly with the hands, into a cheese-vat, previously lined with cheese cloth, pressed for 4 or 5 hours, then taken out, turned, and again put into the press and left for the night. It is taken out next morning, well salted, and left until the salt is quite melted, when it is wiped dry, placed in a dry, cool situation, and turned every day until it becomes fit for the market.

"If the milk be set together very warm, the curd will be firm: in this case, the usual mode is to take a common case-knife, and make incisions across it, to the full depth of the knife's blade, at the distance of about 1 inch; and again crosswise in the same manner, the incisions intersecting each other at right angles. The whey rising through these incisions is of a fine pale green color. The cheese-maker and two assistants then proceed to break the curd: this is performed by their repeatedly putting their hands down into the tub; the cheese-makers, with the skimming-dish in one hand, breaking every part of it as they catch it, raising the curd from the bottom, and still breaking

it. This part of the business is continued till the whole is broken uniformly small; it generally takes up about 40 minutes, and the curd is then left covered over with a cloth for about half an hour to subside. If the milk has been set cool together, the curd, as before mentioned, will be much more tender, the whey will not be so green, but rather of a milky appearance." (Cheshire County Agricultural Report.)

Cream cheese. This is either made of the "strippings," (the last of the milk drawn from the cow at each milking,) or of a mixture of milk and cream. It is usually made up into small pieces, and a gentle pressure, as that of a 2 or 4 lb. weight, applied to press out the whey. After twelve hours, it is placed upon a board or wooden trencher, and turned every day, until dry. In about three weeks, it will be ripe. Nothing but raw cream, turned with a little rennet, is employed, when a *very rich* cheese is wanted. A little salt is generally added, and frequently a little powdered lump sugar. The vats employed for cream cheeses are usually square, and of small size.

Cottenham cheese, named from the town where it is made, is a species of cream cheese, superior to Stilton, from which it also differs in shape, being flatter and broader than the latter. Its superiority is said to be derived from the rich grasses growing on the fens of Cambridgeshire.

Derbyshire cheese is a small rich variety, of a pale color, very similar to the following:

Dunlop cheese, named after a town in Ayrshire, where it was originally made. It is very rich, white, and buttery, and is made up into round forms, weighing from ¼ cwt. to ½ cwt. It is now made very generally throughout the whole of Scotland.

Dutch cheese. This is very commonly met with in England, and is readily distinguished by its globular form. The cheeses made at Edam are very highly salted; those made at Gouda are less so. The common size of these cheeses is from 5 to 14 lbs.

French cheese. The Rochefort and the Neufchatel are the most esteemed.

German cheese. The only kind made in Germany of any celebrity, is the *Westphalian,* which derives its peculiar flavor from the curd being allowed to become partially putrid before being pressed. It is made up into small balls or cylinders, of about a pound weight, somewhat resembling in shape the pounds of butter in some parts of the west of England.

Gloucester cheese. There are two varieties of this cheese: *the single,* made of milk deprived of part of its cream, and *the double,* made of milk retaining the whole of the cream. The best kind has a fine mild taste; a semi-buttery consistence, without being friable, and is made up into large round flattish forms.

Green or sage cheese is made from milk previously mixed with the juice or an infusion or decoction of sage leaves, to which some marygold flowers and parsley are frequently added.

Lincolnshire cheese is made of new milk and cream, and formed into pieces about 2 inches thick. It is very soft, and without great care, will not keep over two months. Some persons sprinkle dry salt over them, when they will keep better.

Norfolk cheese. This is remarkable for the curd being dyed yellow, with annotto or saffron. It is of very good but not superior quality, and usually weighs from ¼ to ½ cwt.

Neufchatel cheese. After Rochefort cheese, this is the best manufactured in France. It is made of cream, and seldom exceeds 5 or 6 oz. in weight.

Parmesan cheese. This is made at Parma, and in other parts of Lombardy. Its peculiar flavor is said to arise from the luxuriance of vegetation in that part of Italy, and from the great abundance of aromatic flowers in the pastures. It is more probable, however, that the application of heat to the curd of the milk, to harden it, as is the common practice in Lombardy, is the true cause of its flavor. The following method is said to produce a cheese equal to the best Parmesan:

"Let the day's milk be heated to the degree of 120° of Fahrenheit, then removed from the fire until all motion ceases, put in the rennet, allow an hour for the coagulation, after which set the curd on a slow fire until heated to 150°, during which the curd separates in small lumps. A few pinches of saffron are then thrown in, together with cold water sufficient to reduce it instantly to a bearable heat, when the curd is collected by passing a cloth beneath it, and gathering it up at the corners. Place the curd in a circle of wood without a bottom; lay it on a table covered by a round piece of wood, pressed down by a heavy stone. The cheese will acquire sufficient consistence in the course of a night to bear turning, when the upper side is to be rubbed with salt, and continued alternately for forty days."

"In Italy, the outer crust is next cut off, and the new surface varnished with linseed oil; but that may well be omitted, as well as coloring one side of it red."

Polish cheese. This is generally of very inferior quality, and made in imitation of English cheese.

Rochefort cheese. This is made of ewe's milk, and is the best kind prepared in France. It resembles Stilton, but is scarcely of equal richness or quality. By kneading the gluten of wheat with a little salt, and a small portion of a solution of starch, it acquires the taste, smell, and unctuosity of cheese; so that after it has been kept a certain time, it is not to be distinguished from the celebrated Rochefort cheese, of which it has all the pungency. (Roulle.) See the remarks on the Principles of Cheesemaking, above.

Russian cheese. This is generally of a very inferior kind. The best sort is that made in imitation of English cheese; the commoner kinds merely consist of salted curd, placed in a bag and wrung dry, by two persons twisting the ends in opposite directions. It is usually not only bad tasted, but dirty.

Slipcoat or soft cheese is a very rich white cheese, somewhat resembling butter, made for present use.

Stilton cheese, named after the town where it was originally made, is at once the richest and finest variety of cheese manufactured in England. It is prepared from raw milk, to which cream taken from other milk is added. Its shape is peculiar, being generally twice as high as it is broad. It is generally twice the price of Cheshire or dou-

ble Gloucester. Like wine, this cheese is vastly improved by age, and is therefore seldom eaten before it is two years old. A spurious appearance of age is sometimes given to it by placing it in a warm damp cellar, or by surrounding it with masses of fermenting straw, or rotten cow-dung.

Suffolk cheese is made from skimmed milk, and is usually shaped into round flat forms, weighing from 24 lbs. to 30 lbs. each. It much resembles the skimmed or "scald" milk cheese made in Devonshire.

Swiss cheese. The principal cheeses made in Switzerland are the Gruyère, or Jura, and the *Schabzieger*, or *green cheese*. The latter is flavored with melilot.

Wiltshire cheese resembles poor Cheshire or Glo'ster. The outside is generally covered with red paint, made by mixing up ruddle or red ochre with whey, and laying it in with a brush.

Yorkshire cheese is a fine variety of cream cheese, but will not keep.

Concluding Remarks. It is surprising that cheese is not more frequently made an article of domestic manufacture, especially by housewives resident in the country. The operations of cheese-making are all exceedingly simple, and not at all laborious, and will, in most cases, amply repay the outlay for the milk. With the peasantry, who can usually procure a few gallons of milk from the houses of the farmers for whom they work, it really appears a want of common foresight, not to provide themselves with a few pounds of this wholesome and nutritious article, which is looked upon by some of those roughly-fed children of the soil, as a luxury beyond their reach. In a family where cheese is generally relished by the majority of the members, it becomes quite as necessary to have home-made cheese as home-made bread, and there is scarcely a portion of the United Kingdom where milk may not be obtained, during the summer months, at such a price as to render it important in a pecuniary point of view. Besides, cheese is not unfrequently colored with stains and pigments which are injurious, and even poisonous. Several persons have nearly lost their lives, from eating cheese colored with annotto, for instance. This dye is commonly adulterated with red-lead, so that the farmer (cheesemaker) may very innocently introduce a dreadful poison, when he only intends to improve the color. By making our own cheeses, the liability to such an accident is avoided.

When a whole cheese is cut, and the consumption small, it is generally found to become unpleasantly dry, and to lose flavor before it is consumed. This is best prevented by cutting a sufficient quantity for a few days' consumption from the cheese, and placing the remainder in a cool place, rather damp than dry, spreading a thin film of butter over the cut surface, and covering it with a cloth to keep off the dirt. This removes the objection existing in small families against purchasing a whole cheese at a time. The common practice of buying small quantities of cheese should be avoided, as not only a higher price is paid for any given quality, but there is little likelihood of obtaining exactly the same flavor twice running. Should cheese become too dry to be agreeable, it may be used for stewing, or when grated cheese is wanted.

Toasted cheese is much relished by some persons, but is seldom met with well prepared. The following has been handed to the writer by the cook of a certain nobleman who prides himself on his gustful appetite. Cut the cheese into slices of moderate thickness, and put them into a tinned copper saucepan, with a little butter and cream, simmer very gently until quite dissolved, then remove it from the fire, allow it to cool a little, and add some yelk of egg, well beaten; make it into a shape, and brown it before the fire.

CHELTENHAM SALTS. *Prep.* Glauber salts 1 oz.; Epsom salts ¾ oz.; culinary salt a teaspoonful; sulphate of iron 2 grs.; reduce them separately to fine powder, then mix them.

II. Glauber salts and Epsom salts, of each 28 lbs.; common salt 7 lbs.; sulphate of iron 1¼ oz.; mix.

Remarks. The above salts must be dried in an oven, or over the fire, before reducing them to powder. The Glauber's should be dried by itself, as it liquefies when slightly heated. Cathartic and tonic. *Dose.* ½ oz. to 1½ oz.

CHELSEA PENSIONER. *Prep.* Gum guaiacum ¼ oz.; rhubarb ½ oz.; cream of tartar 2 oz.; flowers of sulphur 4 oz.; nutmegs 2 in number, (all in powder;) honey 1½ lb.; make them into a confection by beating them together in a mortar.

Remarks. The dose is two tablespoonfuls, night and morning, in rheumatism. The name is said to have been given to it from the circumstance of a Chelsea pensioner having cured Lord Amherst with it.

CHILBLAIN. An inflammatory swelling, of a purple or lead color, produced by the action of cold. Children, especially those of a scrofulous habit, and elderly persons, are generally most liable to chilblains. The common cause of chilblains is holding the hands or feet to the fire, after exposure to cold. The sudden change of temperature partially destroys the vitality, and prevents the proper flow of blood through the part. The best preventives of chilblains are woollen socks or stockings, good waterproof shoes, woollen gloves, exercise, and friction. *When chilblains have once formed*, the best treatment is friction, with stimulants, as spirits of wine and camphor, turpentine, opodeldoc, dilute spirits, camphorated oil, &c. Linnæus recommends bathing the part with dilute muriatic acid, just strong enough to faintly prick the skin. When the inflamed parts have ulcerated, they are commonly called *kibes*. In this state they should be dressed with a little resin cerate, or elemi ointment, and if fungous granulations appear, they must be removed by touching them with nitrate of silver or blue vitriol.

CHILBLAINS, LOTIONS FOR, (POPULAR.) I. Dissolve white copperas 1 oz. in water 1 pint, and occasionally apply it to the affected parts.

II. Dissolve sal ammoniac 1 oz. in vinegar ½ pint; as above.

III. Mix compound soap liniment 2 oz. with tincture of Spanish flies 1 oz.; as above.

IV. Vinegar and spirit of wine, (or rum,) of each ½ pint; sal ammoniac, in powder, 1 oz.; mix and shake until the latter dissolves.

V. Spirits of salts 1 oz.; water ½ pint; mix; as above.

CHILBLAINS, OINTMENT FOR. *Prep.* Ointment of nitrate of mercury 1 oz.; camphor 1 dr.; oil of turpentine 2 drs.; oil of olives 4 drs.; mix well together. To be applied, by gentle friction, 2 or 3 times daily.

II. Calomel and camphor, of each 1 dr.; spermaceti ointment 4 drs.; oil of turpentine 2 drs.; as last.

Remarks. All the preceding lotions and ointments are intended for chilblains before they break.

CHILBLAINS, RUSSIAN REMEDY FOR. A common remedy for chilblains among the peasants in Russia is the rind of perfectly ripe cucumbers, dried with the soft parts attached, and placed with the inner side, previously soaked in warm water, over the sore parts. Dumitriefsky confirms the efficacy of this remedy. (Med. Zeitung.)

CHIMNEYS ON FIRE may be readily extinguished in several ways, without having recourse to throwing water down them from the top, by which much damage is frequently done to the furniture in the rooms. One of the simplest methods is, to scatter a handful of flowers of sulphur over the dullest part of the burning coals, the mephitic vapors arising from which will not support combustion, and consequently extinguish the flames. *Another* method is, to shut the doors and windows, and to stop up the bottom of the chimney with a piece of wet carpet or blanket, throwing a little water or flowers of sulphur, or salt, on the fire immediately before doing so. By this means the draught is stopped, and the burning soot must be extinguished for want of air. If the chimney be stopped at top, instead of the bottom, the whole of the smoke must, of course, be driven into the apartment. If every fireplace were provided with a damper, or shutter of sheet-iron or tin plate, sufficiently large to choke it thoroughly, fires in chimneys would become of little consequence, as it would only be necessary to apply this damper to put them out.

CHINA, (CHOICE OF.) In purchasing china, glass, and earthenware, care should be taken to select those sets that in case of breakage can be readily matched. Peculiar or rare patterns should be avoided, for if any such be broken, it will generally be found very difficult and expensive, and frequently impossible, to replace them.

Cleaning. China (when very dirty) is best cleaned with finely-powdered fuller's earth and warm water, afterwards rinsing it well in clean water. A little clean soft soap may be added to the water instead of fuller's earth. The same plan is recommended for cleaning glass.

Packing. As there is considerable art in packing brittle hollow-ware, in such a way that it will stand exposure to the jolting, blows, and agitation of land-carriage, it is better, where it is of much value, or in quantity, to have it done by a person used to the job. A man, accustomed to packing such articles, may be readily procured at any glass-works, or china warehouse, for a trifling consideration.

CHINA-ROOT STARCH. A reddish-colored farina, procured from the smilax china.

CHINESE SHEET-LEAD. The Chinese employ large quantities of sheet-lead in packing their tea, which they make in the following way:—Melted lead is poured from a crucible upon a large flat stone, placed upon the ground, and immediately another stone is dashed upon the fluid lead, which is thus pressed out into a very thin plate or leaf. This is instantly removed, and the operation repeated as rapidly as possible. The rough edges of the plates are afterwards cut off, and then soldered together for use. The Chinese employ two men in this process; one to pour on the melted lead, and the other to work the stone. A similar method has been adopted for some years in England, to form the plates of zinc for galvanic batteries.

CHIRAYITINE, SULPHATE OF. The substance sold under this name is sulphate of quina. Chirayita yields no alkaloid, but merely a bitter matter.

CHLORAL. A substance prepared by the action of chlorine on alcohol.

Prep. Place anhydrous alcohol in a tubulated retort, and pass dry chlorine gas through it, at first in the cold, but afterwards with the application of a gentle heat. As soon as the chlorine passes undecomposed through the liquor at the boiling temperature, the process is complete. On cooling, the liquid in the retort solidifies, forming a crystalline mass of hydrated chloral. This must be melted by gentle heat, and agitated with thrice its volume of oil of vitriol, when, on increasing the heat a little, an oily stratum of impure chloral will rise to the surface. This must be removed, boiled for some time, to drive off some free hydrochloric acid and alcohol, and next distilled with an equal volume of oil of vitriol; lastly, it must be rectified from finely-powdered quicklime, stopping the process as soon as the surface of the lime becomes dry.

Remarks. The chlorine is best introduced by a tube inserted into the tubulature of the retort, and a long tube, bent upwards, should be connected with the beak to convey away the hydrochloric acid gas extricated, and to allow the volatilized alcohol and chloral to condense and flow back into the retort.

Prop. Chloral is an oily liquid, possessing an ethereal smell; it is soluble in alcohol, ether, and water, but its solution in the latter rapidly changes into a semi-solid crystalline mass of hydrate of chloral, soluble in a larger quantity of water. Chloral boils at 202°, and has a sp. gr. of 1·502.

CHLORATE. A compound of chloric acid with a base. The chlorates are very similar to the nitrates, both in their properties and composition. They are all decomposed at a red heat, metallic chlorides being formed, and oxygen gas given off. Like the nitrates, they deflagrate with inflammable substances, but with greater facility and violence. A mixture of this kind will detonate with a slight blow or friction. All the chlorates are soluble in water.

Tests. Rubbed with sulphur, or phosphorus, they explode violently; mixed with muriatic acid, and then with water, a liquid is formed, possessing bleaching properties. When heated, they evolve oxygen. Thrown on red-hot coals, they deflagrate like nitre. Sulphuric acid turns them orange red. The following simple method of testing the commercial chlorates has been proposed by M. Choron:

is added about 5% of perfectly tasteless rectified spirit of wine.

COFFEE FOR ICING. *Syn.* SHORBET AU CAFE. Cream for icing 1 quart; strong infusion of coffee a small teacupful; sugar 2 oz.; yelks of 4 eggs. Mix, and ice as wanted.

COFFEE FOR THE TABLE. To produce the beverage called coffee, in perfection, it is necessary to employ the best materials in its manufacture. The finest kind of coffee is that called mocha, and should be used when a very fine flavor is desired; but for common use, the better sorts of British plantation coffee may be employed. The berries should be carefully roasted by a gradual application of the heat, until the aroma be well developed, and the toughness destroyed. If too much heat be used, the volatile and aromatic properties of the coffee will be injured and the flavor inferior; while, on the other hand, if the berries be too little roasted, they will produce a beverage with a raw, green taste, very liable to induce sickness and vomiting. Properly roasted coffee should have a lively chocolate brown color, and should not have lost more than 18% of its weight by the process. If the loss exeeds 20% the flavor will be materially injured. As soon as roasted, the coffee should be placed in a very dry situation, the drier the better, and the sooner it is consumed the finer will be the flavor, as it powerfully absorbs a certain amount of moisture from the atmosphere by reason of its hygrometric power. This arises from the presence of a newly-discovered principle called assamar. (Reichenbach.) The berries should not be ground until a few minutes before being made into liquid coffee, for the same reason, and should more be reduced to powder at once than is wanted for immediate use, the surplus portion should be kept in a tin canister or glass bottle.

The shape or description of the coffee-pot appears of little consequence, though one furnished with a percolator or strainer, that will permit a moderately rapid filtration, is perhaps preferable. At least 1 oz. of coffee should be used to make 4 common sized coffee-cupfuls, and if wanted *strong*, this quantity should be doubled. The prevailing fault of the coffee made in England, arises from using too little of the powdered berry. The coffee-pot should be heated previously to putting in the coffee, which may be done by means of a little boiling water. The common practice of boiling coffee is quite unnecessary, for all its flavor and aroma is readily extracted by boiling hot water. Should it, however, be placed upon the fire, it should be only *just simmered for a minute*, as long or violent boiling injures it considerably. Hot water is capable of removing all the soluble aromatic portion of coffee, even at a temperature so low as 195° Fahr. I have often proved this by actual experiment with one of Beart's pneumatic filters, when a fluid, deliciously aromatic and sparkling, has been produced, and the grounds have only yielded a nauseous bitter flavor and faint color to fresh water, even when boiling hot.

When coffee is prepared in a common pot, the latter being first made hot, the boiling water should be poured over the powder, and not, as is commonly the plan, put in first. It should then be kept stirred for 4 or 5 minutes, when a cup should be poured out and returned again, and this operation repeated 3 or 4 times, after which, if allowed to repose for a few minutes, it will usually be fine.

Coffee is sometimes clarified, which is done by adding a shred of isinglass, a small piece of clean eel or sole-skin, or a spoonful of white of egg. An excellent plan, common in France, is to place the vessel containing the *made coffee* upon the hearth and to sprinkle over its surface a cupful of cold water, which from its greater gravity descends and carries the foulness with it. Another plan sometimes adopted is to wrap a cloth, previously dipped in cold water, round the coffee-pot. This method is commonly practised by the Arabians in the neighborhood of Yemen and Moka, and is said to rapidly clarify the liquor.

The Parisians, who are remarkable for the superior quality of their coffee, generally allow an ounce to each large coffee-cupful of water, and they use the coffee both newly ground and roasted. A shred of saffron, or a little vanilla, is frequently added. The coffee-pot called *à grecque the cafetière à la belloy, or coffee-biggin*, is commonly employed. This consists of a large coffee-pot, with an upper receptacle made to fit close into it, the bottom of which is perforated with small holes, and contains in its interior two moveable metal strainers, over the second of which the powder is placed, and immediately under the third; upon this upper strainer boiling water is poured until it bubbles up through the strainer; the cover of the machine is then shut close down, and it is placed near the fire; so soon as the water has drained through the coffee the operation is repeated, until the whole intended quantity be passed through. Thus the fragrance and flavor will be retained, with all the balsamic and stimulating powers, and in a few moments will be obtained—without the aid of hartshorn-shavings, isinglass, or whites of eggs—a perfectly transparent infusion of coffee. When the Parisian uses a common coffee-pot, he generally divides the water into 2 parts. The first portion he pours on boiling hot, and allows it to infuse for 4 or 5 minutes, he then pours this off as clear as possible, and boils the grounds for 2 or 3 minutes with the remaining half of the water. After the latter has deposited the sediment it is decanted, and mixed with the infusion. The object of this process is to obtain the whole of the strength, as well as the flavor. The infusion is conceived to contain the latter, and the decoction the former. This plan has been recommended, with some modifications, by Mr. Donovan, and more recently by Dr. Davidson, in L'Expérience.

COFFEE, MILK. Boil a dessert-spoonful of ground coffee in about a pint of milk, a quarter of an hour; then put into it a shaving or two of isinglass, and clear it; let it boil a few minutes, and set it on the side of the fire to fine. This is a very fine breakfast, and should be sweetened with real Lisbon sugar.

"Those of a spare habit, and disposed towards affections of the lungs, would do well to make this their breakfast."

COFFEE, SEARLE'S PATENT. This is prepared by evaporating skimmed milk mixed with one-fortieth part of sugar, at a low temperature, and, when nearly solid, adding a very concentrated essence of coffee, and continuing the evaporation

at a very low temperature, (in vacuo if possible,) until the mixture acquires the consistence of a sirup, paste, or candy. (The latter may be powdered.)

COFFEE, SUBSTITUTES FOR. These are numerous, but the principal are the following:

I. (*Rye coffee. Dillenius's ditto. Hunt's breakfast-powder.*) Rye, roasted along with a little butter, and ground to powder. A good substitute.

II. (*German coffee. Succory ditto. Chicory ditto.*) From succory, as above. *Used* either for or mixed with foreign coffee. The most common adulteration of the latter.

III. (*Rice coffee.*) From rice, as above. A good substitute.

IV. (*Currant coffee.*) From the seeds washed out of the cake left in making currant wine.

V. (*Gooseberry coffee.*) From gooseberry seeds, as the last.

VI. (*Holly coffee.*) From the berries.

VII. (*Egyptian coffee.*) From chickpeas.

VIII. (*Rosetta coffee.*) From fenugreek seeds moistened with lemon juice.

IX. (*Corsican coffee.*) From the seeds of the knee-holly.

X. (*Sassafras coffee.*) From the fruit or nut of the sassafras tree, or from the wood cut into chips. Very wholesome. Much recommended in skin diseases, &c.

XI. (*Raspings.*) The raspings of the crust of loaves, procured at the baker's. Equal to rye coffee.

XII. (*Beech-mast coffee.*) From beech-mast or nuts. Very wholesome.

XIII. (*Acorn coffee.*) From acorns, deprived of their shells, husked, dried, and roasted. A good substitute.

XIV. (*Beet-root coffee.*) From the yellow beet-root, sliced, dried in a kiln or oven, and ground with a little foreign coffee. A good substitute.

XV. (*Bean coffee.*) Horse-beans roasted along with a little honey or sugar. When removed from the fire, a small quantity of cassia-buds is frequently added, and the whole is stirred until cold. Said to be a good substitute.

XVI. (*Almond coffee.*) Rye or wheat roasted along with a few almonds. A very small quantity of cassia-buds improves it. A good substitute.

COINS, IMPRESSIONS FROM. A very easy and elegant way of taking the impressions of medals and coins, not generally known, is as follows: Melt a little isinglass glue with brandy, and pour it thinly over the medal, so as to cover its whole surface; let it remain on for a day or two, till it has thoroughly dried and hardened, and then take it off, when it will be fine, clear, and as hard as a piece of Muscovy glass, and will have a very elegant impression of the coin. It will also resist the effects of damp air, which occasions all other kinds of glue to soften and bend if not prepared in this way. (Shaw.) If the wrong side of the isinglass be breathed on, and gold-leaf applied, it will adhere, and be seen on the other side, producing a very pleasing effect. Isinglass glue, made with water alone, will do *nearly* as well as if brandy be used.

Remarks. Medals may also be copied by surrounding them with a hoop of paper, and pouring on them plaster of Paris (mixed with water to the consistence of cream) to the depth of about ¼ an inch. Melted wax, stearine, fusible metal, or any similar material, may be used in the same way. If it be desired to copy the metal in copper, a mould should be first formed in the above manner, and the metal deposited on its surface by the agency of electricity. (See ELECTROTYPE.)

COLCHICINE. *Syn.* COLCHICINA. COLCHIA. A peculiar principle discovered by Gieger and Hesse in the seeds of the colchicum autumnale, or common meadow saffron. It also exists in the cormi or bulbs.

Prep. Macerate the crushed seeds in boiling alcohol, add hydrate of magnesia to throw down the alkaloid, digest the precipitate in boiling alcohol, and filter. By cautious evaporation colchicine will be deposited. It may be purified by re-solution.

Prop., &c. Odorless; tastes bitter; forms salts with the acids. It is very poisonous. One-tenth of a grain, dissolved in spirit, killed a cat in 12 hours. It differs from veratrine in being soluble in water, crystalline, and the non-production of sneezing when applied to the nose. Strong oil of vitriol turns this alkaloid of a yellowish brown; nitric acid of a deep violet, passing into indigo blue, green, and yellow.

COLCHICUM, POWDER OF. I. (*Collier.*) Seeds of colchicum 2 grs.; rhubarb 6 grs.; magnesia 10 grs.; mix for 1 powder, to be taken every six hours in acute rheumatism, inflammatory gout, &c., washing it down with a glass of Seltzer water, during high febrile action only.

II. (*Collier.*) Seeds of colchicum 3 grs.; muriate of ammonia 5 grs.; for 1 powder. For checking a paroxysm of gout, but its use requires caution. "After all that has been said respecting colchicum in gout, and admitting that it rarely fails to allay pain and check a paroxysm, I would record my opinion that he who would wish to arrive at a good old age, should eschew it as an ordinary remedy, and consider that he is drawing on his constitution for a temporary relief, with a certainty of becoming prematurely bankrupt in his vital energies."

COINDET'S PILLS. *Prep.* Protiodide of mercury 1 gr.; extract of liquorice 20 grs.; mix, and divide into 8 pills. *Dose.* 2 to 4 twice or thrice daily, as an alterative in scrofulous tumors, ulcers, &c.

COLD. When the body of an animal is immersed in an atmosphere at a temperature below the healthy standard, a sensation of coldness is experienced, produced by the passage of the caloric or heat of the body into the colder medium. If this withdrawal of caloric exceed the quantity produced by the vital system, the temperature of the body decreases, until it sinks below the point at which the functions of life can be performed. This declination is gradual; the extreme sensation of coldness changes into a disinclination for voluntary motion; next comes on drowsiness, followed by numbness and insensibility. In this state, if the sufferer be not rescued, and remedial measures had recourse to, death must rapidly follow.

Prevention of the effects of excessive cold.—The extremities of the body first suffer from the action of cold, owing to the circulation of the blood being less vigorous in those parts; they should,

therefore, be properly protected from its action. Woollen stockings or socks, with good shoes or boots, should be worn on the feet, and the body should be clad in thick woollen fabrics, proportioned to the inclemency of the weather, and the habits of the wearer. The circulation of the blood should be promoted by active exercise, and any disposition to sleep shaken off by increased bodily exertion. If the situation be such that exercise cannot be had recourse to, drowsiness is more likely to be experienced, and must be warded off, if possible, by keeping the mind incessantly and actively engaged. The principal endeavor should be to keep the extremities warm, as, if this be accomplished, no danger need be feared. In travelling by coach or on horseback, recourse may be had to hay and straw, which may be thrown over the feet and legs, and will materially ward off the effects of the weather.

Remedial measures for asphyxia produced by intense cold.—The patient should be laid in a room remote from the fire, and bathed with cold salt and water, after which the body should be wiped dry, and friction applied by the hands of the attendants, (warmed;) as many operating at once as can conveniently do so. Gentle stimulants should be administered by the mouth, and the bowels excited by some mild stimulating clyster. The lungs should also be inflated. (See ASPHYXIA.) As soon as symptoms of returning animation are evinced, and the breathing and circulation restored, the patient should be laid in a bed between blankets, and a little wine and water administered, and perspiration promoted by heaping an ample quantity of clothing on the bed. Should the patient have suffered from hunger as well as cold, the appetite may be appeased by the administration of a limited quantity of light food, taking especial care to avoid excess, or any thing indigestible or exciting.

COLIC. (From κωλον, the colon, the supposed seat of the disease.) The colic or bellyache. This name is commonly given to all severe griping abdominal pains, whatever may be the cause. This disease has been distinguished by nosologists into several varieties, as follows:—

I. (*The spasmodic colic.*) This kind is marked by a fluctuating pain about the navel, which goes away and returns by starts, often leaving the patient for some time. The belly is usually soft, and the intestines may often be felt in lumps, which move about under the hand, or wholly vanish for a time. It is unaccompanied by flatulency. *The remedies* are, warm fomentations, warm clysters, and carminatives, accompanied by small doses of camphor and opium.

II. (*The stercoraceous colic.*) This is marked by severe griping pains and constipation of the bowels. *The remedies* are powerful cathartics, as full doses of calomel, aloes, colocynth, jalap, &c., followed by purgative salts, as sulphate of magnesia or soda.

III. (*Bilious colic.*) In this variety the pain is intermittent and transient, accompanied by constipation, nausea, and vomiting. The fæces, if any, are bilious, dark-colored, and offensive. *The remedies* are, a full dose of blue pill, calomel, colocynth, or aloes, followed by a sufficient quantity of epsom or glauber salts. Warm fomentations are also serviceable.

IV. (*Flatulent colic.*) Marked by constipation and the irregular distension of the bowels by gas accompanied by a rumbling noise, &c. It is commonly produced by the use of flatulent vegetables and slops. *The remedies* are, a full dose of tincture of rhubarb combined with a few drops of essence of peppermint. If this does not afford relief, a pill made of 3 grs. of blue pill and 2 grs. of compound extract of colocynth, may be taken, washed down with a glass of any cordial water, as peppermint, cinnamon, or caraway. If the pain be extreme, warm fomentations to the belly, or a carminative clyster may be adopted.

V. (*Accidental colic.*) Produced by improper food and poisons. The treatment differs but little from the last variety.

VI. (*Colica pictonum. Devonshire colic. Plumber's do. Painter's do. Lead do.*) The dry bellyache. This species of colic is marked by obstinate costiveness, acrid bilious vomitings, violent pains about the region of the navel, convulsive spasms in the intestines, and a tendency to paralysis in the extremities. It is most prevalent in the cider counties, and among persons exposed to the fumes of lead. *The remedies* are the same as for the spasmodic variety. Should these fail, after the bowels have been thoroughly evacuated, small doses of camphor and opium may be administered. Mr. Benson, the managing director of the British Whitelead Works at Birmingham, strongly recommends the use of sulphuric acid; he says: "I met with a statement some time since that sulphuric lemonade has been successfully used at a white lead manufactory in France as a preventive of the injurious effects of white lead; and it occurred to me that by adding *sulphuric acid* to the treacle-beer then used by our people, its supposed efficacy might be tested. This idea was carried into effect in the summer of 1841, and the results have proved most gratifying, as, although during several weeks after the addition of the sulphuric acid to the treacle beverage, little advantage seemed to be derived, yet the cases of lead colic became gradually less frequent, and since October of that year, or during a period of fifteen months, not a single case of lead colic has occurred among the people." (Lancet.)

The following is Mr. Benson's form for his treacle or sulphuric beer:—Take of treacle 15 lbs.; bruised ginger ½ lb.; water 12 gallons; yeast 1 quart; bicarbonate of soda 1½ oz.; sulphuric acid (oil of vitriol) 1½ oz. by weight: boil the ginger in 2 gallons of water; add the treacle and the remainder of the water, hot; when nearly cold transfer it to a cask, and add the yeast to cause fermentation; when this has nearly ceased, add the sulphuric acid, previously diluted with eight times its quantity of water, and then add the bicarbonate of soda, dissolved in one quart of water. Close up the cask, and in three or four days the beer will be fit for use. As acetous fermentation speedily takes place, particularly in hot weather, new supplies should be prepared as required.

COLOCYNTHINE. *Syn.* COLOCYNTHITE. COLOCYNTHIUM. The purgative bitter principle of the colocynth.

Prep. Digest the aqueous extract or the pulp of colocynth in alcohol, filter and evaporate the tincture. The residuum is colocynthine combined with acetate of potassa. By agitation with a *little*

water the latter is removed. It may be purified by re-solution in alcohol, and evaporation.

Prop. A yellowish brown translucent resinous substance, very soluble in alcohol, less so in ether, and only slightly so in water. It is intensely bitter, and acts as a drastic purgative.

COLORING. *Syn.* Brewer's Coloring, Brandy do. Spirit do. Essentia Bina. Caramel. *Prep.* Melt brown sugar in an iron vessel over the fire, until it grows black and bitter, stirring it well all the time, then make it into a sirup with water.

Remarks. Some use lime-water to dissolve the burnt sugar. Care must be taken not to overburn it, as a greater quantity is thereby rendered insoluble. The heat should not exceed 430°, nor be less than 400°. The process for nice experiments is best conducted in a bath of melted tin, to which a little bismuth has been added to reduce its melting point to about 435°; a little powdered resin or charcoal, or a little oil being put upon the surface of the metal to prevent oxidizement.

COLORS, COMPOUND. (In Dyeing.) The mixture of blue and yellow dyes produces *green;* red and blue, *violet, purple, lilacs, &c.;* red and yellow, *orange, cinnamon, &c.;* red, yellow, and blue, *olives;* red and blues, or green or black, *browns* of all shades; black mixed with other dyes produces various shades of *brown* and olive, and when pale it constitutes *gray*, either by itself or the addition of a faint blue.

COLOMBIUM. A rare metal, discovered by Mr. Hatchet in 1801, in a black mineral belonging to the British Museum. Supposed to have been brought from America, hence the name. (See Tantalum.)

COLUMBIC ACID. The preceding metal exists in its ores in the form of an acid, united to iron, manganese, or yttria. From these it may be obtained by fusion with 3 or 4 parts of potash, solution in water, and precipitation with an acid. It falls as a white powder or hydrate.

CONCENTRATION. (In Chemistry.) The volatilization of part of a liquid in order to increase the strength of the remainder. The operation can only be performed on solutions of substances of greater fixity than the menstrua in which they are dissolved. Many of the liquid acids, solutions of the alkalis, &c., are concentrated by distilling off their water.

(In Pharmacy.) The term "concentrated" is very commonly applied to any liquid preparation possessing more than the usual strength. Thus we have "*concentrated*" *infusions, decoctions, liquors, solutions, tinctures*, and *essences*, most of which are made of 8 times the common strength. This is generally effected by using 8 times the usual quantity of the ingredients, with a given portion of the menstruum, and operating by digestion or percolation; the latter being generally adopted when the articles are bulky. When the menstruum is water, a little spirit is added to make the product keep.

CONCRETE. (In Architecture.) A compact mass, composed of pebbles, lime, and sand, employed in the foundations of buildings. The best proportions are 60 parts of coarse pebbles, 25 of rough sand, and 15 of lime.

CONDIMENTS. Substances taken with the food, to improve its flavor, or to render it more wholesome or digestible. The principal condiments are common salt, vinegar, lemon juice, spices, aromatic herbs, oil, butter, sugar, honey, and sauces. Most of these, in moderation, promote the appetite and digestion, but their excessive use tends to injure the stomach, and vitiate the gastric juice.

CONFECTIONS. (In Pharmacy.) Medicines, usually pulverulent, mixed up to the consistence of a paste with powdered sugar, sirup, or honey. In the "London Pharmacopœia," both conserves and electuaries are included under this head, though there appears to be some little distinction between them. As remedial agents, the officinal confections possess but little value, and are chiefly useful as vehicles for the administration of more active medicines. In making confections, the sugar requires the same attention as for sirups They should be kept in stone jars, covered with writing paper, and placed in a cool and dry situation. Without this precaution, they are apt to mould on the top. All the dry ingredients employed in making confections should be reduced to a very fine powder, and passed through a sieve not coarser than 80 holes to the inch.

CONFECTION OF ALMONDS. *Prep.* (*Confectio Amygdalæ*, P. L.) Sweet almonds ℥viii; white sugar ℥iv; powdered gum arabic ℥j. Macerate the almonds in *cold* water, then remove the skins, and beat them with the other ingredients until reduced to a smooth confection.

Use. To prepare milk of almonds. A little of this paste or powder, triturated with a sufficient portion of water, and strained through a piece of calico, forms emulsion of almonds.

CONFECTION OF ALKERMES. *Prep.* White sugar 1 lb.; rose-water ¼ pint; clarified juice of alkermes 3 lbs.; oil cinnamon 10 or 12 drops. Mix. It was formerly a common practice to add a little gold-leaf, rubbed small, so as to float about in it; also musk and ambergris.

CONFECTION OF ALUM. *Prep.* (*Conf. Aluminis*, St. B. H.) Alum in fine powder, 80 grs.; conserve of roses, enough to mix. *Use.* As an astringent.

CONFECTION, AROMATIC. *Syn.* Sir Walter Raleigh's Cordial. Confectio Raleighana, (P. L. 1720.) Ditto Cardiaca, (P. L. 1745.) Ditto Aromatica, (P. L. 1788, and since.) *Prep.* I. (P. L.) Nutmegs, cinnamon, and hay saffron, of each ℥ij; cloves ℥j; cardamoms ℥ss; prepared chalk ℥xvj; white sugar lbs. ij. Reduce the whole to a very fine powder, and keep it in a closed vessel. When wanted for use, mix it with water to the consistence of a confection.

Remarks. On the large scale the above form is seldom adhered to. Less saffron is commonly used, cassia is substituted for cinnamon, and, generally, the essential oil for the powder of cloves. Should there be any deficiency of color, this is brought up by a little tincture or infusion of turmeric. When a very smooth and fine powder is desired, it should be passed through a gauze sieve, not coarser than 80 holes to the inch, and precipitated chalk should be employed. The saffron should be dried with as little heat as possible, and care should be taken not to waste any in powdering. The following formula, which is employed by a large whole-

sale druggist in the city, produces an excellent article.

II. Hay saffron, cassia, and turmeric, of each 4 oz.; cardamoms 1 oz.; starch 8 oz.; precipitated chalk 2 lbs.; white sugar 4 lbs.; oil of nutmegs 2 drachms; oil of cloves 3 drachms. Reduce the dry ingredients to fine powder, and pass it through an 80 hole sieve, then add the oils, and after well mixing, pass it through a coarse sieve, (about 40 holes to the inch,) to ensure the whole being perfectly mixed.

The following form produces a powder possessing great depth and brilliancy of color.

III. Hay saffron 4 oz.; turmeric 3 oz.; powdered starch 8 oz.; precipitated chalk 2 lbs.; white sugar 4 lbs.; oils of cloves and cassia, of each 3 drachms; oil of nutmegs 2 drachms; essence of cardamoms 1 oz. *Proc.* Boil the saffron and turmeric in 1 gallon of water, placed in a bright copper pan, for 10 minutes, then, without straining, add the chalk, starch, and sugar; mix well, and continue stirring until the mixture becomes quite stiff, then break it up and dry it until fit for powdering. This must be performed in a water or steam bath. To the powder, passed through a fine sieve, as before, the oils and tincture must be added, and after being well mixed, and passed through a coarse sieve, it should be placed in a jar or bottle, and bunged up close.

Remarks. In the wholesale trade this article is kept under two forms: one in powder, as ordered by the College, and commonly called, for distinction sake, "*pulvis confectionis aromaticæ;*" the other mixed up ready for use. In preparing the latter, it is a common plan to make a strong infusion or decoction of the saffron, and to use it to mix up the other ingredients. Some persons follow the method described in the last formula, mixing up the powder to a proper consistence with water before adding the aromatics. When the price of *precipitated* chalk is an objection to its use, *prepared* chalk may be used instead. This confection is cordial, stimulant, and antacid. *Dose.* 10 to 60 grs.

CONFECTION OF BLACK PEPPER. *Syn.* Ward's Paste. *Prep.* (*Confectio Piperis Nigri*, P. L.) Black pepper and elecampane root, of each lb. j; fennel seed lb. iij; honey and white sugar, of each lb. ij; mix.

Remarks. The common practice is to keep the dry ingredients ready mixed in a bottle, and only to add the honey as wanted. The proportions are 2 parts of the latter to 7 of the mixture. The *dose* is 1 to 2 drachms 2 or 3 times a-day, in piles, fistula, &c. It should be persevered in for 2, 3, or 4 months, (Sir B. Brodie;) and as it is apt to accumulate in the bowels, its use should be accompanied by mild aperients. (Pereira.)

CONFECTIONS OF CASSIA. *Syn.* Electuarium Cassiæ, (P. L. 1788.) *Prep.* (*Confectio Cassiæ*, P. L.) Fresh cassia pulp lb. ss.; manna ℥ij; tamarind pulp ℥j; sirup of roses f℥viij. Bruise the manna and dissolve it in the sirup, then add the pulps and evaporate to a proper consistence.

CONFECTION OF HEMLOCK. (Dr. Osborne.) *Prep.* Fresh leaves of hemlock and moist sugar equal parts; beat them to a confection in a mortar.

CONFECTION OF OPIUM. *Syn.* Philonium Romanum, (P. L. 1720.) Ditto Londinense, (P. L. 1745.) Confectio Opiata, (P. L. 1788.) Ditto Opii, (P. L. 1809, and since.) *Prep.* (P. L.) Powdered opium ʒvj; long pepper ℥j; ginger ℥ij; caraways ℥iij; tragacanth ʒij; all in fine powder; sirup f℥xvj. Mix.

Use and Dose. This confection is intended as a substitute for the *mithridate* and *theriaca* of the old Pharmacopœia. It is stimulant and narcotic, and is given in flatulent colic and diarrhœa unaccompanied by fever. The dose is from 15 to 50 grs.

CONFECTION OF ORANGE PEEL. *Syn.* Conserva flavedinis Corticum Aurantiorum, (P. L. 1720 and 1745.) Ditto Corticis exterioris Aurantii Hispalensis, (P. L. 1788.) Ditto Aurantiorum, (P. L. 1824.) Ditto Aurantii, (P. L. 1809 and 1836.) *Prep.* (P. L.) The external rind of the fresh orange, separated by rasping, lb. j; white sugar lb. iij. Beat the rind in a stone mortar with a wooden pestle, then add the powdered sugar, and beat the mixture until the two are perfectly incorporated.

Remarks. This confection is tonic and stomachic, and is principally used as a vehicle for the exhibition of tonic powders.

CONFECTION OF PEPPERMINT. *Prep.* Green peppermint 4 oz.; powdered white sugar 12 oz.; beat them together as last.

Use. Anti-emetic and flatulent. Given in colic, &c., in the form of a bolus, or made into a mixture.

CONFECTION OF THE DOG ROSE. *Syn.* Confection of Hips. Conserva Fructus cynosbati, (P. L. 1720 and 1745.) Ditto Cynosbati, (P. L. 1788.) Ditto Rosæ Caninæ, (P. L. 1809, and since.) *Prep.* (P. L.) Pulp of the dog rose lb. j; powdered refined sugar ℥xx; mix by a gentle heat in an earthen vessel.

II. Pulped hips 2 cwt.; fine white sugar 2½ cwt.; incorporate them without applying heat.

Remarks. Both this and the following confection has a brighter color, if made without heat, or touching metallic vessels. On the small scale it is made by beating the ingredients together in a marble mortar, but in large quantities by grinding in a mill. It is slightly laxative, and is principally used for forming pills. It candies by keeping.

CONFECTION OF THE RED ROSE. *Syn.* Conserva Rosarum Rubrarum, (P. L. 1745.) Ditto Rosæ, (P. L. 1788.) Ditto Rosæ Gallicæ, (P. L. 1809 and 1824.) Confectio Rosæ Gallicæ, (P. L. 1836.) *Prep.* (P. L.) Petals of the red rose lb. j; refined sugar lb. iij; beat the petals in a stone mortar, then add the sugar, and again beat until thoroughly incorporated.

Remarks. On the large scale this is prepared like the confection of hips. It is astringent and tonic, and principally used for forming pills. If taken alone, the dose is 1 to 2 drachms.

CONFECTION OF RUE. *Syn.* Electuarium e Boccis Lauri, (P. L. 1720, 1745.) Confectio Rutæ, (P. L. 1809, and since.) *Prep.* (P. L.) Dried rue, caraway, and laurel berries, of each ℥iss; sagapenum (true) ℥ss; black pepper ʒij; honey ℥xvj. Reduce the dry ingredients to very fine powder, and when wanted for use, make them into a confection with the honey.

Use, &c. It is antispasmodic; in enemas 30 to

60 grs., with half a pint of gruel, for flatulent colic, &c.

CONFECTION OF SCAMMONY. *Syn.* ELECTUARIUM CARYOCOSTINUM, (P. L. 1720.) DITTO E SCAMMONIO, (P L. 1745.) DITTO SCAMMONII, (P. L. 1809 and 1788.) CONFECTIO SCAMMONEÆ, (P. L. 1809 and 1824.) *Prep.* (*Confectio Scammonii* P. L.) Scammony ℥iss; cloves and ginger, of each, ʒvj; oil of caraway f℈ss. Reduce the ingredients to a very fine powder, and when wanted for use, make them into a confection with sirup of roses, and lastly add the oil.

Use, &c. Cathartic in doses of 10 to 30 grs.

CONFECTION OF SENNA. *Syn.* LENITIVE ELECTUARY. ELECTUARIUM SENNÆ, (P. L. 1788.) CONFECTIO SENNA, (P. L. 1809, and since.) *Prep.* (P. L.) Senna ℥viij; figs lb. j; pulp of tamarinds, prunes, and cassia, of each, lb. ss.; coriander seeds ℥iv; liquorice ℥iij; sugar lb. iiss; water 3 pints. *Proc.* Rub the senna and corianders in a mortar, and separate by sifting ℥x of the mixed powders. Boil the figs and liquorice in the water, until reduced to one half; then press and strain the liquor. Evaporate the strained liquor until only 24 fluid ounces remain, then add the sugar, and when dissolved, mix in the pulps, and lastly the powder.

Use, Dose, &c. Confection of senna is a gentle and pleasant purgative, and well adapted for persons suffering from piles, and as a laxative during pregnancy. The dose is ¼ to ½ oz. taken at bedtime or early in the morning.

Remarks. Perhaps there is no one pharmacopœial preparation which it is more difficult to obtain of good quality than the above. The absolute cost of an article prepared according to the directions of the College, will be somewhere about 1*s.* 9*d.* per lb.; but there are many wholesale drug houses vending confection of senna, which they warrant as genuine, at from 9*d.* to 1*s.* a pound. Dr. Paris (in his Pharmacologia) very truly remarks, that "the directions of the Pharmacopœia are very rarely followed." I understand that considerable quantities are manufactured, into which unsound and spoiled apples enter as a principal ingredient. The following forms are, to my knowledge, employed by some members of the trade.

II. Powdered senna, pulp of tamarinds, cassia, and prunes, of each, 1½ lb.; powdered corianders ¾ lb.; Spanish juice ½ lb.; simple sirup 12 lbs.

III. As the above, omitting the cassia pulp, and adding 2 lbs. more tamarind pulp.

Both these articles are labelled P. L., and sent out as genuine, and that when no competition as to price exists. The cheaper article is made as follows:

IV. Common prunes and tamarinds, of each, 16 lbs.; treacle ¾ cwt.; species (a compound of senna dust and small senna, mixed with 3 lbs. of coriander seeds, and strengthened with jalap, all ground to a fine powder) 18¾ lbs. To this is frequently added ¼ cwt. of rotten or inferior apples, which are pulped with the prunes and tamarinds. This article is not unfrequently labelled "CONF. SENNÆ VER." by the conscientious tradesman.

CONFECTION OF SULPHUR, (COMPOUND.) *Prep.* (St. B. H.) Precipitated sulphur ℥ss; cream of tartar ʒj; honey ℥j; mix As a laxative in piles, &c. *Dose.* ℥ss.

CONFECTION OF STEEL. *Syn.* CONFECTION OF CARBONATE OF IRON. *Prep.* Confection of orange-peel and sesquioxide of iron, (P. L.,) of each, 4 oz.; powdered white sugar 6 oz.; simple sirup 2 oz.; mix. Aromatic and tonic. *Dose.* A teaspoonful to ½ oz. twice or thrice daily.

CONGELATION, (from *congelo*, to freeze.) IN CHEMISTRY. The conversion of a liquid into a solid state, by the action of cold.

The production of an extreme degree of cold is often of the utmost importance in chemical operations, and an easy method of doing so is consequently a desideratum. The means hitherto adopted for this purpose have either depended upon the sudden liquefaction of solids, or the abstraction of heat by rapid evaporation. The loss of sensible heat, by the first method, is the basis of the various processes of producing cold by what are commonly called freezing mixtures, all of which act upon the principle of liquefying solid substances without supplying heat. The caloric of liquidity being in these cases derived from that previously existing in the solid itself in a sensible state, the temperature must necessarily fall. The degree of cold produced, depends upon the quantity of heat which is thus diffused through a larger mass, or which, as it were, disappears, and this is dependent on the quantity of solid matter liquefied, and the rapidity of the liquefaction. Saline compounds are the substances most frequently employed, and those which have the greatest affinity for water, and thus liquefy the most rapidly, produce the greatest degree of cold. Thus it is, that chloride of calcium and nitrate of ammonia, when dry and in fine powder, if suddenly mixed with water, produce extreme cold. The latter, suddenly mixed with an equal weight of water at 50°, will sink the thermometer to +4°, or 28° below the freezing point. The most common and convenient freezing mixture, when snow can be procured, is formed by mixing 2 parts of that substance with 1 part of sea-salt. This will sink the thermometer to —5°, or 37° below the freezing point of water. Equal parts of these substances produce a degree of cold marked by the zero of Fahrenheit's thermometer, and is the standard taken for graduating that instrument. Mr. Walker, a gentleman who fully investigated this subject, recommends the following proportions for the production of extreme cold.

PEAU. BEZETTA CŒRULEA. *Prep.* I. Color pieces of clean linen with auvergne or ground archel, (lichen parellus.)

II. Dip pieces of clean linen into the juice of mulberries, blood-red grapes, lees of red wine, &c.

Use. To color jellies and confectionary, and the rind of cheeses.

CLARIFICATION. This word (from *clarus*, clear, and *facio*, I make) means, properly, any process of freeing a fluid from heterogeneous matter, and thus includes filtration. In its commoner sense, however, it is applied to the process of clearing liquids by the addition of some substance that either inviscates the feculous matter, and subsides with it to the bottom, or, that induces such a change in its nature or bulk, that it subsides by its own density, in each case leaving the liquor transparent. Albanum, gelatin, acids, certain salts, blood, lime, plaster of Paris, alum, heat, alcohol, &c., serve in many cases for this purpose. The first is used under the form of white of egg, for the clarification of sirups, as it combines with the liquid when cold, but on the application of heat, rapidly coagulates and rises to the surface, carrying the impurities with it, forming a scum which is easily removed with a skimmer. It is also much used for fining wines and liqueurs, particularly the red wines and more limpid cordials. Gelatin, under the form of isinglass, dissolved in water, or weak vinegar, is used to fine white wines, beer, cider, and similar liquors, that contain a sufficient quantity of either spirit or astringency (tannin) to induce its precipitation. Sulphuric acid is frequently added to weak liquors for a similar purpose, either alone, or after the addition of white of egg, or gelatin, both of which it rapidly throws down in an insoluble form. A pernicious practice exists among some unprincipled parties, of using certain salts of lead and potash to clear their liquors, especially those that are expected to sparkle in the glass, as cordial, gin, &c. For this purpose, a little sugar of lead, dissolved in water, is first mixed up with the fluid, and afterwards about half its weight of sulphate of potash, also dissolved in water, is added, and the liquor is again roused up. By standing, the sulphate of lead, formed by this mixture, subsides, and leaves the liquor clear. Blood is used in the same way as isinglass or white of eggs, for fining red wines, beer, and porter. Lime, alum, alcohol, and heat, act by curdling or coagulating the feculencies, and thus, by increasing their density, induce their subsidence. Plaster of Paris acts partly like the above, and partly like albumine, or gelatin, by enveloping and forcing down the suspended matter. Sand is often sifted over liquors for the simple purpose of acting by its gravity, but appears to be quite useless. The juices of plants are clarified by heat, which coagulates the albumine they contain. Marl, or clay, is frequently used to clear cider and perry. A strip of isinglass is generally employed to clarify coffee. (See WINES, BREWING, CORDIAL, COFFEE, INFUSION.)

CLEANING. The best way to clean a house is to *keep it clean* by a daily attention to small things, and not allow it to get into such a state of dirtiness and disorder as to require great and periodical cleanings. Some mistresses, and also some servants, seem to have an idea that a house should undergo "regular cleanings," or great washing and scrubbing matches once every three or six months, on which occasions the house is turned almost inside out, and made most uncomfortable. All this is bad economy, and indicates general slovenliness of habits. (Chambers.)

CLEAR-STARCHING. This is practised as follows: "Rinse the articles in three waters, dry them, and dip them in a thick starch, previously strained through muslin; squeeze them, shake them gently, and again hang them up to dry; and when dry, dip them twice or thrice in clear water, squeeze them, spread them on a linen cloth, roll them up in it, and let them lie an hour before ironing them. Some persons put sugar into the starch to prevent it sticking while ironing, and others stir the starch with a candle to effect the same end; we object to these practices as injurious to the article starched, or as very nauseous. The best plan to prevent sticking is to make the starch well, and to have the irons quite clean and highly polished."

CLOTH, CLEANING AND SCOURING OF. The common method of cleaning cloth is by beating and brushing, unless when very dirty, when it undergoes the operation of scouring. This is best done on the small scale, as for articles of wearing apparel, &c., by dissolving a little curd soap in water, and, after mixing it with a little ox-gall, to touch over all the spots of grease, dirt, &c., with it, and to rub them well with a stiff brush until they are removed, after which the article may be well rubbed all over with a brush or sponge dipped into some warm water, to which the previous mixture and a little more ox-gall has been added. When this has been properly done, it only remains to thoroughly rinse the article in clean water until the latter passes off uncolored, when it must be hung up to dry. For dark-colored cloths the common practice is to add some fuller's earth to the mixture of soap and gall. When *nearly* dry, the nap should be laid right, and the article carefully pressed, after which a brush, moistened with a drop or two of olive oil, should be several times passed over it, which will give it a superior finish. Cloth may also be cleaned in the dry way as follows:—First, remove the spots as above, and, when the parts have dried, strew clean damp sand over it, and beat it in with a brush, after which brush the article with a hard brush, when the sand will readily come out, and bring the dirt with it. *Black cloth* which is very rusty, should receive a coat of reviver after drying, and be hung up until the next day, when it may be pressed and finished off as before. *Scarlet cloth* requires considerable caution. After being thoroughly rinsed, it should be repeatedly passed through cold spring water, to which a tablespoonful or two of solution of tin has been added. If much faded, it should be dipped in a scarlet dye-bath. *Buff cloth* is generally cleaned by covering it with a paste made with pipe-clay and water, which, when dry, is rubbed and brushed off.

Fruit spots and similar stains may frequently be removed by holding the part over a common brimstone match, lighted, or by water acidulated with a little salt of lemons, oxalic or muriatic acid; but care must be taken not to apply this liquid to colors that it will injure.

The stains of acids may be removed by washing the part with a little spirits of hartshorn or

liquid ammonia; *those of alkalis*, by water acidulated with lemon juice or tartaric acid.

Grease spots may generally be taken out by means of a little soft soap; or, if the color be delicate, or a false dye, a little ox-gall or curd soap will be better. These must be used as above described. *Stains of painters' oils, wax, paints, or varnishes*, will not usually yield to the above plan; in these cases, a simple way is to soak the part in spirits of turpentine, and, when softened, to wash it off with the same fluid. Ether or essential oil of lemons will also quickly remove these spots, but is too expensive for general use.

CLOTH, INCOMBUSTIBLE. This is made of fibres of asbestos by weaving. It will bear a considerable heat without injury. Cotton and linen fabrics prepared with a solution of sal ammoniac, or phosphate of ammonia, may be placed in contact with ignited bodies without danger. They will carbonize, but not inflame. Solutions of alum, sea salt, &c., have been used for the same purpose. It is by a knowledge of this property of culinary salt, that jugglers are enabled to perform the common trick of burning a thread of cotton while supporting a ring or a key, without the latter falling to the ground. The cotton is reduced to a cinder, but, from the action of the salt, its fibres still retain sufficient tenacity to support a light weight.

CLOTH, RENOVATION OF. The article undergoes the process of scouring before described, and, after being well rinsed and drained, it is put on a board, and the threadbare parts rubbed with a half-worn hatter's card, filled with flocks, or with a teazle or a prickly thistle, until a nap is raised. It is next hung up to dry, the nap laid the right way with a hard brush, and finished as before. When the cloth is much faded, it is usual to give it a "dip," as it is called, or to pass it through a dye-bath, to freshen up the color.

CLOTHES, BRUSHING AND PRESERVATION OF. If very dusty, hang them on a horse or line, and beat them with a cane; then lay them on a clean board or table, and well brush them, first with a stiff brush, to remove the spots of mud and the coarsest of the dirt, and next with a softer one, to remove the dust and to lay the nap properly. If clothes be wet and spotted with dirt, dry them before brushing, and then rub out the spots with the hands. The hard brush should be used as little as possible, and then with a light hand, as it will, if roughly and constantly employed, soon render the cloth threadbare. Should there be spots of tallow-grease on the clothes, take it off with the nail, or, if that cannot be done, have a hot iron with some thick brown paper, lay the paper on the part where the grease is, then put the iron upon the spot; if the grease comes through the paper, put on another piece, till it ceases to soil it.

After the clothes are brushed, they should be hung up in a clean place, free from dust, if wanted for immediate use; but if intended to remain unused for some time, they should be placed away on the shelves of the clothes' closet or wardrobe. The latter should always be in the driest situation possible, as if the clothes be exposed to the least damp, they not only acquire an unpleasant smell, but gradually become rotten.

CLOVES. The flower buds of the eugenia caryophyllata, dried and smoked. It is a common practice to adulterate this spice in the same manner as cinchona bark. Cloves from which the oil has been distilled are dried and rubbed between the hands, previously moistened with a little sweet oil, to brighten their color, after which they are mixed up with fresh spice for sale.

COACH ACCIDENTS. "Should the horses run off, in defiance of all restraint, while you are in a coach, sit perfectly still, and in anticipation of the possible overturn, keep your legs and arms from straggling. Sit easily and compactly, so that, when upset, you will gently roll over in the direction you are thrown. We have seen ladies in these circumstances scream wildly, and throw their arms out of the windows, thus exposing themselves to the chance of broken limbs. If run away with in a gig, either sit still collectedly, or drop out at the back, so as to fall on your hands. Never jump from a rapidly-moving vehicle, unless (supposing it impossible to slip down behind) you see a precipice in front, in which case any risk of personal damage is preferable to remaining still. The Duke of Orleans lost his life by neglecting these simple precautions."

COAK. *Syn.* COKE. CHARRED COAL. MINERAL CHARCOAL. Carbonized coal. The principle of its manufacture is similar to that of charcoal. There are three varieties of coak, viz.

I. (*Kiln-made coak. Stifled coak.*) Made by burning the coal in a pile, kiln, or stove. It has a dull black color, and produces an intense heat when used as fuel. The coal is frequently burnt in a series of shallow stoves, with as little access of air as will support the combustion, and the smoke conducted through proper horizontal tunnels to a capacious brick chamber, 100 yards or more in length, kept as cool as possible by a stream of water passing over its roof, or by a shallow pond resting on it. Here the bituminous vapors are condensed in the form of tar, along with a considerable quantity of crude ammoniacal salt. Common coal yields about 3$\frac{0}{0}$ of tar when treated in this way, but some strong bituminous coal will give $\frac{1}{7}$ or $\frac{1}{8}$ of its weight. This tar, when inspissated, gives 75$\frac{0}{0}$ of pitch, and 20 to 24$\frac{0}{0}$ of a crude species of naphtha, that is excellent for out-door painting. The ammonia is made into sal ammoniac. The *screenings*, or dust-coal, separated from the better kinds of bituminous coal, is the sort commonly used for making coak in ovens.

II. (*Gas coak. Distilled coak.*) The cinder left in the retorts after the gas has been distilled off. Its color is gray, and it only produces a weak heat in burning, not sufficient to smelt iron.

III. (*Slate coak. Carbon mineral.*) From bituminous slate, burned in covered iron pots, in a similar way to that adopted for making bone-black. Also burnt in piles. It is black and friable. Used to clarify liquids, but vastly inferior to bone-black, and does not abstract the lime from sirups.

COBALT. *Syn.* REGULUS OF COBALT. A metal discovered by Brandt, in 1733. It is found in ores, associated with arsenic and other metals, and is constantly present in meteoric iron.

Prep. Dissolve oxide of cobalt in muriatic acid, and pass sulphureted hydrogen gas through the solution, until all the arsenic is thrown down; filter and boil with a little nitric acid, then add an ex-

has been so long employed in this manufacture, I am at a loss to discover; for it must be obvious that chromate of soda would answer all the purposes of chromate of potassa, the base being of little consequence, so long as it forms a soluble salt with the chromic acid, as it is merely useful as a vehicle for the chromic acid." (C. Watt, jun.)

CHROME RED. *Syn.* Dichromate of Lead. Subchromate of ditto. Red Chromate of ditto. *Prep.* I. Boil carbonate of lead with chromate of potash, in excess, until it assumes a proper color; wash well with pure water and dry in the shade.

II. Boil neutral chromate of lead with a little water of ammonia or lime water.

III. (*Process of Liebig and Wohler.*) Fuse saltpetre at a low red heat in a crucible, and throw in chrome yellow, by small portions at a time, until the nitre be nearly exhausted. A strong ebullition takes place upon each addition of the pigment, and the mass becomes black and remains so while hot. After it has settled for a minute or two, the fluid part should be poured off, and the mass remaining in the crucible washed with water, and dried by a gentle heat.

Remarks. Great care must be taken in conducting the last process, not to employ too much heat, or to allow the saline matter to stand long over the newly-formed chrome-red, as the color is thus apt to change to a brown or orange. When well managed, the product has a crystalline texture, and so beautiful a red color, that it vies with cinnabar. It has been proposed as a pigment.

CHROME YELLOW. *Syn.* Chromate of Lead. Yellow Chromate of ditto. *Prep.* I. Add a filtered solution of nitrate or acetate of lead, to a like solution of neutral chromate of potash; collect the precipitate, wash it well, and dry it out of the reach of sulphureted vapors.

II. To the lye of chromate of potash, prepared by roasting the chrome ore with nitre, and lixiviation with water, add a solution of acetate of lead, and proceed as before.

Remarks. This substance is the beautiful pigment employed by painters. Four shades are usually met with in the shops, viz.: *Pale yellow* or straw color, *yellow*, *full yellow*, and *orange*. The former are made by adding a little alum or sulphuric acid to the solution of the chromate before mixing it with the solution of lead; the latter, by the addition of a little subacetate of lead. The darker color appears to arise from a little dichromate being thrown down intimately mixed with the neutral chromate, and the paler shades from a *slight* excess of acid. I found a little alumina in some samples of pale chrome yellow, which I lately examined, and in one instance a little sulphate of lead.

CHROMIC ACID. A compound of the metal chromium and oxygen.

Prep. I. *Pure* chromic acid may be prepared by transmitting the gaseous fluoride of chromium into water contained in a vessel of platinum or silver, and evaporating the liquid to dryness.

II. By conducting gaseous fluoride of chromium into a silver or platinum vessel, the sides of which are just moistened with water, and the aperture covered with a piece of moist paper, the acid will be deposited under the form of red acicular crystals, which will fill the vessel.

III. "The principle upon which this is based is, that nitrate of baryta, which results from the decomposition of the chromate of baryta by nitric acid, is quite insoluble in concentrated nitric acid, which I have verified by many experiments, and which fact was, I believe, first observed by Mr. Reuben Phillips.

"The chromic acid may be separated from the nitrate of baryta by decantation, or, which is still better, by filtration through asbestos. Care must be taken not to let it come in contact with any organic matter, or it will be decomposed.

"The chromic acid is then to be evaporated to dryness, when the nitric acid will be volatilized, leaving pure chromic acid.

"When the quantity of chromic acid prepared by this plan is considerable, to reduce the expense as much as possible, it will be as well to carry on the evaporation so that the superabundance of nitric acid which has been used may be condensed, which may again be used for the same purpose.

"The only precautions necessary to ensure the purity of the chromic acid prepared by this plan, are the following:—to use a sufficient quantity of nitric acid, and to take care that the nitric acid is sufficiently concentrated, and that it is pure, otherwise the impurities which it contains will remain in the chromic acid.

"The chromate of baryta may be easily prepared by mixing together solutions of the chloride of barium, and any of the soluble chromates; before it is used for the preparation of pure chromic acid, it should be washed several times." (Chemist, iii. 266.)

On the commercial scale, crude chromic is prepared by either of the following plans:

IV. To a saturated solution of 100 parts of chromate of potash in water, add 49 parts of sulphuric acid, (sp. gr. 1·845.) This is the common process, but the product contains sulphate of potash.

V. Digest chromate of baryta in an equivalent proportion of sulphuric acid, diluted with water; after a few hours decant the clear liquid.

VI. Digest chromate of lead in sulphuric acid in equivalent proportions.

Mr. Charles Watt, jun., recommends chromate of lime as a source of chromic acid. This salt he prepares from the oxide of chromium, contained in the residual liquor of the process of bleaching with chromic acid, and this he effects by a very inexpensive process. The chromic solution is placed in a wooden vessel, and slaked lime cautiously added until the sulphuric or muriatic acid present is saturated, carefully avoiding excess, as oxide of chrome would be then precipitated. After an hour's repose the clear portion is decanted, and finely-slaked lime added, until all the oxide is thrown down; which may be known by the liquor becoming clear when allowed to settle. During the addition of the lime, constant agitation must be employed. The oxide of chromium must now be allowed to settle, and after the liquid portion is decanted, washed with a few pailfuls of clean water. After the latter has drained off, the residual mixture of oxide of chromium and lime must then be placed about 2 inches thick upon a large flat iron plate, set evenly over a fire, and turned every half

hour until the process be completed, which may be known by the mass assuming a yellow color, instead of the grayish one it previously possessed. Care must be taken not to employ too much heat, as the product of this process (chromate of lime) is readily decomposed, and assumes a green color, in which case it is rendered useless. From the chromate of lime the acid is procured by the action of an equivalent proportion of sulphuric acid. This process has the great recommendation of cheapness, and Mr. Watt says that he has employed it in the factory of Messrs. Haws, for nearly two years, with *perfect success.*

Prop., Uses, &c. Pure chromic acid forms red crystals, and is soluble in water and alcohol. It is readily decomposed by the action of light and contact with organic matter. Hence it should be kept in stoppered glass bottles, and its solution filtered through asbestos. The ease with which it parts with a portion of its oxygen constitutes its value as a bleaching agent. It is largely employed in the arts, in calico-printing, bleaching of textile fabrics, tallow, oils, &c.

CHROMIUM, (from χρωμα, color.) A metal discovered by Vanquelin in 1797.

Prep. I. Mix dry chloride of chromium with oil, place the paste in a crucible lined with charcoal, lute on the cover, and expose it for an hour to an intense heat. (Vauquelin.)

II. Heat the compound of terchloride of chromium and ammonia to redness, and expose it to a current of dry ammoniacal gas. (Liebig.)

Remarks. The product of the first process has a whitish-yellow color, and a metallic lustre; that of the second is a black powder. Metallic chromium has not been applied to any use in the arts.

CHROMIUM, CHLORIDE OF. *Syn.* Sesquichloride of Chromium. *Prep.* I. Dissolve the hydrated oxide in muriatic acid, and evaporate to dryness.

II. Digest chromate of lead in muriatic acid mixed with a little alcohol, and throw down the excess of lead with sulphureted hydrogen.

III. Pass dry chlorine over a mixture of chrome oxide and charcoal heated to redness, in a porcelain tube. The chloride collects as a sublimate, of a peach or purple color.

Remarks. By the first process the product is a green powder, which, when heated to 400°, becomes purplish red, and then forms pure, dry chloride of chromium. This process should be performed in a tube filled with carbonic acid gas.

CHROMIUM, OXIDE OF. *Syn.* Sesquioxide of Ditto. *Prep.* To a solution of chromate of potash, add another of protonitrate of mercury as long as any precipitate falls down. This must be well washed in water, and heated to redness in an earthen crucible.

II. Expose bichromate of potash to a strong red heat, then wash out the potassa with water.

III. Expose bichromate of potash, mixed with half its weight of sulphur, as above.

Prop. A green powder, insoluble in water. Fused with borax or glass, it imparts a beautiful green color. The emerald owes its color to this oxide. With the acids it forms salts which also have a green color. These compounds may be made by adding equal parts of muriatic acid and alcohol to a boiling solution of chromate of potassa, in water, in small portions at a time, until the red tint disappears, and the liquid assumes a green color. Pure ammonia, in excess, should now be added, when a hydrated green oxide will subside, which, after being washed with water, may be dissolved in the acids. Oxide of chrome is much used in the manufacture of colored glasses and enamels, and in dyeing.

Remarks. The above appears to be the only oxide of chromium, in opposition to the assertion of Berzelius, that there is a protoxide and deutoxide.

CHRYSAMMIC ACID. *Prep.* Add 1 part of aloes to 8 of nitric acid of sp. gr. 1·37, and heat the mixture in an open vessel. When the first violent action is over, introduce the whole into a retort, and distil to two-thirds. Then add 4 parts more of nitric acid, and keep the mixture nearly at the boiling point for some days, or as long as gas is disengaged. Water should next be added, which will throw down impure chrysammic acid, while chrysolepic acid and oxalic acid will remain in solution. The precipitate must be well washed with water combined with potash, and purified by recrystallization. The crystals are next dissolved in water, and nitric acid added, when a golden yellow powder will be deposited, which is chrysammic acid.

Prop. Soluble in alcohol, ether, and hot acids; explodes by heat, and forms salts, called chrysammates, with the bases. The salt of potash, prepared as above, is a beautiful crystalline carmine red powder, and when slowly produced it forms beautiful small greenish golden crystals. The salts of soda and magnesia are similar. Ammonia forms, with chrysammic acid, a deep purple solution, which deposites dark green crystals. The other salts of this acid are all of great beauty, and mostly of various shades of red, and exhibit a golden lustre under the polishing steel.

CIDER. *Syn.* Cyder. Pomatium. Cidre, (*Fr.*) The fermented juice of the apple. Cider and perry were known to antiquity, and are mentioned by Pliny, who calls them the wine of apples and pears. Modern Europe is, however, indebted to the Moors of Biscay, who introduced its manufacture into Normandy, whence it spread into the other provinces of France, into England, Germany, Russia, and America. The best cider made at the present day is that of Normandy, Herefordshire, and New Jersey, (U. S.,) and, next, that of Devonshire and Somersetshire. The last is, however, very inferior. Cider is made in all the temperate climates of the world, where the heat is insufficient to produce the grape, and the cold not so great as to interfere with the growth of the apple.

The process of making cider varies in different parts of England, but in every case essentially consists of—the collection of the fruit; the expression and fermentation of the juice; and the storing and management of the fermented liquor.

The apples are crushed or ground in a mill, and the pulp placed in haircloth or coarse canvass bags, and subjected to powerful pressure; the liquor which runs off is put into casks, and freely exposed to the air in the shade, and allowed to ferment. This part of the process is carefully watched, and as soon as the sediment has subsided, the liquor is racked off into clean casks. Before winter the

"The protoxide of lead, heated with chlorate of potassa in a glass tube closed at one end, gives puce oxide of lead, ($Pb\ O^2$,) mixed with a small quantity of minium. On this new reaction is founded the test which I propose with relation to the chlorates. It consists in slowly heating to fusion an intimate mixture of the chlorate and litharge in suitable proportion, covering it with a layer of chloride of sodium; in treating the fused mass with dilute nitric acid; then in collecting on a filter the puce oxide obtained, by aid of which the quantity of chlorate employed may be approximately calculated.

"This prompt and cheap process appears to me sufficiently accurate to be employed in the arts." (Comptes Rendus, xiv.)

CHLORATE OF BARYTA. (*Wheeler's process.*) Digest for a few minutes a concentrated solution of chlorate of potassa, with a slight excess of silicated hydro-fluoric acid. A precipitate of double fluoride of silicon and potassium will subside, and chloric acid remain in solution. Filter, neutralize with carbonate of baryta; again filter, when prismatic crystals of chlorate of baryta may be obtained by cautious evaporation.

Prop., &c. Soluble in 4 parts of cold water. Used to make chloric acid. This salt may also be formed by passing chlorine through a strong milk of hydrate or carbonate of baryta, in the same way as in making chlorate of potassa.

CHLORATE OF POTASSA. *Syn.* HYPEROXYMURIATE OF POTASH. OXYMURIATE OF DITTO. *Prep.* I. Transmit chlorine gas through a solution of pure potassa, or its carbonate, until the alkali be completely neutralized, then boil for a few minutes, gently evaporate until a pellicle forms on the surface, and set it aside, where it will cool very slowly. Crystals of the chlorate will form as the liquor cools, and must be collected, carefully washed with a little cold water, and purified by re-solution and crystallization. The mother liquor, by evaporation, will yield more crystals, or it may be saved for a future operation.

Remarks. This operation is best conducted in a Woolf's apparatus, or similarly arranged vessels. When the process is about half completed, as indicated by litmus paper, ceasing to be darkened, and beginning to be blanched, it is better to interrupt the operation, and to remove any chloride of potassium that may have fallen down; this may be washed with a little water, and the washings added to the liquor, when the chlorine should be again passed through the solution. When the bubbles of gas pass through without any being sensibly absorbed, the process is completed. The gas tube should be of large dimensions at the end immersed in the saline solution, and care should be taken that it does not get stopped up with crystals. In general the pure chlorate obtained from the second crystallization, amounts to about $\frac{1}{10}$ of the weight of the potash employed. The smallness of the product arises from a large portion being converted into chloride of potassium.

II. (*Graham's process.*) This consists in submitting equal equivalents of carbonate of potassa, and hydrate of lime mixed with water, to the action of chlorine, in a similar way to the above.

III. (*Liebig's process.*) *a.* The chlorine is passed into a mixture of one equivalent of chloride of potassium, and 6 equivalents of hydrate of lime, previously stirred with water to the consistence of a thin paste, whereby the lime unites with the chlorine, forming chloride of calcium, and the chloride of potassium is converted into chlorate potassa; the latter is then separated by crystallization. (Buchner's Repert.)

b. Heat chloride of lime in water until it ceases to affect vegetable colors, then dissolve it in hot water, concentrate by evaporation, and add chloride of potassium. After cooling, a quantity of crystals of chlorate of potassa are obtained. Chloride of lime, of so bad a quality as to be worthless for other purposes, may be employed; hence this is a very economical process.

IV. (*Vée's process.*) Heat a solution of chloride of lime, marking 18 or 20° Baume, in a leaden or cast-iron vessel, and when hot, dissolve therein enough chloride of potassium, to raise the hydrometer 3 or 4 degrees; then concentrate quickly, but cautiously, until the gravity of 30 or 31° Baume be obtained, and set it aside to crystallize. The mother water, concentrated to 36°, will yield more crystals. By re-solution in water, concentrating to 15 or 16°, filtering and again cooling, pure chlorate of potassa will be obtained This is a good and economical process.

V. (*Patent process of M. Romer.*) This consists in placing pure carbonate of potassa on shelves in an air-tight chamber, communicating with a retort, filled with the materials for generating chlorine, by which the alkali becomes surrounded with an atmosphere of chlorine. The operation is allowed to proceed for 12 hours without interference, after which, the heat of a water bath is applied to the retort for 6 hours longer. The apparatus is now opened, and the chlorate of potassa thus formed, is purified and freed from muriate by solution and crystallization. The materials for generating the chlorine, are—crystallized peroxide of manganese, in fine powder, 10 lbs.; plumbago 10 lbs.; common salt 30 lbs.; strongest oil of vitriol 20 lbs.; water 16 lbs.; the weight of the carbonate of potassa placed upon the shelves is 10 lbs Not being acquainted with the product obtained by this process, I cannot speak as to its value.

Prop., Uses, &c. Crystallizes in four and six sided pearly scales; dissolves in 16 parts of water at 60°, and in $2\frac{1}{2}$ parts at 212°. At about 450°, it undergoes the igneous fusion, and on increasing the heat *almost* to redness, effervescence ensues, and pure oxygen gas is given off. It yields 39·15§ by weight of this gas, (Ure,) and becomes changed into chloride of potassium. It will bear a heat of 600° Fahr. without undergoing any change. When mixed with inflammable substances, and triturated, heated, or subjected to a smart blow, it explodes with great violence. It also fulminates when thrown into strong acids. *As a medicine,* it is stimulant and diuretic. *Dose.* 5 to 15 gr. or more. It is principally used in the manufacture of fireworks, oxygen gas, lucifer matches, &c., and was formerly used to fill percussion caps, but was abandoned for fulminating mercury, as it was found to rust the nipples of the guns, which the latter does not do.

The following experiments with this salt, which are mentioned in most chemical works, may amuse the young experimentalist.—Rub 2 gr. into powder

in a mortar, add 1 gr. of sulphur, mix them well by gentle trituration, then collect the powder into a heap, and press upon it suddenly and forcibly with the pestle; a loud detonation will ensue. If the mixture be wrapped in strong paper, and struck with a hammer, the report will be still louder. 5 gr. of the salt, mixed in the same manner with $2\frac{1}{2}$ of charcoal, will be inflamed by strong trituration, especially if a grain or two of sulphur be added, but without much noise. If a little sugar be mixed with half its weight of the chlorate, and a little strong sulphuric acid poured on it, a sudden and vehement inflammation will ensue; but this experiment requires caution, as well as the following. To 1 gr. of the powdered salt in a mortar, add ½ a gr. of phosphorus; it will detonate with a loud report, on the gentlest trituration. In this experiment the hand should be defended by a glove, and great care should be taken that none of the phosphorus get into the eyes. Phosphorus may be inflamed by it under water, by putting into a wine glass 1 part of phosphorus and 2 of the chlorate, nearly filling the glass with water, and then pouring in, through a glass tube reaching to the bottom, 3 or 4 parts of sulphuric acid. This experiment, too, is very hazardous to the eyes. If olive or linseed oil be taken instead of phosphorus, it may be inflamed by similar means on the surface of the water. This salt should not be kept mixed with sulphur, or perhaps any inflammable substance, as in this state it has been known to detonate spontaneously. The addition of sulphuric acid to such mixtures immediately causes them to inflame and explode; but this experiment does not succeed with diamond powder. (Chenevix.)

Pur. The usual impurity is muriate of potash. This is readily detected by adding a few drops of a solution of nitrate of silver, which will give a curdy white precipitate soluble in liquor of ammonia, if a muriate be present, whereas the solution will remain clear, if the salt be pure. *The tests* are the same as those mentioned under chlorate. The salt may be known to contain potash, by the tests described under the article potassa, and may thus be distinguished from chlorate of soda.

CHLORATE MATCHES. *Prep.* Chlorate of potassa 30 grs.; flowers of sulphur 10 grs.; powdered lump sugar 8 grs.; powdered gum arabic 5 grs.; vermilion enough to color. *Proc.* Reduce the chlorate to fine powder in a marble or wedgewood-ware mortar, then place it on a stone slab, add the other ingredients, and mix them all together with a wooden or bone knife, adding just sufficient water to make a paste. Into this mixture the points of matches, made of slips of thin wood or pasteboard, are to be dipped, and afterwards carefully dried in a moderately warm situation.

Remarks. These matches, dipped into a little sulphuric acid, or exposed to smart friction, immediately enflame. The risk of spilling the acid may be avoided by placing a little asbestos in the bottle, and pouring thereon only as much sulphuric acid as the asbestos will absorb. It is only the composition on the match that should be touched with the acid, for if the wood be well wetted it will not burn. To ensure success it is best to dip them into melted brimstone to the height of about ⅛ of an inch before applying the composition. These matches once occupied the place that Lucifers did a few years since, and that Congreves do now.

CHLORATE, PRIMING, (FOR GUNS.) *Prep.* Pulverize the best gunpowder, and make it into a paste with water; then add half its weight of chlorate of potassa, and, while semi-fluid, drop it into the empty copper caps; place them aside in a warm situation to dry.

Remarks. The same precautions must be observed in mixing the ingredients, as directed in the last article. This priming is now superseded by fulminating mercury, which, as before observed, does not rust the nipple and foul the touchhole, like the chlorate mixture.

CHLORATES, (PER-.) Salts formed by the union of perchloric acid with the bases. The *perchlorate* of potassa may be formed by adding well-dried and finely-powdered *chlorate* of potassa, in small portions at a time, to an equal weight of concentrated oil of vitriol, gently warmed in an open vessel. The bisulphate of potassa formed must then be washed off with a *little cold water*, and the residuum of perchlorate dissolved in boiling water and crystallized. *Remarks.* These salts are distinguished from the chlorates by not turning yellow with hydrochloric acid. The other perchlorates may be formed by neutralizing the acid with the base. The *perchlorate* of potassa requires 65 times its weight of cold water for its solution, while the *chlorate* only requires 16.

CHLORIC ACID. An acid composed of chlorine and oxygen.

Prep. Dissolve chlorate of baryta in 16 times its weight of water; then add dilute sulphuric acid until all the baryta be precipitated as sulphate. The clear liquid may then be concentrated by evaporation until it acquires a thin oily consistence.

Props. In this state it has a yellowish tint, emits a smell like nitric acid, and sets fire to paper and other dry organic matter thrown into it. By heat it is resolved into chlorine and oxygen. It may be readily detected by its forming chlorate of potassa with that of alkali.

CHLORIC ACID, (PER-.) A compound of chlorine and oxygen, containing 2 eq. more of the latter than the last acid.

Prep. Put any quantity of powdered perchlorate of potassa into a retort, and pour thereon ½ its weight of strong sulphuric acid, previously diluted with an equal weight of water. Heat must now be applied, and as it rises to 284° F., vapors of this acid will pass over and condense as a colorless liquid in the receiver.

Remarks. This is a more stable compound than chloric acid, and does not inflame organic substances. By distilling it from concentrated sulphuric acid, Serullas obtained it in a solid form. In this state it hisses when thrown into water, like red-hot iron.

CHLORIDES. Compounds of chlorine with the bases in definite proportions. The tests for the chlorides are the same as for chlorine. (See CHLORINE.)

CHLORIDES OF CARBON. *Prep.* I. (*Perchloride.*) Expose the oily compound formed by mixing equal volumes of moist chlorine and olefiant gas, to the direct solar rays in a vessel full of chlorine gas. Hydrochloric acid is given off and

perchloride of carbon formed. *Props.* Solid; smells somewhat like camphor; it is twice as heavy as water, fusible, volatile; soluble in alcohol, ether, and oils, and slightly so in water; combustible.

II. (*Protochloride.*) When the perchloride of carbon is passed through a glass or porcelain tube filled with fragments of glass or rock crystal heated to redness, chlorine is separated, and a vapor formed, which must be condensed by the application of cold. This is the protochloride of carbon. *Prop.* Liquid, limpid, and colorless; vaporizes at 165° F.

CHLORINE. *Syn.* Oxymuriatic Acid. An elementary substance discovered by Scheele in 1774, and named by him dephlogisticated marine acid. It was afterwards called by the French chemists *oxygenized* and *oxymuriatic* acid, on the supposition of its being a compound of muriatic acid and oxygen. In 1809, Gay Lussac and Thernard suggested that it might be regarded as a simple substance; but it was reserved for Sir H. Davy to prove the truth of this suggestion. After some researches, in which every method of decomposing it was tried that genius and experience could suggest, he declared it to be a simple body, and gave it its present name, (from χλωρὸς, *green*,) on account of its color.

Prep. I. Mix together in a glass flask or retort strong muriatic acid with half of its weight of finely-powdered peroxide of manganese. Chlorine gas is immediately evolved even in the cold, but much more rapidly on the application of a gentle heat. *Remarks.* This gas must be collected in clean dry bottles by displacement. The tube conducting the gas must reach to the bottom of the bottle, when the chlorine, being heavier than the air, will displace the latter, without mixing with it. The bottle is known to be full by the gas overflowing the mouth, which is easily perceived by its green color. The bottle must now be closed up with an accurately-fitting stopper, previously greased, and an empty one put in its place, which must be subsequently treated in like manner. To free the gas entirely from muriatic acid, it may be passed through water; and to render it dry, it may be passed over dry chloride of calcium. Chlorine gas may also be collected over a saturated solution of common salt in the pneumatic trough.

II. Pour common muriatic acid, diluted with an equal weight of water, upon half its weight of chloride of lime, and proceed as before.

III. Pour sulphuric acid, diluted with water upon a mixture of common salt and binoxide of manganese previously placed in a retort. The proportions ordered by different authorities vary; the following are the principal:

Brand	4 water	5 acid .	3 oxide	8 salt.
Liebig	2 "	2 " .	1 "	3 "
Thernard . . .	4 "	4 " .	2 "	3 "
Graham . . .	as much dilute acid as contains	13 of oil vitriol	6 "	8 "

Remarks. The first or second process is the most convenient for small experiments in the laboratory, and the latter may be adopted where peroxide of manganese cannot be procured. The third is the cheapest method, and that employed on the large scale. Mr. Julius Seybel has lately taken out a patent for improvements in the manufacture of sulphate of soda and chlorine, which are formed by one operation. This is done by decomposing common salt by sulphuric acid, in closed vessels of lead, or lined with lead, having heat applied externally; and in employing the vapor of the muriatic acid thus formed to act on manganese immersed in water, such vapor being conducted below and permitted to escape upwards through the water and manganese.

Prop. Chlorine is a gaseous substance, possessing a yellowish green color, a pungent suffocating odor, and an astringent taste. Its most remarkable properties are, its power of destroying almost all vegetable and animal colors, and the putrid odor of decomposing organic matter; hence its value as a bleaching agent, and as a disinfectant and fumigant. Water absorbs twice its volume of this gas, and acquires a yellowish color. Under a pressure of about four atmospheres it condenses into a yellow transparent liquid. With the bases, chlorine forms an important series of compounds, called chlorides, chlorurets, or muriates, of which calomel and common salt may be taken as examples, the first being a chloride of mercury, and the second of sodium. The metallic chlorides are mostly solid at common temperatures, and all, save two, (mercury and silver,) soluble in water. They are fusible, and often crystalline. The chlorides of tin, antimony, arsenic, and mercury, are volatile and sublime unchanged. The chlorides are generally colorless, and resemble the salts in appearance. They are mostly decomposed by a strong heat. They are not decomposed by pure anhydrous sulphuric acid, but readily so by oil of vitriol. The metallic chlorides may generally be formed by the direct action of chlorine on the metals at common temperatures, and in many instances the union is accompanied by the evolution of light and heat. They may also be frequently formed by dissolving the oxides, carbonates, or hydrates of the bases, in muriatic acid, and crystallizing, or applying heat, until all the water is expelled. Chlorine has such a strong attraction for the metals that it displaces oxygen in nearly all cases at a red heat.

Tests. This gas is readily distinguished from other gases by its color, odor, and bleaching properties. It forms a white curdy precipitate with nitrate of silver, (chloride of silver,) which is insoluble in nitric acid, but readily so in liquid ammonia, and is blackened by light. Its aqueous solution dissolves gold leaf, and instantly blackens a piece of silver plunged into it. It rapidly destroys the color of iodide of starch, solution of indigo, litmus, and turmeric. The soluble chlorides may be readily detected by acidulating their solutions with nitric acid, and then adding a solution of nitrate of silver, when chloride of silver will be precipitated, and may be recognised in the way just mentioned. The insoluble chlorides may be tested by digesting them in a little liquor of potassa, when a solution of chloride of potassium will be formed, which may be treated as a liquid chloride; or the chloride may be dissolved in nitric acid, and tested with nitrate of silver as before. A simple method of detecting free chlorine is to hold a rod, dipped in

water of ammonia, over it, when white fumes of sal ammoniac will be formed; this, coupled with the property of bleaching colors, may, in most cases, be taken as evidence of the presence of this substance. (See CHLOROMETRY.)

Ant. When the fumes of chlorine are inhaled, it proves an irritative poison. The best antidotes are said to be ammoniacal gas or the vapors of warm water, of wine, or of ether. The writer of this article once suffered severely from getting a full inspiration of this gas, by the bursting of a large vessel employed in its manufacture, and which was full at the time. For a minute or two he was completely overcome; but, on being removed into the fresh air, he rapidly recovered, and, with the exception of a *violent* and *convulsive* cough, which lasted several hours, felt even better than he did before. The gas appeared to have acted both as a mental and bodily stimulant. Every known antidote was tried in this case, but without any apparent advantage. The effects gradually wore off, after the lapse of seven or eight hours.

CHLORINE, LIQUID. *Syn.* OXYMURIATIC ACID OXYMURIATIC WATER. SOLUTION OF CHLORINE. CHLORINE WATER. DEPHLOGISTICATED SPIRIT OF SALT. *Prep.* I. (*Aqua Chlorinii*, P. D.) Mix 87 parts of sulphuric acid with 124 of water, and pour it upon 100 parts of dried muriate of soda and 30 parts of oxide of manganese, previously mixed together and placed in a retort. Conduct the gas evolved into 200 parts of distilled water.

II. (*Aqua Chlorinei*, P. E.) Muriate of soda 60 grs.; red oxide of lead 350 grs.; triturate together, and put them into f℥ viij of distilled water contained in a stoppered bottle; then add 2 fluid drachms of sulphuric acid, put in the stopper, and agitate occasionally until the oxide of lead turns white. The clear liquid (after subsidence) is to be poured off into another stoppered bottle.

III. Pass chlorine gas, procured by any of the methods mentioned under Chlorine, into water, until it will absorb no more.

CHLORITES. Salts formed of the chlorous acid with the bases. The alkaline chlorites may be formed by passing a current of chlorous acid gas into a solution of the pure alkalis. They are soluble and remarkable for their bleaching and oxidizing properties.

CHLORITES, (HYPO-.) These are formed by the action of chlorine gas on the salifiable bases. Chloride of lime, soda, and potash are said by some to be hypochlorites, but this is undecided; in fact, the very existence of the hypochlorites has been denied.

CHLORO-CARBONIC ACID. *Syn.* PHOSGENE. CHLORO-CARBONOUS ACID. *Prep.* Expose equal volumes of carbonic oxide and dry chlorine to the rays of the sun, or diffused daylight. In the first case combination ensues in a few minutes, in the second after a few hours. *Prep.* A colorless gas, having a disagreeable odor; easily decomposed, especially by water.

CHLOROMETER. *Syn.* CHLORIMETER. An instrument for testing the strength of chlorides.

CHLOROMETRY. *Syn.* CHLORIMETRY. CHLORIMETRIE, (*Fr.*) The process or operation of testing the decoloring power of the compounds of chlorine. It is principally applied to those met with in commerce,—the chlorides of lime, potash, and soda. Among the numerous tests proposed for this purpose, the following appear to be those most worthy of notice.

I. (*Dalton's test.*) Weigh exactly 78 grs. of pure proto-sulphate of iron, previously dried by strong pressure between the folds of cloth, and dissolve it in 2 oz. of distilled water, to which add a few drops of muriatic or sulphuric acid. Next weigh out exactly 50 grs. of the chloride of lime, well mix it in a mortar with 2 oz. of tepid water, and pour the mixture into a graduated tube or alkalimeter. Then fill the measure up to 0 with the washings of the mortar. The whole should be now well mixed, by placing the thumb over the orifice and shaking it. The solution of chloride of lime is next to be gradually and cautiously added to the solution of sulphate of iron, until the latter be completely peroxidized, which may be known when it ceases to be affected by the red prussiate of potash. The latter test is applied by putting a drop of its solution upon a white plate, and touching it with the point of a glass stirrer or rod, dipped in the liquor under examination. As soon as the test indicates that enough of the solution of the chloride has been added, the number of measures poured from the alkalimeter must be carefully observed, from whence the richness of the sample may be estimated, as follows:—As 100 of the alkalimeter divisions contain exactly 50 grs. of the chloride, each measure will contain half a grain, and, consequently, any number of measures consumed, will represent half that number of grains of the chloride under examination; and the weight of the chloride thus used will have contained 10 grs. of chlorine—the constant quantity of that substance required to peroxide the given solution of sulphate of iron. Thus;—If 80 measures of the liquor in the alkalimeter be consumed, this quantity will have contained 40 grs. of the chloride and 10 grains of chlorine. By dividing 1000 by this number, the per centage of chlorine will be obtained, thus:

$$\frac{1000}{40}=25\%.$$

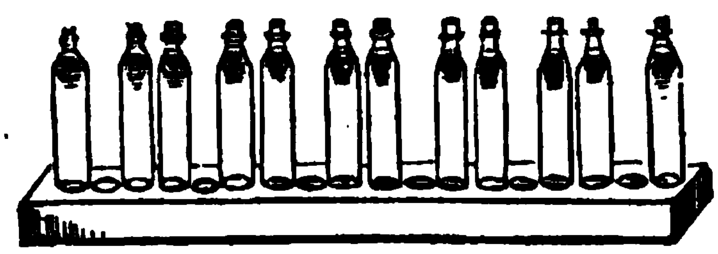
The above method admits of much greater accuracy, if the chloride of lime be dissolved in tepid water, placed in a Schuster's alkalimeter, previously weighed, and the solution made up to exactly 1000 grs. when cold. The quantity consumed may here be ascertained with great exactness. Every grain of the solution will be only equal to $\frac{1}{20}$ of a grain of the chloride. The quantity of the solution consumed is determined by weighing the alkalimeter before and after the operation. The difference is the quantity that has been used.

A modification of this plan has been suggested by Mr. Crum. He proposes to make the solution of the sulphate of iron in a stoppered bottle, and to add the chloride in the state of powder from a weighed quantity.

II. (*Crum's process.*) Mix equal weights of water and muriatic acid, and dissolve therein cast-iron borings until saturated. To ensure perfect saturation a large excess of iron is employed, and the liquid kept at the heat of boiling water for some time. One measure of the solution, marking 40° on Twaddle's scale, (sp. gr. 1·200,) is mixed with an equal quantity of acetic acid, (sp. gr. 1·048.)

This forms the proof solution, which, if mixed with 6 or 8 parts of water, is quite colorless, but chloride of lime occasions the production of peracetate of iron, which gives it a red color.

The above proof-solution is then poured into 12 two-oz. vials, of exactly equal diameters, to the amount of $\frac{1}{5}$ of their capacity; these are filled up with bleaching liquid of various strengths; the first at $\frac{1}{12}$ of a degree of Twaddle, the second $\frac{2}{12}$, and so on up to $\frac{12}{12}$ or 1°. They are then well corked up, and, after agitation, arranged side by side on a tray, furnished with holes to receive them, in the manner represented in the engraving. A se-



ries of test vials are thus formed, showing the various shades of color that the solutions of the given strengths are capable of producing. To ascertain the strength of an unknown sample of bleaching liquor, the proof solution of iron is put into a vial, exactly similar to the 12 previously used, and in precisely the same proportion, ($\frac{1}{5}$.) The vial is then filled up with the bleaching liquor, well shaken, and placed beside that one of the 12 already prepared which it most resembles in color. The number on that vial expresses the strength of the sample under examination, in $\frac{1}{12}$ths of a degree of Twaddle's hydrometer.

Table exhibiting the quantity of Bleaching Liquid, at 6° on Twaddle's scale, (sp. gr. 1·030,) required to be added to a weaker liquor, to raise it to the given strengths. Adapted from Mr. Crum's table by Mr. Cooley.

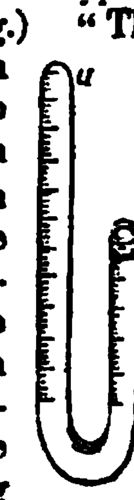
Strength of sample in $\frac{1}{12}$°.	Required Strength.	Proportions required. Given Sample.	Liquor at 6°.
		Parts.	Part.
Water.	$\frac{8}{12}$°	8	1
1	do.	$9\frac{1}{8}$	1
2	do.	11	1
3	do.	$13\frac{1}{3}$	1
4	do.	17	1
5	do.	23	1
6	do.	35	1
7	do.	71	1
Water.	$\frac{6}{12}$°	11	1
1	do.	$13\frac{1}{3}$	1
2	do.	17	1
3	do.	23	1
4	do.	35	1
5	do.	71	1
Water.	$\frac{4}{12}$°	17	1
1	do.	23	1
2	do.	35	1
3	do.	71	1
Water.	$\frac{3}{12}$°	23	1
1	do.	35	1
2	do.	71	1

Remarks. The preceding method is admirably suited for weak solutions, such as are employed for bleaching textile fabrics, and is well adapted (from its simplicity) to the purposes of practical men. It is employed in many of the Scotch bleaching houses.

According to Mr. Crum, the range of strength within which cotton is safe, is very limited. A solution at 1° of Twaddle's scale, (sp. gr. 1·005,) is not more than safe, while one at $\frac{1}{2}$° is scarcely sufficiently strong for the first operation on stout cloth, unless it be packed more loosely than usual. (Trans. Glasgow Phil. Soc.)

III. (*Ure's test.*) This consists in adding water of ammonia of a known strength, tinged with litmus, to a solution of a given weight of the chloride, until the whole of the chlorine be neutralized, which is known by the color ceasing to be destroyed. From the quantity of ammonia consumed, the strength is estimated. During the above process azote is evolved, and the estimation of the volume thus liberated has been proposed as another easy method of chlorimetry by Dr. Ure.

This gentleman recommends the two substances to be mixed in an inverted and graduated syphon tube over mercury. (See Engraving.) "The shut end *a* and the open end *b*, are both graduated to one scale; for example, to $\frac{1}{100}$ of an inch, or to grain or 10 grain measures. The tube is to be filled with mercury, and then 10 measures of it are to be displaced at the open end, by inserting a wooden plug. This space being filled with a solution of a given weight of chloride of lime, is to be turned up into the shut end, by covering the open end with the finger and inverting the tube; a few drops of water may be sent through to wash the mercury. The ammonia being now let up will cause a reaction, and evolve a quantity of azote, equivalent to the chlorine present. The action may be accelerated by holding the sealed end of the tube over the flame of a spirit-lamp. The mercury is protected from the chlorine by the ammonia; and should any notion be entertained of such an action, the ammonia may be let up first. I have made innumerable researches over mercury, with a detached apparatus of this kind, which combines precision with rapidity of result." (Ure's Dict. Arts.)



IV. (*Process of M. Gay Lussac.*) One part of the best indigo is dissolved in 9 parts of strong sulphuric acid, by the aid of a gentle heat. This solution is then mixed with distilled water, in such proportion, that 1 volume of chlorine gas shall exactly decolor 10 volumes of this solution. Each measure so decolored is called a degree, and each degree is divided into fifths. 5 grains of the best chloride of lime, dissolved in 500 grain measures of water, will possess the above power, and indicate 10° or proof, and will decolor 10 times its volume of the indigo solution. The objections to this method of chlorimetry are, that the indigo solution alters by keeping, and that it is not adapted for testing strong solutions of chloride of lime. "I have tried the indigo test in many ways, but never could confide in it." (Ure.)

CHLORO-NITROUS GAS. A gaseous compound, discovered by E. Davy. It is obtained

by treating fused chloride of sodium, potassium, or calcium, in powder, with as much strong nitric acid as is sufficient to wet it, when this gas is evolved. *Prop.* It has an orange color, smells like chlorine, and bleaches. Soluble in water.

CHLOROPHYLL. *Syn.* CHLOROPHILE. CHLOROPHYLE. The green coloring matter contained in the leaves, stalks, unripe fruit, and juices of most plants. It is extracted by ether, and purified by successive solutions in alcohol and muriatic acid; from the last it is precipitated pure by water.

Prop. A dark green mass, producing a grass-green powder. It is soluble in ether, alcohol, acids, alkalis, and oils. If an earthy or metallic salt be mixed with the alcoholic solution, and an alkaline carbonate be added, the earth or oxide is thrown down in combination with this coloring matter, forming a green lake, possessing considerable permanency. Pelletier and Caventou, who first discovered chlorophyll, obtained it by simply pressing the leaves, washing in water, and afterwards treating it with alcohol.

CHLOROUS ACID. *Syn.* PEROXIDE OF CHLORINE. A compound of oxygen and chlorine. *Prep.* Chlorate of potassa in fine powder, made into a paste with strong sulphuric acid, is put into a retort and heated in a water-bath, hot but not boiling. A yellowish green gas is given off, which may either be collected in dry bottles, or passed into water, when it will form liquid chlorous acid.

Props., &c. Its aqueous solution undergoes gradual decomposition, yielding chlorine and chloric acid. It possesses powerful oxidizing and bleaching properties, and unites with the bases forming salts called chlorites. These are all soluble in water, and possess bleaching powers like the acid. They may be recognised by the evolution of chlorous acid gas when acted on by an acid.

CHOCOLATE. *Syn.* CHOCOLADA. CHOCOLAT, (*Fr.*) The roasted cacao nut made into a paste by triturating it in a heated mortar, with sugar and aromatics, and cast in tin moulds, in which it concretes into cakes on cooling. The term is derived from two Indian words, *choco*, sound, and *atte*, water; because of the noise made in its preparation. (Dr. Alston.)

Qual. Chocolate is nutritive and wholesome, if taken in moderation, but is sometimes apt to disagree with weak stomachs, especially those that are easily affected by oily substances or vegetable food. The quantity of aromatics mixed with the richer varieties, improve the flavor, but render them more stimulant and prone to produce nervous symptoms, and complaints of the head.

Prep. The nuts are first roasted, (on the small scale this may be done in a frying-pan,) and after being cleared from the husks, reduced to coarse powder; they are then beaten in an iron mortar, the bottom of which is heated, until they are reduced to a paste, which is effected by the action of the heat on the oil or butter they contain. This paste or semi-fluid mass is then poured out into moulds, and left until cold, when it forms *cake chocolate*, or *chocolate paste;* or it may be reduced to coarse powder, by grinding, when it is known under the name of *chocolate powder*.

Remarks. Chocolate, prepared as above, without the addition of aromatics, is known in the trade as *plain chocolate*. The Spaniards flavor it with vanilla, cloves, and cinnamon, and frequently scent it with musk and ambergris. In general, they add too large a quantity of the last four articles. The Parisians, on the contrary, use but little flavoring, and that principally vanilla. They employ the best caracca nuts, and add a considerable quantity of refined sugar.

The mass of the common chocolate sold in England, is prepared from the cake left after the expression of the oil, and this is frequently mixed with the roasted seeds of ground peas, and maize or potato flour, to which a sufficient quantity of inferior brown sugar, or treacle and mutton suet is added, to make it adhere together. In this way is made the article commonly marked in the shops at 8*d.*, 9*d.*, and 10*d.* the pound. I know a person who lately bought a large quantity at 5*d.*, whereas good nuts, in their unprepared state, cost at wholesale more than double the money.

To excel in the manufacture of chocolate requires some little experience. The roasting of the nuts must be done with great care, and the process stopped as soon as the aroma is well developed. They should then be turned out, cooled, and fanned from the husks. On the large scale, chocolate is made in mills, worked by steam power, and the machinery employed in the grinding, admirably fulfils its duty.

The South American beans are esteemed the best for making chocolate. Like wine, it improves by age, if kept in a dry but not too warm a place.

CHOCOLATE CREAM. *Prep.* Chocolate scraped fine 1 oz.; thick cream 1 quart; sugar (best) 6 oz.; heat it nearly to boiling, then remove it from the fire, and mill it well. When cold, add the whites of 8 or 10 eggs; whisk rapidly, and take up the froth on a sieve; serve the cream in glasses, and pile up the froth on the top of them.

CHOCOLATE DROPS. Reduce 1 oz. of chocolate to fine powder by scraping, and add it to 1 lb. of finely-powdered sugar; moisten the paste with clear water, and heat it over the fire until it runs smooth, and will not spread too much when dropped out; then drop it regularly on a smooth plate. Avoid heating it a second time.

CHOCOLATE FOR ICING. *Syn.* SORBET AU CHOCOLAT. *Prep.* Rub 2 oz. of chocolate to a paste with 2 tablespoonfuls of hot milk, then add cream for icing 1 quart. Ice as wanted for use.

CHOCOLATE FOR THE TABLE. *Prep.* Put the milk and water on to boil; then scrape the chocolate fine, from one to two squares to a pint, to suit the stomach: when the milk and water boils, take it off the fire, throw in the chocolate, mill it well, and serve it up with the froth, which process will not take five minutes. The sugar may either be put in with the scraped chocolate, or added afterwards.

It should never be made before it is wanted; because heating again injures the flavor, destroys the froth, and separates the body of the chocolate; the oil of the nut being observed, after a few minutes' boiling, or even standing long by the fire, to rise to the top, which is the only cause why chocolate can offend the most delicate stomach.

CHOCOLATE, FRENCH. *Prep.* Finest ca-

timate their power, and consequently, generally add too much of them, and thus not only is the liquor rendered disagreeably high flavored, but the quantity of oil present turns it '*milky*,' or '*foul*,' on the addition of the water. This again is another source of annoyance, as from the consistence or viscidity of the fluid, it is less readily '*fined down*' than unsweetened liquor, and often gives much trouble to clumsy and inexperienced operators. The most certain way to prevent this is to use *too little*, rather than *too much* flavoring; for if the quantity prove insufficient, it may readily be '*brought up*,' even after the cordial is made.

A careful attention to the previous remarks will render this branch of the rectifier's art far more perfect and easy of performance than it is at present, and will, in most cases, produce at *once* a satisfactory article, '*fine*, *sweet*, and *pleasant*.'

It may be observed, before concluding this short notice, that the majority of cordials may be made with the pure essential oils, of *nearly* equal flavor to those prepared by distillation; and for such as *are colored*, simple digestion of the ingredients is almost universally employed. Inferior lump, or even good brown sugar is used for some dark and strong-flavored articles. Ingredients that are *not volatile*, are, of course, always added after distillation. Though I have said that very excellent cordials may be made *without* distillation, yet the *still* should be always employed to impart the flavor and aroma of volatile aromatics to spirits, when the expense, labor, and time are of no importance compared to the production of a superior article. The strength at which cordials are usually sent out by permits is 60 or 64 u. p.

CORDIAL, ANISEED. *Prep.* I. Aniseed (bruised) 1 lb.; proof spirit 6 gallons; macerate for a week; then distil 5 gallons; add 2 gallons of clear soft water, and 1 gallon of clarified sirup. This will make 8 gallons of cordial 24 u. p., which is as weak as "aniseed" should ever be made. It may be reduced by sweetened water.

II. Instead of distilling off the spirit, merely pass it through a wine-bag, to take off the seed, lower it with clear soft water, and sweeten as before.

III. Instead of 1 lb. of aniseed, add enough of the essential oil, dissolved in spirit of wine, to produce the desired flavor; 2 drachms of the oil is fully equal to 1 lb. of the seeds.

CORDIAL, BILIOUS, (CHAMBERLAIN'S.) An American medicine, prepared from the inner bark of the juglans cinerea, mixed with spices.

CORDIAL FOR CALVES. *Prep.* I. Caraways, powdered, ½ oz.; ginger and carbonate of soda, of each a spoonful; gin or brandy, ¼ of a wineglassful; water 6 oz.

II. Brandy ½ oz.; cow's urine 4 oz.; mix. (Gray.)

Use. As a stimulant for looseness, &c., in calves.

CORDIAL, CARAWAY. *Prep.* Bruised caraway seeds 3 lbs., or, essential oil of caraway 1½ oz.; sugar 56 lbs.; clean spirit, at proof, 40 gallons; water q. s.

Remarks. The addition of 30 drops of oil of cassia, and 20 drops each of essence of lemon and orange-peel, to the above quantity, improves the flavor; also a larger quantity of sugar must used, if the cordial is to be much lowered.

II. Seeds ¼ lb., or oil 1 drachm; proof spi[rit] gallon; sugar 3 lbs.; water q. s. As last.

CORDIAL, CEDRAT. *Prep.* I. Essence cedrat ¼ oz.; dissolve in pure proof spirit 1 ga[llon] add water 3 pints, agitate well; draw off 3 q[uarts] and add an equal measure of clarified sirup.

Remarks. This is a most delicious cordial.

II. Cut 12 lemons in pieces, and digest in [spirit] of wine 1 gallon; add water 1 quart; draw [off 1] gallon, and add an equal weight of capillaire. [In]ferior to the last.

CORDIAL, CINNAMON. This is sel[dom] made with cinnamon, but with either the ess[ential] oil, or bark of cassia. It is preferred colored, [and] therefore may be very well prepared by simp[le di]gestion. If the oil be used, 1 dr. will be fou[nd to] be enough for 2 or 3 gallons of spirit. The a[ddi]tion of 2 or 3 drops each of essence of lemon [and] orange peel, with about a spoonful of essen[ce of] cardamoms to each gallon, will improve it. S[ome] persons add to the above quantity 1 drach[m of] cardamom seeds and 1 oz. each of dried or[ange] and lemon peel. 1 oz. of oil of cassia is consi[dered] to be equal to 8 lbs. of the buds, or bark. [If] wanted dark it may be colored with burnt s[ugar.] The quantity of sugar is 1½ lb. to the gallon.

CORDIAL, CITRON. *Prep.* Yellow rin[ds of] citrons 3 lbs.: orange peel 1 lb.; nutmegs br[uised] 2 oz.; proof spirit 13 gallons; distil .. nace, add water sufficient, and 2 lbs. of fine lump s[ugar] for every gallon of the cordial.

CORDIAL, CLOVE. *Prep.* Bruised cl[oves] 1 oz., or essential oil, 1 dr. to every 4 gallo[ns of] proof spirit. If distilled it should be drawn [off] with a pretty quick fire. It is preferred of a [very] deep color, and is therefore strongly colored [with] poppy-flowers or cochineal, or more comm[only] with brandy coloring, or red sanders wood. [It] should have 3 lbs. of sugar to the gallon, and [this] need not be very fine. The addition of 1 drac[hm] of bruised pimento, or 5 drops of the oil for e[very] ounce of cloves, improves this cordial.

CORDIAL, CORIANDER. *Prep.* 1 lb. coriander seeds; 1 oz. of caraways, and the p[eel] and juice of 1 orange to every 3 gallons of p[roof] spirit.

CORDIAL, GOLD. *Prep.* Angelica r[oot] sliced, 1 lb.; raisins ½ lb.; coriander seeds 2 o[z.;] caraway seeds and cassia, of each 1½ oz.; clo[ves] ½ oz.; figs and sliced liquorice root, of each 4 o[z.;] proof spirit 3 gallons; water 1 gallon. Dig[est 2] days, and draw off 3 gallons by a gentle heat; [to] this add 8 lbs. of sugar dissolved in 1 quart e[ach] of rose-water and clear soft water, and steep [1] oz. of hay saffron in the liquid until it acquir[es a] proper color.

Remarks. The above is the form for a cord[ial] once in much esteem, and which derived its na[me] from a small quantity of gold leaf being added to [it.] It is now but little drunk, and this addition seld[om] made.

CORDIAL, GODFREY'S. *Prep.* I. M[o]lasses 15 lbs.; distilled water 2¾ gallons; dissolv[e,] add oil of sassafras 1 oz. dissolved in rectified sp[irit] of wine ½ gallon, bruised ginger ¾ oz.; cloves ½ o[z.;] laudanum 8 oz.; macerate for 14 days, and st[rain] through flannel.

stance, so long as carbonaceous matters from the fire are entirely excluded, and the required temperature is attainable. Unless strong heat is employed, no decomposition will take place; the temperature already employed in manufacturing this article from the nitrates, will be sufficient, and the furnaces used in every way suitable. The mass should be well raked about every half hour, to ensure the whole of it being sufficiently heated.

"Proceeding thus, the manufacturer may ascertain whether the process is complete by taking out a sample from the furnace, and treating it with a slight preponderance of dilute pure nitric acid, then adding chloride of barium; if, on this addition, much precipitate of sulphate is formed, the operation is not completed; but if, on the other hand, only a slight milkiness is produced, the 'batch' may be considered as finished.

"I have found, from numerous analyses, that different samples of the ore vary considerably in the quantity of oxide of chromium which they contain, and I therefore advise every manufacturer to analyze a fair average sample before he makes a purchase."

The following is the plan which Mr. Watt has adopted for this purpose:—

"Take a given weight of the ore, say 200 gr., previously reduced to a fine powder, and intimately mix it with twice its weight of the nitrate of potassa or soda,* adding a little slaked lime to prevent it from fluxing; place it in an iron crucible, and subject it to a strong red heat for about 3 or 4 hours; then treat the mass with water to dissolve out the chromate. The insoluble matter having been washed several times until the water has ceased to come off colored, the washings are to be added together and evaporated to concentrate the solution. This being done, it is to be treated with an excess of dilute sulphuric acid to liberate the chromic acid, and then treated with spirit of wine, by which the chromic acid will be reduced to the state of green oxide, which will remain in solution in the preponderance of sulphuric acid employed. A solution of caustic ammonia in excess is then to be added, which will precipitate the oxide of chromium; the mass is then boiled to evaporate the superabundance of ammonia.

"It must now be passed through a filter to collect the oxide, and a little fresh water poured on it to free it from any saline matter: then gently dry on the filter, when it may be entirely removed with ease, as the oxide, which was previously of a very bulky nature, contracts very considerably. It may then be subjected to a dull red heat in a silver, platinum, or porcelain crucible, and afterwards its weight ascertained, from which the per centage of oxide of chromium which the ore contains, and, consequently, the amount of sulphate required to convert it into a chromate, may be calculated." (Chemist, iv. 70.)

Prop., Uses, &c. The commercial chromate of potash has a bright yellow color, but in other respects, resembles coarse culinary salt. It is used in various processes in the arts,—in dyeing, bleaching, the manufacture of chromic acid, bichromate of potassa, and several other chromates.

* "It will be as well to use a nitrate in the analysis; the quantity being small, it will be of no consequence."

Pur. Chromate of potash is very commonly adulterated with sulphate and muriate of potash, it therefore becomes important to the manufacturer to be able to test its purity.

I. (*Test of M. Zuber.*) Add tartaric acid, dissolved in 50 parts of water, to a like solution of the sample. As soon as the decomposition is complete, and the color verges towards the green, the supernatant liquor should afford no precipitate with either the nitrate of silver or baryta, whence the absence of muriates and sulphates may be inferred. The proportions are, 8 parts of tartaric acid to 1 part of the chromate, both in solution. If saltpetre be the adulterating ingredient, the sample will deflagrate when thrown upon burning coals.

Mr. Watt says, "A short time ago, I was supplied with a sample which was nothing but sulphate of soda and chloride of sodium, colored with a strong solution of the chromate, and which caused a white precipitate in any of the soluble salts of lead. For the benefit of the purchaser, I subjoin the following method of examining the chromates of potassa and soda.

"First ascertain the quantity of moisture contained in the sample, by weighing out a certain portion, drying it on a sand-bath, and again weighing; the loss of weight will give the quantity of water: then dissolve it in distilled water, and add any soluble salt of lead until it ceases to give a precipitate. The mass is then to be boiled, and more distilled water added; the supernatant liquor is then to be poured off, and if the sample under examination contain any chloride of sodium, small shining crystalline needles of chloride of lead will form in the liquor as it cools. The remaining precipitate is then to be treated with strong nitric acid, which will decompose the chromate; by adding distilled water, the nitrate of lead, formed by the decomposition of the chromate of lead, will be dissolved, and the remaining sulphate of lead, if any, may be dried, and its amount ascertained, from which the quantity of sulphate in the chromate may be calculated.

"If it be required to ascertain the quantity of chloride, this may be done by redissolving the chloride of lead by means of heat, and operating on it by any of the soluble salts of silver." (Chemist, iii. 388.

CHROMATE OF POTASH, (BI- OR SUPER-.) *Prep.* Acidulate a concentrated solution of the neutral chromate with sulphuric, or, still better, the acetic acid. Then heat the liquid and allow it to cool slowly, when beautiful red crystals of bichromate of potash will be deposited. Its *Prop., Uses, and Tests* are the same as the neutral salt.

CHROMATE OF POTASH, SOLUTION OF. *Prep.* Dissolve neutral chromate of potash 1 oz., in distilled water 1 lb. *Use.* As a test liquor for metals, especially lead.

CHROMATE OF SODA. This salt may be prepared in the same way as chromate of potash, by employing a salt of soda instead of potassa in the preceding processes. It may also be made on the small scale for experiment, by neutralizing chromic acid with carbonate of soda.

Remarks. This salt has been proposed as a substitute for chromate of potassa, and has the advantage in cheapness. "Why nitrate of *potassa*

CORNS. Round, horny, cutaneous extuberances, with central nuclei, very sensitive at the base, arising from continued pressure over the projection of the bones, from *tight* or stiff shoes or boots. Corns are of two kinds, hard and soft. The former grow on the exposed portions of the joints, the latter between the toes.

Treat. First soak the feet in warm water for a few minutes, then pare the corns as close as possible with a sharp knife, taking care not to make them bleed. They may now be touched over with a little lunar caustic, or nitric acid. The former is used by merely rubbing it on the corns; previously *slightly moistened* with water; the latter by moistening them with it, by means of a strip of wood, or preferably a rod of glass. This treatment adopted every other day for 10 or 12 days, accompanied by the use of *soft, loose shoes*, will generally effect a cure. Concentrated acetic acid may be used instead of nitric acid, and is preferred by some persons from not staining the skin, but it is less active, and requires to be more frequently applied. It has been recommended to remove large corns by ligatures of silk, applied as close to the base as possible, and tightened daily until they drop off; but this plan is tedious, and is not always successful. Another mode of extirpation is the application of a small blister, which will frequently raise them with the skin out of their beds. In this case the exposed surface must be dressed with a little simple ointment. Soft corns may also be easily removed by applying ivy leaf previously soaked in strong vinegar, changing the piece every morning; or by placing a dressing of soap cerate, spread on a bit of lint or old rag, between the toes. One of the simplest and best remedies for hard corns, and which has lately received the sanction of high medical authority, is to wear upon the toe or part affected a small circular pi of soft leather, or still better, a piece of amad spread with diachylon or other emollient pla and having a hole cut in its centre the size of corn. (Sir B. Brodie.) By this means the pres of the boot or shoe is equalized, and the corn p tected.

Prevention. This consists in keeping the f clean, by frequent ablutions with warm water, the use of *easy, soft shoes or boots.* Without latter precaution, corns will generally return, e after they appear to have been perfectly remo

CORNS, POPULAR REMEDIES FOR. (*Lotion.*) Sal ammoniac 1 oz., spirit 4 oz.; diss Moisten the corn with this lotion every morn and evening.

II. (*Powder.*) Savine leaves 2 oz.; verdig oz.; red precipitate ½ oz.; all in powder. Mix. A plied by means of a piece of rag to the corn nigh

III. (*Plaster.*) White diachylon and ye rosin, of each 2 oz.; melt and add finely-powd verdigris 1 oz. For use, spread it on paper, li or leather, and apply a small piece to the corn.

CORN SOLVENT, SIR H. DAVY'S. P Potash 2 parts, salt sorrel 1 part; each in powder. Mix and lay a small quantity on corn for four or five successive nights, binding it with a rag.

CORRECTING PROOFS. (In Typogra The operation of marking on the proof sheets o work any errors of orthography, punctuation, rangement, or language, they may contain, also any alterations that may appear necess The following specimen will explain the meth generally adopted for this purpose, and with a li attention will enable any person to superintend work through the press, as far, at least, as pends upon the correction of the proofs:

hour until the process be completed, which may be known by the mass assuming a yellow color, instead of the grayish one it previously possessed. Care must be taken not to employ too much heat, as the product of this process (chromate of lime) is readily decomposed, and assumes a green color, in which case it is rendered useless. From the chromate of lime the acid is procured by the action of an equivalent proportion of sulphuric acid. This process has the great recommendation of cheapness, and Mr. Watt says that he has employed it in the factory of Messrs. Haws, for nearly two years, with *perfect success.*

Prop., Uses, &c. Pure chromic acid forms red crystals, and is soluble in water and alcohol. It is readily decomposed by the action of light and contact with organic matter. Hence it should be kept in stoppered glass bottles, and its solution filtered through asbestos. The ease with which it parts with a portion of its oxygen constitutes its value as a bleaching agent. It is largely employed in the arts, in calico-printing, bleaching of textile fabrics, tallow, oils, &c.

CHROMIUM, (from χρωμα, color.) A metal discovered by Vauquelin in 1797.

Prep. I. Mix dry chloride of chromium with oil, place the paste in a crucible lined with charcoal, lute on the cover, and expose it for an hour to an intense heat. (Vauquelin.)

II. Heat the compound of terchloride of chromium and ammonia to redness, and expose it to a current of dry ammoniacal gas. (Liebig.)

Remarks. The product of the first process has a whitish-yellow color, and a metallic lustre; that of the second is a black powder. Metallic chromium has not been applied to any use in the arts.

CHROMIUM, CHLORIDE OF. *Syn.* Sesquichloride of Chromium. *Prep.* I. Dissolve the hydrated oxide in muriatic acid, and evaporate to dryness.

II. Digest chromate of lead in muriatic acid mixed with a little alcohol, and throw down the excess of lead with sulphureted hydrogen.

III. Pass dry chlorine over a mixture of chrome oxide and charcoal heated to redness, in a porcelain tube. The chloride collects as a sublimate, of a peach or purple color.

Remarks. By the first process the product is a green powder, which, when heated to 400°, becomes purplish red, and then forms pure, dry chloride of chromium. This process should be performed in a tube filled with carbonic acid gas.

CHROMIUM, OXIDE OF. *Syn.* Sesquioxide of Ditto. *Prep.* To a solution of chromate of potash, add another of protonitrate of mercury as long as any precipitate falls down. This must be well washed in water, and heated to redness in an earthen crucible.

II. Expose bichromate of potash to a strong red heat, then wash out the potassa with water.

III. Expose bichromate of potash, mixed with half its weight of sulphur, as above.

Prop. A green powder, insoluble in water. Fused with borax or glass, it imparts a beautiful green color. The emerald owes its color to this oxide. With the acids it forms salts which also have a green color. These compounds may be made by adding equal parts of muriatic acid and alcohol to a boiling solution of chromate of potassa, in water, in small portions at a time, until the red tint disappears, and the liquid assumes a green color. Pure ammonia, in excess, should now be added, when a hydrated green oxide will subside, which, after being washed with water, may be dissolved in the acids. Oxide of chrome is much used in the manufacture of colored glasses and enamels, and in dyeing.

Remarks. The above appears to be the only oxide of chromium, in opposition to the assertion of Berzelius, that there is a protoxide and deutoxide.

CHRYSAMMIC ACID. *Prep.* Add 1 part of aloes to 8 of nitric acid of sp. gr. 1·37, and heat the mixture in an open vessel. When the first violent action is over, introduce the whole into a retort, and distil to two-thirds. Then add 4 parts more of nitric acid, and keep the mixture nearly at the boiling point for some days, or as long as gas is disengaged. Water should next be added, which will throw down impure chrysammic acid, while chrysolepic acid and oxalic acid will remain in solution. The precipitate must be well washed with water combined with potash, and purified by recrystallization. The crystals are next dissolved in water, and nitric acid added, when a golden yellow powder will be deposited, which is chrysammic acid.

Prop. Soluble in alcohol, ether, and hot acids; explodes by heat, and forms salts, called chrysammates, with the bases. The salt of potash, prepared as above, is a beautiful crystalline carmine red powder, and when slowly produced it forms beautiful small greenish golden crystals. The salts of soda and magnesia are similar. Ammonia forms, with chrysammic acid, a deep purple solution, which deposites dark green crystals. The other salts of this acid are all of great beauty, and mostly of various shades of red, and exhibit a golden lustre under the polishing steel.

CIDER. *Syn.* Cyder. Pomatium. Cidre, (*Fr.*) The fermented juice of the apple. Cider and perry were known to antiquity, and are mentioned by Pliny, who calls them the wine of apples and pears. Modern Europe is, however, indebted to the Moors of Biscay, who introduced its manufacture into Normandy, whence it spread into the other provinces of France, into England, Germany, Russia, and America. The best cider made at the present day is that of Normandy, Herefordshire, and New Jersey, (U. S.,) and, next, that of Devonshire and Somersetshire. The last is, however, very inferior. Cider is made in all the temperate climates of the world, where the heat is insufficient to produce the grape, and the cold not so great as to interfere with the growth of the apple.

The process of making cider varies in different parts of England, but in every case essentially consists of—the collection of the fruit; the expression and fermentation of the juice; and the storing and management of the fermented liquor.

The apples are crushed or ground in a mill, and the pulp placed in haircloth or coarse canvass bags, and subjected to powerful pressure; the liquor which runs off is put into casks, and freely exposed to the air in the shade, and allowed to ferment. This part of the process is carefully watched, and as soon as the sediment has subsided, the liquor is racked off into clean casks. Before winter the

CORROSION, PREVENTION OF. The best means of preventing the corrosion of metals is first to dip the articles into very dilute nitric acid, and afterwards to immerse them in linseed oil, allowing the superfluity of oil to drain off; they are by this means very effectively preserved from rust or oxidation. (W. J. Lander.)

COSMETICS. (*Cosmetica*, from Κοσμέω, *I adorn.*) Any external application used for the purpose of preserving or restoring the beauty. The term is generally understood to refer to substances applied to the cuticle, to improve the color and clearness of the complexion; but some writers have included under this head, every topical application to promote the personal appearance. Hence cosmetics may be divided into three kinds, viz.:—*Cutaneous cosmetics*, or those applied to the skin; *hair cosmetics*, or such as are employed to promote the growth and beauty of the hair; and *teeth cosmetics*, or such as are used to cleanse and beautify the teeth. The present article will be confined to a short notice of the first of these divisions, referring the reader to the separate heads —*hair dyes, pomatums, pommades, depilatories, dentifrices, tooth powders, &c.*, for information respecting the remainder.

CUTANEOUS COSMETICS. The most simple and universally employed cosmetics are soap and water, which at once cleanse and soften the skin. Soap containing a full proportion of alkali, exercises a solvent power upon the cuticle, a minute portion of which it dissolves; but when it contains a small preponderance of oily matter, as the principal part of the milder toilet soaps now do, it mechanically softens the skin and promotes its smoothness. Almond, Naples, and Castile soaps are esteemed for these properties, and milk of roses, cold cream, and almond powder, (paste,) are used for a similar purpose. To produce an opposite effect, and to harden the cuticle, spirits, astringents, acids, and astringent salts are commonly employed. The frequent use of hard water has a similar effect. The application of these articles is generally for the purpose of strengthening or preserving any given part against the action of cold, moisture, &c.; as the lips, or mammæ, from chapping, or the hands from contracting chilblains; but in this respect, oils, pommades, and other oleaginous bodies, are preferable.

Another class of cutaneous cosmetics are employed to remove freckles and eruptions. Among the most innocent and valuable of these, is Gowland's lotion, which has long been a popular article, and deservedly so, for it not only tends to impart a delightful softness to the skin, but is a most valuable remedy for many obstinate eruptive diseases, which frequently resist the usual methods of treatment. Bitter almonds have been recommended to remove freckles, (Celsus,) but moistening them with a lotion made by mixing 1 oz. of rectified spirit of wine, and a teaspoonful of muriatic acid, with 7 or 8 oz. of water, is said to do this more effectually. A safe and excellent cosmetic is, an infusion of horseradish in cold milk. (Withering.)

Skin paints and stains are employed to give an artificial bloom, or delicacy to the skin. Rouge and carmine are the articles most generally used to communicate a red color. The former is the only cosmetic that can be employed, without jury, to brighten a lady's complexion. The la though possessing unrivalled beauty, is apt to part a *sallowness* to the skin by frequent Starch powder is employed to impart a white and is perfectly harmless. The American la who are very fond of painting their necks wi use finely-powdered magnesia, which is also very innocent substance. Several metallic c pounds, as trisnitrate, subchloride, and oxide bismuth, (pearl white, Fard's white, &c.,) ca nate of lead, (flake white,) white precipitate, are frequently used to revive faded complexi but they are not only injurious to the skin, but as poisons, if taken up by the absorbents. T nitrate of bismuth, (pearl white,) probably least injurious of these articles, has caused s modic tremblings of the muscles of the face, e ing in paralysis. (Vogt. Pharm.) The employm of liquid preparations, containing sugar of le which are commonly sold under the name of m of roses, cream of roses, &c., is equally injuri Another disadvantage of these white meta preparations is, that they readily turn black, w exposed to the action of sulphureted hydro gas, or the vapors of sulphur, which freque escape into the apartment from coal fires. Th are many instances recorded, of a whole comp being suddenly alarmed, by the pearly comple of one of its belles being suddenly transform into a sickly gray or black. A friend of the w ter's was once startled at a Christmas party observing the one side of a lady's face and ne which was exposed to the fire, become discol in this way, and was so amused on learning cause, that he has since played two or three jo of the kind on some petulant old ladies, rema able for the great attention they pay to their t let. In conclusion it may be remarked, that best *purifiers of the skin* are soap and wa followed by the use of a *coarse* cloth, in opp tion to the *costly* and *soft diapers* that are c monly employed; and the best *beautifiers*, HEALTH, EXERCISE, and GOOD TEMPER.

COSMETIC, SIMPLE. *Prep.* Soft soa lb.; melt over a slow fire with a gill of sweet add half a teacupful of fine sand, and stir mixture together until cold. The shelly sea-s sifted from the shells, has been found better that which has no shells.

Remarks. This simple cosmetic has, for so years past, been used by many ladies who a markable for the delicate softness and wh of their hands, which they, in a great m attribute to the use of it. Its cheapness is a recommendation.

COUGH. The sudden and violent exp of air from the lungs. It is generally sy matic of other affections, but is sometimes i thic. Many cases of cough depend upon th tension of catarrh to the trachea and bro which thus become loaded with mucus or ph which they endeavor to throw off by the co sive effort called coughing. In some case caused by a vitiation and inspissation of the s tions, arising from the imperfect action of th sorbents; this is the common cause of th cough of old people. Idiopathic cough is not sidered dangerous in itself, or while runni

regular course, but it is often productive of most serious consequences, by superinducing the inflammation of some organ, or laying the foundation of phthisis.

Cough is sometimes attended by copious expectoration, and at other times exists without any; it has hence been distinguished into *moist* or *mucous* cough, and *dry* cough.

Treat. The treatment of common catarrhal cough consists in allaying the irritation as much as possible, by demulcents and expectorants, as mucilaginous drinks and lozenges, which act upon the glottis, and sympathetically upon the trachea and bronchiæ. Among the first may be mentioned, almond milk, barley water, refined Spanish juice, gum arabic, and a mixture of the last two made into lozenges; among the second, the most innocent and convenient is ipecacuanha, in the shape of lozenges, 2 or 3 of which may be sucked whenever the cough is troublesome. A light diet should be adopted, the bowels kept *slightly* relaxed by mild aperients, and a mild and equable temperature sought as much as possible. When this plan does not succeed, recourse may be had to an emetic, followed by small doses of Dover's powders, and extract or tincture of henbane, or squill pill. When a cough is troublesome at night, and unattended with fever, a small dose of laudanum, or tincture of henbane, taken on going to rest, will generally procure sleep. In the treatment of dry cough the more stimulating expectorants are useful, as garlic, ammoniacum, styrac, and benzoin, combined with narcotics and sedatives, as henbane, hemlock, and opium. A diaphoretic opiate is also very useful, especially in the cough of old people.

COUGH, POPULAR REMEDIES FOR. I. (*Draughts.*) *a.* Sirup of poppies 1 dessert-spoonful; antimonial wine 20 drops; mix for a dose, to be taken in a little warm tea on going to bed. *b.* Laudanum 30 drops; vinegar and honey, of each, a dessert-spoonful; ipecacuanha wine 25 drops; mix for one dose, as last.

II. (*Emulsion.*) Milk of almonds 4 oz.; sirup of squills and tolu, of each, 1 oz.; mix. *Dose.* A tablespoonful every 2 hours.

III. (*Mixtures.*) *a.* Tincture of tolu ½ oz.; paregoric elixir and tincture of squills, of each, ½ oz.; sirup of white poppies 1 oz.; mix. *Dose.* 1 teaspoonful in barley water, whenever the cough is troublesome. *b.* Milk of ammoniacum 4 oz.; sirup of squills 2 oz.; mix. A tablespoonful 3 or 4 times daily, for the cough of old persons. *c.* (*Dr. Munro's.*) Paregoric ½ oz.; sulphuric ether and tincture of tolu, of each, ¼ oz.; mix. *Dose.* A teaspoonful night and morning, or when the cough is troublesome, in a little warm water. *d.* (*Dr. Radcliff's.*) Sirup of poppies, sirup of squills, and paregoric, of each, ½ oz.; mix. *Dose.* As last.

COUMARINE. The fragrant volatile principle of the tonka bean, the diptera odorata of Wildenow. It is dissolved out by ether, and purified by alcohol. It crystalizes in small prisms.

COWHAGE. *Syn.* COWITCH. DOLICHIS PUBES. The down which grows upon the pods of the mucuna pruriens. (Dolichos pruriens.) It occasions violent itching, when it comes in contact with the skin, which can only be allayed by a solution of given vitriol or oil. It is frequently administered as a vermifuge, made into a confection, by scraping the hair off a pod into treacle, sirup, or honey, for a morning dose, which is repeated for 3 or 4 successive days, followed by a brisk purge.

COWS, MILCH, (CHOICE OF.) As to a choice of breeds for a private family, none in England, (says Mr. Lawrence,) probably combine so many advantages as the Suffolk dun-cows. They excel both in quantity and quality of milk; they feed well after they become barren; they are small-sized, and polled or hornless; the last a great convenience. The horns of cows which butt and gore others, should be immediately broad tipped. There is a breed of polled Yorkshire, or Holderness cows, some of them of middling size, great milkers, and well adapted to the use of families, where a great quantity of milk is required, and where price is no object, and food in plenty. If richer milk and a comparison of the two famous breeds be desired, one of each may be selected, namely, the last mentioned, and the other of the midland county, or long-horned species. Color is so far no object, that neither a good cow nor a good horse can be of a bad color; nevertheless, in an ornamental view, the sheeted and pied stock of the Yorkshire shorthorns make a picturesque figure in the grounds.

The Alderney cows yield rich milk upon less food than larger stock, but are seldom large milkers, and are particularly scanty of produce in the winter season. They are, besides, worth little or nothing as barreners, not only on account of their small size, but their inaptitude to take on fat, and the ordinary quality of their beef.

Feeding. There is nothing equal to rich pasturage for milch cows, but at such seasons, and during such weather that this cannot be procured, good hay, with turnips, carrots, potatoes, or mangel-wurzel, must be given instead, along with a sufficient quantity of clean water. The principal cowkeepers of the metropolis have dairy-farms in the suburbs, where the animals are turned out a portion of every day in the year, except during heavy rains, or when the ground is covered with snow. They are also well supplied with brewers' grains, tares, beet-root, &c., and great care is taken that they get fresh air, and exercise sufficient for their health. Such cows yield a large quantity of wholesome milk, very different to much that is sold in London, obtained from cows kept in stables, cellars, and other confined situations, and which are seldom supplied with green food. It has lately been shown by Boussingault, that mangel-wurzel, so commonly used for feeding cattle, is insufficient as an article of food. He found that a cow fed on this substance ceases to give her usual quantity of milk, and that even when other food was given along with it, the animal yielded less than her ordinary quantity. Before giving turnips to cows, the rotten or bad ones should be picked out, as it is said that even the presence of a single damaged one will flavor the milk, and perhaps spoil a whole dairy of cheese or butter.

Economy of a cow. The annual consumption of food per cow, if turned to grass, is from an acre to an acre and a half in the summer, and from a ton to a ton and a half of hay in the winter. A cow may be allowed 2 pecks of carrots

perceive any good effects to result from its administration.

COPAIBIC ACID. *Syn.* CAPIVIC ACID. The yellow brittle resin of balsam of copaiba. It is prepared by digesting the resin (left after distilling the oil from the balsam) in alcohol, which dissolves the acid resin, but leaves the viscid one. It may be purified by re-solution in alcohol. It forms about 50% of the balsam.

Prop. An amber-colored, brittle, semi-crystalline, resinous substance, soluble in alcohol, ether, and oils, reddens litmus paper, and forms salts with the bases, called copaivates. These may generally be made by dropping into a solution of the acid in alcohol, an alcoholic solution of a soluble salt of the base. The copaivates of potash, soda, and ammonia are easily prepared, by adding to an alcoholic solution of the acid another of the pure alkali, until it be neutralized, when the salts may be obtained by careful evaporation. Copaivate of silver is formed by neutralizing the acid with nitrate of silver, both being dissolved in alcohol, and then adding a little liquor of ammonia, when a white crystalline precipitate will subside. The copaivates of lead, lime, and iron, as well as several others, may be made in a similar manner.

Copaivate of magnesia may be made by adding copaivate of potassa to a solution of epsom salts. All these salts are easily decomposed by acids.

COPAL. *Syn.* GUM COPAL. A resinous substance, which exudes spontaneously from the Rhus copallinum, and the Elæocarpus copalifer. When of good quality, it is too hard to be scratched by the nail, and has a conchoidal fracture. It dissolves with difficulty, and this, combined with its extreme hardness, renders it very valuable for making varnishes.

SOLVENTS. I. *Caoutchoucine;* sparingly. II. Equal parts of *caoutchoucine* and *alcohol*, of ·825; freely soluble in the cold. III. *Absolute alcohol*, added gradually to the copal, previously rendered gelatinous by water of ammonia, assisting the union with heat. IV. *Alcohol* added to the copal, previously softened with ether. V. *Absolute alcohol* 1½ parts, digested on copal 1 part for 24 hours. (Unverdorben.) VI. *Alcohol*, to which a little camphor has been added. VII. *Ether;* and this solution may be diluted with alcohol. VIII. *Oils of rosemary* and *lavender*, (spike;) too expensive for general use. IX. *Copal*, heated until it fuses, acquires the property of dissolving in turpentine and alcohol. X. *Copal*, reduced to powder and exposed for some time to the air, also becomes soluble in alcohol and turpentine. XI. *Drying linseed oil*, at nearly the boiling point, dissolves copal, and will bear dilution with spirits of turpentine as soon as it has cooled sufficiently. This is the common way of making copal varnish. XII. *Ammonia* enables oil of turpentine to dissolve copal; but it requires such nice management of the fire, that it seldom succeeds completely. (Lewis.) XIII. *Powdered copal*, triturated with a little camphor, softens and becomes a coherent mass; and camphor, added either to alcohol or oil of turpentine, renders it a solvent of copal. ½ oz. of camphor is sufficient for 1 quart of oil of turpentine, which should be of the best quality; and the copal, about the size of a large walnut, should be broken into very small pieces, but not reduced to a fine powder. The mixture should be set on a fire so brisk as to make it boil almost immediately. The vessel should be of tin or other metal, strong, shaped like a wine-bottle with a long neck, and capable of holding 2 quarts. The mouth should be stopped with a cork, in which a notch is cut to prevent the vessel from bursting. (Sheldrake.) XIV. A good varnish may be made by pouring upon the purest lumps of copal, reduced to a fine mass in a mortar, colorless spirits of turpentine, to about one third higher than the copal, and triturating the mixture occasionally in the course of the day. Next morning it may be poured off into a bottle for use. Successive portions of oil of turpentine may thus be worked with the same copal mass. (Varley, Tilloch's Mag. 51.)

⁂ In all the above cases the copal should be reduced to a *coarse* powder. A *fine* powder is apt to stick together and form hard lumps. The solution of copal, even in its most ready solvents, is attended with some difficulty, and frequently miscarries in the hands of the inexperienced. A mixture of caoutchoucine and alcohol (as in No. II.) is an exception.

COPAL, MELTED. Obtained by holding the gum before a good fire, so that as soon as the copal melts, it may drop into a pan of water: a kind of oil separates from it, and the copal becomes soluble in spirits of wine, and still more so if the melting is repeated.

COPAL, POWDERED. Copal reduced to powder and exposed to the air in a thin stratum, on sieves covered with paper, for 3 or 4 months. Soluble in alcohol.

COPPER. (From *cuprum*, a corruption of *κύπρος*, from the island of Cyprus, whence it was formerly brought.) A red-colored metal, too well known to require description.

Hist. Copper and its alloys appear to have been known to the most remote ages of antiquity. Brass, an alloy of copper, is mentioned by Moses (Job, xxviii.) upwards of 1600 years before the birth of Christ. (Hales.) This metal is found in the metallic state, and in combination with oxygen, sulphur, acids, and other minerals, and in the organic kingdom, in the ashes of plants, and in the blood of animals. (Sarzeau.) The copper of commerce is principally prepared from copper pyrites, a mixed sulphuret of iron and copper, found in Cornwall, and other parts of the world.

Prep. Copper is only prepared from its ores on the large scale. The copper pyrites is first roasted, and then smelted, by which process "*coarse metal*" is produced; this is again submitted to calcination and smelting, when "*fine metal*" is obtained. It afterwards undergoes the process of refining and toughening.

Prop. This metal is malleable and ductile. It has a specific gravity of 8·8 to 8·9, fuses at about 2000° Fahr., and volatilizes at higher temperatures. It forms numerous compounds, all of which are more or less poisonous.

Char. and Tests. The solutions of copper possess a blue or green color, and yield a blue precipitate with soda or potassa. Ammonia produces a bluish-white precipitate, soluble in an excess of the precipitant, forming a deep blue solution. Prussiate of potash gives a reddish-brown precipitate, sulphureted hydrogen and hydrosulphurets, a black

me. A polished iron plate, immersed in an acidulous solution of copper, becomes coated with that metal.

Estim. The quantity of copper present in any compound, may be estimated by throwing it down from its solution by pure potassa, after which it must be carefully collected, washed, dried, ignited, and weighed. This will give the quantity of the oxide from which its equivalent of metallic copper may be calculated; every 5 parts of the former being (as near as possible) equal to 4 of the latter. Copper may also be precipitated at once in the metallic state, by immersing a piece of polished steel into the solution, but this method will not give very accurate results. Copper may be separated from lead by adding sulphuric acid to the nitric solution, and evaporating to dryness, when water digested on the residuum will dissolve out the sulphate of copper, but leave the sulphate of lead behind. From this solution the oxide of copper may be thrown down as before. Copper may be separated from zinc by sulphureted hydrogen, which will throw down a sulphuret of copper, which may be dissolved in nitric acid, and treated as above.

Uses. The applications of copper in the arts are too well known to require notice. In medicine, 3 or 4 grains of the filings were formerly given in rheumatism, and to prevent hydrophobia.

Ant. Copper in the metallic state appears to be inert, but most of its compounds are poisonous. The antidotes are, the white of egg, milk, or flour mixed with water. Iron filings (Payen, Chevallier, Dumas) and the prussiate of potash have also been recommended. A drachm or more of the latter may be taken dissolved in water, and ½ oz. or more of the former, ad libitum. Sugar has also been proposed as an antidote. (Duval, Postel.)

COPPER, ALLOYS OF. With *zinc* copper forms *brass*; with *tin*, *bronze*, *bell*, and *cannon metal*. An alloy made with 100 parts of copper and 50 of tin, forms *speculum metal*. *White copper* is formed by the addition of metallic arsenic, and *German silver* is a mixture of nickel, zinc, and copper. See these articles in their alphabetical places.

COPPER, ACETATES OF. I. (*Neutral Acetate. Syn. Distilled Verdigris. Binacetate of Copper. Crystallized Verdigris.*) *Prep.* Dissolve verdigris in vinegar, with the aid of heat, and crystallize. It forms dark green or blue crystals.

II. (*Diacetate. Syn. Verdigris. Ærugo.*) Formed by exposing sheets of copper to the vapor of acetic acid, in a warm situation. (See VERDIGRIS.) It forms a green or bluish-green powder.

III. (*Sesquibasic Acetate.*) The blue portion of verdigris, soluble in water.

IV. (*Trisacetate.*) The green insoluble portion of verdigris.

COPPER, ARSENITE OF. *Syn.* SCHEELE'S GREEN. *Prep.* Mix a solution of 2 parts of sulphate of copper in 44 of water, with a solution of 2 parts of potash of commerce, and 1 of pulverized arsenious acid, also in 44 of water. Both solutions being warm, the first is to be gradually poured into the second. The grass-green insoluble precipitate is to be washed with water.

COPPER, AMMONIURETED. *Syn.* CUPRO-SULPHATE OF AMMONIA. AMMONIATED COPPER, (P. E.) *Prep.* (*Ammonio-sulphate of Copper*, P. L.) Sulphate of copper ℥j; sesquicarbonate of ammonia ℥iss. Rub them together until carbonic acid ceases to evolve, then wrap it up in bibulous paper and dry it in the air.

Prop. By heat ammonia is evolved, and oxide of copper remains. Its aqueous solution changes the color of turmeric, and a solution of arsenious acid renders it green. (P. L.)

Uses. Employed in pyrotechny. It has been given in doses of ½ to 5 grs. in chorea, epilepsy, hysteria, &c., but it is principally employed as an injection and as a collyrium, in opacity of the cornea.

Remarks. Great care must be taken in drying this article, as it is apt not only to lose a large portion of its weight, but become of an inferior color. Both the ingredients should be separately reduced to powder before mixing.

COPPER, BEAN-SHOT. *Prep.* Melt copper, and pour it in a small stream into boiling water. It is in small lumps like peas or beans, hence its name.

COPPER, BLANCHED. *Prep.* Fuse copper with $\frac{1}{16}$ of its weight of neutral arsenical salt, under a flux of calcined borax, charcoal, and powdered glass.

COPPER, CARBONATE OF. *Syn.* DICARBONATE OF COPPER. MINERAL GREEN. *Prep.* Add a solution of carbonate of soda or potassa to a hot solution of protosulphate of copper.

Remarks. The beautiful green mineral called *malachite*, is a hydrated dicarbonate of copper. If the solution of copper in the above formula be employed cold, the precipitate has a bluish-green color. (See VERDITER.)

COPPER, CHLORIDES OF. *Prep.* I. (*Subchloride. Syn. Dichloride of Copper. Resin of ditto. White muriate of ditto.*) Distil a mixture of 1 part of copper filings, with two parts of corrosive sublimate.

II. (*Chloride. Syn. Muriate of Copper. Hydrochlorate of ditto. Protochloride of ditto.*) Dissolve protoxide of copper in muriatic acid, evaporate and crystallize.

Remarks. This salt forms green needles, is deliquescent, soluble in alcohol, and when heated, (under 400°,) loses its water, and becomes anhydrous chloride of copper, and assumes the form of a yellow powder. The first of these preparations is sometimes called the protochloride or muriate; the second the deutochloride.

COPPER, CHROMATE OF. *Prep.* Precipitate a salt of copper, with neutral chromate of potash; or dissolve hydrated peroxide or carbonate of copper in chromic acid. Caustic ammonia dissolves this salt, forming a magnificent dark-green liquid, from which, by the admixture of spirit of wine, ammonio-chromate of copper, or cupro-chromate of ammonia, is disengaged in the form of a powder of a splendid, rather dark-green appearance. The readiest way of preparing this permanent and beautiful color, is to add solution of chromate of potash to ammoniacal sulphate of copper.

COPPER, FEATHER-SHOT. *Prep.* Melted copper, poured in a small stream into cold water. It forms small pieces, with a feathered edge, hence the name. It is used to make solution of copper.

sale druggist in the city, produces an excellent article.

II. Hay saffron, cassia, and turmeric, of each 4 oz.; cardamoms 1 oz.; starch 8 oz.; precipitated chalk 2 lbs.; white sugar 4 lbs.; oil of nutmegs 2 drachms; oil of cloves 3 drachms. Reduce the dry ingredients to fine powder, and pass it through an 80 hole sieve, then add the oils, and after well mixing, pass it through a coarse sieve, (about 40 holes to the inch,) to ensure the whole being perfectly mixed.

The following form produces a powder possessing great depth and brilliancy of color.

III. Hay saffron 4 oz.; turmeric 3 oz.; powdered starch 8 oz.; precipitated chalk 2 lbs.; white sugar 4 lbs.; oils of cloves and cassia, of each 3 drachms; oil of nutmegs 2 drachms; essence of cardamoms 1 oz. *Proc.* Boil the saffron and turmeric in 1 gallon of water, placed in a bright copper pan, for 10 minutes, then, without straining, add the chalk, starch, and sugar; mix well, and continue stirring until the mixture becomes quite stiff, then break it up and dry it until fit for powdering. This must be performed in a water or steam bath. To the powder, passed through a fine sieve, as before, the oils and tincture must be added, and after being well mixed, and passed through a coarse sieve, it should be placed in a jar or bottle, and bunged up close.

Remarks. In the wholesale trade this article is kept under two forms: one in powder, as ordered by the College, and commonly called, for distinction sake, "*pulvis confectionis aromaticæ;*" the other mixed up ready for use. In preparing the latter, it is a common plan to make a strong infusion or decoction of the saffron, and to use it to mix up the other ingredients. Some persons follow the method described in the last formula, mixing up the powder to a proper consistence with water before adding the aromatics. When the price of *precipitated* chalk is an objection to its use, *prepared* chalk may be used instead. This confection is cordial, stimulant, and antacid. *Dose.* 10 to 60 grs.

CONFECTION OF BLACK PEPPER. *Syn.* WARD'S PASTE. *Prep.* (*Confectio Piperis Nigri,* P. L.) Black pepper and elecampane root, of each lb. j; fennel seed lb. iij; honey and white sugar, of each lb. ij; mix.

Remarks. The common practice is to keep the dry ingredients ready mixed in a bottle, and only to add the honey as wanted. The proportions are 2 parts of the latter to 7 of the mixture. The *dose* is 1 to 2 drachms 2 or 3 times a-day, in piles, fistula, &c. It should be persevered in for 2, 3, or 4 months, (Sir B. Brodie;) and as it is apt to accumulate in the bowels, its use should be accompanied by mild aperients. (Pereira.)

CONFECTIONS OF CASSIA. *Syn.* ELECTUARIUM CASSIÆ, (P. L. 1788.) *Prep.* (*Confectio Cassiæ,* P. L.) Fresh cassia pulp lb. ss.; manna ℥ij; tamarind pulp ℥j; sirup of roses f℥viij. Bruise the manna and dissolve it in the sirup, then add the pulps and evaporate to a proper consistence.

CONFECTION OF HEMLOCK. (Dr. Osborne.) *Prep.* Fresh leaves of hemlock and moist sugar equal parts; beat them to a confection in a mortar.

CONFECTION OF OPIUM. *Syn.* PHILONIUM ROMANUM, (P. L. 1720.) DITTO LONDINENSE, (P. L. 1745.) CONFECTIO OPIATA, (P. L. 1788.) DITTO OPII, (P. L. 1809, and since.) *Prep.* (P. L.) Powdered opium ʒvj; long pepper ℥j; ginger ℥ij; caraways ℥iij; tragacanth ʒij; all in fine powder; sirup f℥xvj. Mix.

Use and Dose. This confection is intended as a substitute for the *mithridate* and *theriaca* of the old Pharmacopœia. It is stimulant and narcotic, and is given in flatulent colic and diarrhœa unaccompanied by fever. The dose is from 15 to 50 grs.

CONFECTION OF ORANGE PEEL. *Syn.* CONSERVA FLAVEDINIS CORTICUM AURANTIORUM, (P. L. 1720 and 1745.) DITTO CORTICIS EXTERIORIS AURANTII HISPALENSIS, (P. L. 1788.) DITTO AURANTIORUM, (P. L. 1824.) DITTO AURANTII, (P. L. 1809 and 1836.) *Prep.* (P. L.) The external rind of the fresh orange, separated by rasping, lb. j; white sugar lb. iij. Beat the rind in a stone mortar with a wooden pestle, then add the powdered sugar, and beat the mixture until the two are perfectly incorporated.

Remarks. This confection is tonic and stomachic, and is principally used as a vehicle for the exhibition of tonic powders.

CONFECTION OF PEPPERMINT. *Prep.* Green peppermint 4 oz.; powdered white sugar 12 oz.; beat them together as last.

Use. Anti-emetic and flatulent. Given in colic, &c., in the form of a bolus, or made into a mixture.

CONFECTION OF THE DOG ROSE. *Syn.* CONFECTION OF HIPS. CONSERVA FRUCTUS CYNOSBATI, (P. L. 1720 and 1745.) DITTO CYNOSBATI, (P. L. 1788.) DITTO ROSÆ CANINÆ, (P. L. 1809, and since.) *Prep.* (P. L.) Pulp of the dog rose lb. j; powdered refined sugar ℥xx; mix by a gentle heat in an earthen vessel.

II. Pulped hips 2 cwt.; fine white sugar 2½ cwt.; incorporate them without applying heat.

Remarks. Both this and the following confection has a brighter color, if made without heat, or touching metallic vessels. On the small scale it is made by beating the ingredients together in a marble mortar, but in large quantities by grinding in a mill. It is slightly laxative, and is principally used for forming pills. It candies by keeping.

CONFECTION OF THE RED ROSE. *Syn.* CONSERVA ROSARUM RUBRARUM, (P. L. 1745.) DITTO ROSÆ, (P. L. 1788.) DITTO ROSÆ GALLICÆ, (P. L. 1809 and 1824.) CONFECTIO ROSÆ GALLICÆ, (P. L. 1836.) *Prep.* (P. L.) Petals of the red rose lb. j; refined sugar lb. iij; beat the petals in a stone mortar, then add the sugar, and again beat until thoroughly incorporated.

Remarks. On the large scale this is prepared like the confection of hips. It is astringent and tonic, and principally used for forming pills. If taken alone, the dose is 1 to 2 drachms.

CONFECTION OF RUE. *Syn.* ELECTUARIUM E BOCCIS LAURI, (P. L. 1720, 1745.) CONFECTIO RUTÆ, (P. L. 1809, and since.) *Prep.* (P. L.) Dried rue, caraway, and laurel berries, of each ℥iss; sagapenum (true) ℥ss; black pepper ʒij; honey ℥xvj. Reduce the dry ingredients to very fine powder, and when wanted for use, make them into a confection with the honey.

Use, &c. It is antispasmodic; in enemas 30 to

60 grs., with half a pint of gruel, for flatulent colic, &c.

CONFECTION OF SCAMMONY. *Syn.* ELECTUARIUM CARYOCOSTINUM, (P. L. 1720.) DITTO E SCAMMONIO, (P L. 1745.) DITTO SCAMMONII, (P. L. 1809 and 1788.) CONFECTIO SCAMMONEÆ, (P. L. 1809 and 1824.) *Prep.* (*Confectio Scammonii* P. L.) Scammony ℥iss; cloves and ginger, of each, ʒvj; oil of caraway fʒss. Reduce the ingredients to a very fine powder, and when wanted for use, make them into a confection with sirup of roses, and lastly add the oil.

Use, &c. Cathartic in doses of 10 to 30 grs.

CONFECTION OF SENNA. *Syn.* LENITIVE ELECTUARY. ELECTUARIUM SENNÆ, (P. L. 1788.) CONFECTIO SENNA, (P. L. 1809, and since.) *Prep.* (P. L.) Senna ℥viij; figs lb. j; pulp of tamarinds, prunes, and cassia, of each, lb. ss.; coriander seeds ℥iv; liquorice ℥iij; sugar lb. iiss; water 3 pints. *Proc.* Rub the senna and corianders in a mortar, and separate by sifting ℥x of the mixed powders. Boil the figs and liquorice in the water, until reduced to one half; then press and strain the liquor. Evaporate the strained liquor until only 24 fluid ounces remain, then add the sugar, and when dissolved, mix in the pulps, and lastly the powder.

Use, Dose, &c. Confection of senna is a gentle and pleasant purgative, and well adapted for persons suffering from piles, and as a laxative during pregnancy. The dose is ¼ to ½ oz. taken at bedtime or early in the morning.

Remarks. Perhaps there is no one pharmacopœial preparation which it is more difficult to obtain of good quality than the above. The absolute cost of an article prepared according to the directions of the College, will be somewhere about 1s. 9*d.* per lb.; but there are many wholesale drug houses vending confection of senna, which they warrant as genuine, at from 9*d.* to 1*s.* a pound. Dr. Paris (in his Pharmacologia) very truly remarks, that "the directions of the Pharmacopœia are very rarely followed." I understand that considerable quantities are manufactured, into which unsound and spoiled apples enter as a principal ingredient. The following forms are, to my knowledge, employed by some members of the trade.

II. Powdered senna, pulp of tamarinds, cassia, and prunes, of each, 1½ lb.; powdered corianders ¾ lb.; Spanish juice ½ lb.; simple sirup 12 lbs.

III. As the above, omitting the cassia pulp, and adding 2 lbs. more tamarind pulp.

Both these articles are labelled P. L., and sent out as genuine, and that when no competition as to price exists. The cheaper article is made as follows:

IV. Common prunes and tamarinds, of each, 16 lbs.; treacle ¾ cwt.; species (a compound of senna dust and small senna, mixed with 3 lbs. of coriander seeds, and strengthened with jalap, all ground to a fine powder) 18¾ lbs. To this is frequently added ¼ cwt. of rotten or inferior apples, which are pulped with the prunes and tamarinds. This article is not unfrequently labelled "CONF. SENNÆ VER." by the conscientious tradesman.

CONFECTION OF SULPHUR, (COMPOUND.) *Prep.* (St. B. H.) Precipitated sulphur ℥ss; cream of tartar ʒj; honey ℥j; mix As a laxative in piles, &c. *Dose.* ℥ss.

CONFECTION OF STEEL. *Syn.* CONFECTION OF CARBONATE OF IRON. *Prep.* Confection of orange-peel and sesquioxide of iron, (P. L.,) of each, 4 oz.; powdered white sugar 6 oz.; simple sirup 2 oz.; mix. Aromatic and tonic. *Dose.* A teaspoonful to ½ oz. twice or thrice daily.

CONGELATION, (from *congelo*, to freeze.) IN CHEMISTRY. The conversion of a liquid into a solid state, by the action of cold.

The production of an extreme degree of cold is often of the utmost importance in chemical operations, and an easy method of doing so is consequently a desideratum. The means hitherto adopted for this purpose have either depended upon the sudden liquefaction of solids, or the abstraction of heat by rapid evaporation. The loss of sensible heat, by the first method, is the basis of the various processes of producing cold by what are commonly called freezing mixtures, all of which act upon the principle of liquefying solid substances without supplying heat. The caloric of liquidity being in these cases derived from that previously existing in the solid itself in a sensible state, the temperature must necessarily fall. The degree of cold produced, depends upon the quantity of heat which is thus diffused through a larger mass, or which, as it were, disappears, and this is dependent on the quantity of solid matter liquefied, and the rapidity of the liquefaction. Saline compounds are the substances most frequently employed, and those which have the greatest affinity for water, and thus liquefy the most rapidly, produce the greatest degree of cold. Thus it is, that chloride of calcium and nitrate of ammonia, when dry and in fine powder, if suddenly mixed with water, produce extreme cold. The latter, suddenly mixed with an equal weight of water at 50°, will sink the thermometer to +4°, or 28° below the freezing point. The most common and convenient freezing mixture, when snow can be procured, is formed by mixing 2 parts of that substance with 1 part of sea-salt. This will sink the thermometer to —5°, or 37° below the freezing point of water. Equal parts of these substances produce a degree of cold marked by the zero of Fahrenheit's thermometer, and is the standard taken for graduating that instrument. Mr. Walker, a gentleman who fully investigated this subject, recommends the following proportions for the production of extreme cold.

PEAU. BEZETTA CŒRULEA. *Prep.* I. Color pieces of clean linen with auvergne or ground archel, (lichen parellus.)

II. Dip pieces of clean linen into the juice of mulberries, blood-red grapes, lees of red wine, &c.

Use. To color jellies and confectionary, and the rind of cheeses.

CLARIFICATION. This word (from *clarus*, clear, and *facio*, I make) means, properly, any process of freeing a fluid from heterogeneous matter, and thus includes filtration. In its commoner sense, however, it is applied to the process of clearing liquids by the addition of some substance that either inviscates the feculous matter, and subsides with it to the bottom, or, that induces such a change in its nature or bulk, that it subsides by its own density, in each case leaving the liquor transparent. Albanum, gelatin, acids, certain salts, blood, lime, plaster of Paris, alum, heat, alcohol, &c., serve in many cases for this purpose. The first is used under the form of white of egg, for the clarification of sirups, as it combines with the liquid when cold, but on the application of heat, rapidly coagulates and rises to the surface, carrying the impurities with it, forming a scum which is easily removed with a skimmer. It is also much used for fining wines and liqueurs, particularly the red wines and more limpid cordials. Gelatin, under the form of isinglass, dissolved in water, or weak vinegar, is used to fine white wines, beer, cider, and similar liquors, that contain a sufficient quantity of either spirit or astringency (tannin) to induce its precipitation. Sulphuric acid is frequently added to weak liquors for a similar purpose, either alone, or after the addition of white of egg, or gelatin, both of which it rapidly throws down in an insoluble form. A pernicious practice exists among some unprincipled parties, of using certain salts of lead and potash to clear their liquors, especially those that are expected to sparkle in the glass, as cordial, gin, &c. For this purpose, a little sugar of lead, dissolved in water, is first mixed up with the fluid, and afterwards about half its weight of sulphate of potash, also dissolved in water, is added, and the liquor is again roused up. By standing, the sulphate of lead, formed by this mixture, subsides, and leaves the liquor clear. Blood is used in the same way as isinglass or white of eggs, for fining red wines, beer, and porter. Lime, alum, alcohol, and heat, act by curdling or coagulating the feculencies, and thus, by increasing their density, induce their subsidence. Plaster of Paris acts partly like the above, and partly like albumine, or gelatin, by enveloping and forcing down the suspended matter. Sand is often sifted over liquors for the simple purpose of acting by its gravity, but appears to be quite useless. The juices of plants are clarified by heat, which coagulates the albumine they contain. Marl, or clay, is frequently used to clear cider and perry. A strip of isinglass is generally employed to clarify coffee. (See WINES, BREWING, CORDIAL, COFFEE, INFUSION.)

CLEANING. The best way to clean a house is to *keep it clean* by a daily attention to small things, and not allow it to get into such a state of dirtiness and disorder as to require great and periodical cleanings. Some mistresses, and also some servants, seem to have an idea that a house should undergo "regular cleanings," or great washing and scrubbing matches once every three or six months, on which occasions the house is turned almost inside out, and made most uncomfortable. All this is bad economy, and indicates general slovenliness of habits. (Chambers.)

CLEAR-STARCHING. This is practised as follows: "Rinse the articles in three waters, dry them, and dip them in a thick starch, previously strained through muslin; squeeze them, shake them gently, and again hang them up to dry; and when dry, dip them twice or thrice in clear water, squeeze them, spread them on a linen cloth, roll them up in it, and let them lie an hour before ironing them. Some persons put sugar into the starch to prevent it sticking while ironing, and others stir the starch with a candle to effect the same end; we object to these practices as injurious to the article starched, or as very nauseous. The best plan to prevent sticking is to make the starch well, and to have the irons quite clean and highly polished."

CLOTH, CLEANING AND SCOURING OF. The common method of cleaning cloth is by beating and brushing, unless when very dirty, when it undergoes the operation of scouring. This is best done on the small scale, as for articles of wearing apparel, &c., by dissolving a little curd soap in water, and, after mixing it with a little ox-gall, to touch over all the spots of grease, dirt, &c., with it, and to rub them well with a stiff brush until they are removed, after which the article may be well rubbed all over with a brush or sponge dipped into some warm water, to which the previous mixture and a little more ox-gall has been added. When this has been properly done, it only remains to thoroughly rinse the article in clean water until the latter passes off uncolored, when it must be hung up to dry. For dark-colored cloths the common practice is to add some fuller's earth to the mixture of soap and gall. When *nearly* dry, the nap should be laid right, and the article carefully pressed, after which a brush, moistened with a drop or two of olive oil, should be several times passed over it, which will give it a superior finish. Cloth may also be cleaned in the dry way as follows:—First, remove the spots as above, and, when the parts have dried, strew clean damp sand over it, and beat it in with a brush, after which brush the article with a hard brush, when the sand will readily come out, and bring the dirt with it. *Black cloth* which is very rusty, should receive a coat of reviver after drying, and be hung up until the next day, when it may be pressed and finished off as before. *Scarlet cloth* requires considerable caution. After being thoroughly rinsed, it should be repeatedly passed through cold spring water, to which a tablespoonful or two of solution of tin has been added. If much faded, it should be dipped in a scarlet dye-bath. *Buff cloth* is generally cleaned by covering it with a paste made with pipe-clay and water, which, when dry, is rubbed and brushed off.

Fruit spots and similar stains may frequently be removed by holding the part over a common brimstone match, lighted, or by water acidulated with a little salt of lemons, oxalic or muriatic acid; but care must be taken not to apply this liquid to colors that it will injure.

The stains of acids may be removed by washing the part with a little spirits of hartshorn or

liquid ammonia; *those of alkalis*, by water acidulated with lemon juice or tartaric acid.

Grease spots may generally be taken out by means of a little soft soap; or, if the color be delicate, or a false dye, a little ox-gall or curd soap will be better. These must be used as above described. *Stains of painters' oils, wax, paints, or varnishes*, will not usually yield to the above plan; in these cases, a simple way is to soak the part in spirits of turpentine, and, when softened, to wash it off with the same fluid. Ether or essential oil of lemons will also quickly remove these spots, but is too expensive for general use.

CLOTH, INCOMBUSTIBLE. This is made of fibres of asbestos by weaving. It will bear a considerable heat without injury. Cotton and linen fabrics prepared with a solution of sal ammoniac, or phosphate of ammonia, may be placed in contact with ignited bodies without danger. They will carbonize, but not inflame. Solutions of alum, sea salt, &c., have been used for the same purpose. It is by a knowledge of this property of culinary salt, that jugglers are enabled to perform the common trick of burning a thread of cotton while supporting a ring or a key, without the latter falling to the ground. The cotton is reduced to a cinder, but, from the action of the salt, its fibres still retain sufficient tenacity to support a light weight.

CLOTH, RENOVATION OF. The article undergoes the process of scouring before described, and, after being well rinsed and drained, it is put on a board, and the threadbare parts rubbed with a half-worn hatter's card, filled with flocks, or with a teazle or a prickly thistle, until a nap is raised. It is next hung up to dry, the nap laid the right way with a hard brush, and finished as before. When the cloth is much faded, it is usual to give it a "dip," as it is called, or to pass it through a dye-bath, to freshen up the color.

CLOTHES, BRUSHING AND PRESERVATION OF. If very dusty, hang them on a horse or line, and beat them with a cane; then lay them on a clean board or table, and well brush them, first with a stiff brush, to remove the spots of mud and the coarsest of the dirt, and next with a softer one, to remove the dust and to lay the nap properly. If clothes be wet and spotted with dirt, dry them before brushing, and then rub out the spots with the hands. The hard brush should be used as little as possible, and then with a light hand, as it will, if roughly and constantly employed, soon render the cloth threadbare. Should there be spots of tallow-grease on the clothes, take it off with the nail, or, if that cannot be done, have a hot iron with some thick brown paper, lay the paper on the part where the grease is, then put the iron upon the spot; if the grease comes through the paper, put on another piece, till it ceases to soil it.

After the clothes are brushed, they should be hung up in a clean place, free from dust, if wanted for immediate use; but if intended to remain unused for some time, they should be placed away on the shelves of the clothes' closet or wardrobe. The latter should always be in the driest situation possible, as if the clothes be exposed to the least damp, they not only acquire an unpleasant smell, but gradually become rotten.

CLOVES. The flower buds of the eugenia caryophyllata, dried and smoked. It is a common practice to adulterate this spice in the same manner as cinchona bark. Cloves from which the oil has been distilled are dried and rubbed between the hands, previously moistened with a little sweet oil, to brighten their color, after which they are mixed up with fresh spice for sale.

COACH ACCIDENTS. "Should the horses run off, in defiance of all restraint, while you are in a coach, sit perfectly still, and in anticipation of the possible overturn, keep your legs and arms from straggling. Sit easily and compactly, so that, when upset, you will gently roll over in the direction you are thrown. We have seen ladies in these circumstances scream wildly, and throw their arms out of the windows, thus exposing themselves to the chance of broken limbs. If run away with in a gig, either sit still collectedly, or drop out at the back, so as to fall on your hands. Never jump from a rapidly-moving vehicle, unless (supposing it impossible to slip down behind) you see a precipice in front, in which case any risk of personal damage is preferable to remaining still. The Duke of Orleans lost his life by neglecting these simple precautions."

COAK. *Syn.* COKE. CHARRED COAL. MINERAL CHARCOAL. Carbonized coal. The principle of its manufacture is similar to that of charcoal. There are three varieties of coak, viz.

I. (*Kiln-made coak. Stifled coak.*) Made by burning the coal in a pile, kiln, or stove. It has a dull black color, and produces an intense heat when used as fuel. The coal is frequently burnt in a series of shallow stoves, with as little access of air as will support the combustion, and the smoke conducted through proper horizontal tunnels to a capacious brick chamber, 100 yards or more in length, kept as cool as possible by a stream of water passing over its roof, or by a shallow pond resting on it. Here the bituminous vapors are condensed in the form of tar, along with a considerable quantity of crude ammoniacal salt. Common coal yields about 3§ of tar when treated in this way, but some strong bituminous coal will give $\frac{1}{7}$ or $\frac{1}{8}$ of its weight. This tar, when inspissated, gives 75§ of pitch, and 20 to 24§ of a crude species of naphtha, that is excellent for out-door painting. The ammonia is made into sal ammoniac. The *screenings*, or dust-coal, separated from the better kinds of bituminous coal, is the sort commonly used for making coak in ovens.

II. (*Gas coak. Distilled coak.*) The cinder left in the retorts after the gas has been distilled off. Its color is gray, and it only produces a weak heat in burning, not sufficient to smelt iron.

III. (*Slate coak. Carbon mineral.*) From bituminous slate, burned in covered iron pots, in a similar way to that adopted for making bone-black. Also burnt in piles. It is black and friable. Used to clarify liquids, but vastly inferior to bone-black, and does not abstract the lime from sirups.

COBALT. *Syn.* REGULUS OF COBALT. A metal discovered by Brandt, in 1733. It is found in ores, associated with arsenic and other metals, and is constantly present in meteoric iron.

Prep. Dissolve oxide of cobalt in muriatic acid, and pass sulphureted hydrogen gas through the solution, until all the arsenic is thrown down; filter and boil with a little nitric acid, then add an ex-

tion with a weak solution of carbonate of potassa, repose, and decantation. It is lighter than water, boils at 425° Fahr., and has an odor resembling an empty wine cask or bottle that has been exposed to the air for some time. As obtained by distillation, it is united with a little œnanthic acid. 2200 imperial gallons of wine (about 35 hogsheads) only yielded 2½ lbs. of the mixed oil.

ETHER, OXALIC. *Syn.* OXALATE OF OXIDE OF ETHULE. NEUTRAL DO. A colorless oily liquid, slightly heavier than water, boiling at 370° Fahr., and having an aromatic smell. It was discovered by Thenard.

Prep. Binoxalate of potassa, and alcohol of 90%, of each 4 parts; oil of vitriol 5 parts; mix in a glass retort and distil with a quick fire; as soon as the product becomes turbid when mixed with water, change the receiver, agitate the subsequent product with 4 or 5 times its weight of water, and repeat the agitation with fresh water until the ether becomes neutral to test paper; then rectify it in a dry retort that it will about nine-tenths fill, and as soon as the boiling proceeds smoothly, instead of by jerks, change the receiver; the remaining product will be pure anhydrous oxalic ether. (Ettling.) See ETHERS, ORGANIC.

ETHER, PHOSPHORATED. *Syn.* ÆTHER PHOSPHORATUS. *Prep.* (P. Cod.) Phosphorus, cut small, 1 part; ether 50 parts; digest with occasional agitation for 1 month, and decant the clear.

ETHER, SULFURIQUE IODURE. *Syn.* ETHEREAL TINCTURE OF IODINE. *Prep.* Iodine 40 grs.; sulphuric ether ℥j; dissolve. *Dose.* 5 to 10 drops, where the use of iodine is indicated.

ETHER, SULFURIQUE AVEC LE DEUTOIODURE DE MERCURE. *Syn.* ETHEREAL TINCTURE OF BINIODIDE OF MERCURY. *Prep.* Biniodide of mercury 16 grs.; sulphuric ether ℥iss; dissolve. *Dose.* 5 to 12 drops.

ETHERS, ORGANIC. The preparation of some of the organic ethers has been found to be attended with considerable difficulty, and hence have arisen various contrivances to induce the organic acids to combine with the ethereal base. Among the methods generally adopted until lately, may be mentioned the admixture of a salt of the organic acid with alcohol, to which some strong inorganic acid is added, when the acid of the salt being liberated in the nascent state, it enters into a new combination, forming ether. In this way acetic and oxalic ethers are commonly prepared. Or the organic acid being mixed with alcohol, sulphuric or hydrochloric acid is added, by which an organic ether is produced. Benzoic ether may be taken as an instance of this mode of operating. Ethers have also been formed by the simple distillation of some of the organic acids with alcohol, but this method is usually tedious, and requires the repeated return of the products of distillation into the retort, as well as considerable time for its performance, to which several other objections may be added. More recently it has been shown that when the organic acids are heated nearly to their point of decomposition, and alcohol is gradually and cautiously dropped on them, ethers of those acids are readily formed. In this way many of the acids which are wholly or partly volatile—as the oxalic, benzoic, and succinic acids,—yield large quantities of ether. (Gaultier de Claubry.) This method is applicable to most acids that do not suffer decomposition at a low temperature, but in other cases the product would be vitiated and uncertain. Thus, citric acid under this treatment might yield citric, itaconic, citraconic, or aconitic ether, or a mixture of two or more of them, and this in a way entirely beyond the power of the operator to influence. Another method recommended, and very suitable to the preparation of the ethers of the fatty acids, is—to dissolve the organic acid in alcohol, and to pass a current of muriatic acid gas through the solution. A still simpler plan, and which appears likely to supersede most others, at least in the majority of cases, is to mix equal parts of alcohol and the organic acid, with ¼th or ⅛th of oil of vitriol, and to place it in a flask or digester, fitted with a cork, through which passes an upright thin glass tube, 5 or 6 feet long, and after luting the joint quite securely, to submit the mixture to gentle ebullition in a sand-bath, or over a spirit lamp for several hours. In this way the spirituous and ethereal vapors are condensed in the cool portions of the tube, and fall back again into the matrass, by which means no loss of either can possibly occur. A Liebig's refrigerator *reversed* may also be used for this purpose. (See ETHER.) By this method some ethers may be readily formed that can scarcely be obtained pure in the usual way. Thus mucic ether may be obtained by this process, which will become perfectly white by crystallization, while by Malagutti's method, the product is quite black, and is purified with difficulty. One or other of the above plans may be adopted for the preparation of those ethers for which formulæ are not inserted in this volume.

ETHERIN. A name applied by some chemists to a hydrocarbon, assumed to be the base of ether. Its atomic constitution, according to this hypothesis, is 4 equivalents each of hydrogen and carbon.

ETHERINE. *Syn.* CAMPHOR OF OIL OF WINE. A peculiar substance obtained by exposing etherole for a long time to a low temperature. It forms brilliant prisms and plates, and is tasteless, soluble in alcohol and ether, fuses at 230°, boils at 500°, and is a little lighter than water. The crystals are purified by pressure between the folds of bibulous paper, solution in ether, and evaporation.

ETHEROLE. *Syn.* LIGHT OIL OF WINE. A hydrocarbon discovered by Hennel. It is prepared by gently heating ethereal oil with water, separating the supernatant light oil, and washing this with water till it becomes quite neutral, after which it is dried by means of chloride of calcium. Etherole is a colorless oily liquid, lighter than water, boiling at 536°, and soluble in absolute alcohol and ether.

ETHIOPS. (See ÆTHIOPS.)

ETHIOPS, MARTIAL. *Syn.* ÆTHIOPS MARTIALIS. Oxide of iron prepared by keeping iron filings under water, and occasionally shaking them. It must be washed with water, and dried as quickly as possible to prevent its rusting. It was formerly much esteemed as a tonic.

ETHIOP'S MINERAL, (TYSON'S.) *Prep.* Oxide of mercury, (prepared by decomposing calomel with an equivalent proportion of liquor of potassa, to which a little liquor of ammonia has been

the animal matter and an acid, from which it may be nearly purified by solution in liquid ammonia, and precipitations by acetic acid, mixed with alcohol. Cochenillin may also be prepared by evaporating a watery infusion of cochineal to the consistence of sirup, dissolving this in proof spirit, filtering, again evaporating, and dissolving the residuum in liquid ammonia as before. It is turned orange by acids, and violet by alkalis. It has been obtained under the form of reddish-purple crystalline grains.

COCKLE POWDER. Cockles pulped through a sieve, made into a paste with flour, and a little salt, and then rolled out into thin pieces and dried. It is next reduced to powder, sifted, and packed in well-corked bottles. *Use.* To make sauce, (about ½ oz. to ½ pint.)

COCOA. I. The roasted husks of the cacao, or chocolate bean, reduced to powder by grinding.

II. The cake left after expressing the oil from the beans.

COCOA, PATENT. The cacao nut roasted and ground, (including the husks.)

COCOA, FLAKED. Ground cocoa strongly compressed, and flaked with a sharp knife or machine.

COCOA, SOLUBLE. Cocoa ground to a very fine powder, and mixed with sugar. It is thus rendered miscible with boiling water.

Remarks. Cocoa forms a very wholesome beverage, especially for breakfast. Much of the cheap stuff sold under this name is very inferior, being made with damaged nuts that have been pressed for the oil, mixed with potato flour, mutton suet, &c. Trash of this kind is frequently ticketed in the shop windows of London at 6*d.* to 8*d.* a pound. (See CHOCOLATE.) The nut of the palma cocos is commonly confounded with that of the theobroma cacao. The latter is the small chocolate bean, while the former is the large nut, filled with a refreshing milky juice.

COD. This excellent fish is in season from the beginning of October to the end of April. It should be chosen by the redness of the gills, freshness of the eyes, and the whiteness and firmness of the flesh. The best fish are very thick about the neck. It is generally cooked by boiling, but is sometimes baked, or cut into slices and broiled or fried. Cod's head and shoulders, with oyster sauce, is a favorite dish. Shrimp and anchovy sauce are also good additions. The flesh of the cod is often split and dried, (dried cod,) or salted. The fish so largely imported from Newfoundland are cod, beheaded, split open, gutted and salted. They are caught by millions on the "Grand Bank." Cod-sounds are pickled in brine and also made into isinglass. The liver is boiled for its oil, and the spawn made into caviare.

CODEIA. *Syn.* CODEINE. An alkaloid discovered by Robiquet associated with morphia.

Prep. Dissolve commercial hydro-chlorate of morphia in water, precipitate with ammonia, evaporate and crystallize. The product is a double salt of morphia and codeine, and when digested with warm liquor of potassa gives up its morphia. It may be further purified by solution in ether, and by the addition of a little water and spontaneous evaporation may be obtained quite pure and in a crystalline state.

Prop. Soluble in alcohol, ether, and water. Its solution in the latter, by slow evaporation, yields large transparent octohedrons. With the acids it forms crystallizable salts. These possess the singular property of producing a general and violent itching of the surface of the body when administered internally. The same symptoms frequently follow the exhibition of opium and muriate of morphia, and are referred to the presence of a salt of codeia. (Gregory.) The commercial muriate frequently contains 3 to 4§ of codeia.

Char. and Tests. It is distinguished from *morphia* by not becoming blue on the addition of the sesquichloride of iron, nor turning red with nitric acid, and by not being precipitated by ammonia, when dissolved in muriatic acid and mixed with a large quantity of water. Unlike morphia, it is insoluble in liquor of potassa and is soluble in ether. The salts of codeia may also be known by tincture of galls throwing down a copious precipitate from their solutions, but this does not occur in the salts of morphia. It may be distinguished from meconine by its aqueous solution showing an alkaline reaction with test paper.

COFFEE. The berry of the coffæa Arabica. II. A decoction or infusion prepared therefrom.

Qual. Coffee promotes digestion and exhilarates the spirits, and when strong generally occasions watchfulness, but in some phlegmatic constitutions induces sleep. Drunk in moderation, especially if combined with sugar and milk, it is perhaps the most wholesome beverage known. The various qualities that have been ascribed to it by some persons, such as dispelling or causing flatulency, removing dizziness of the head, attenuating the blood, causing biliousness, &c., appear to be wholly imaginary. In a medical point of view it has been regarded as diuretic, sedative, and a corrector of opium. It should be given as medicine in a strong infusion, and is best cold. In spasmodic asthma it has been particularly serviceable; and it has been recommended in gangrene of the extremities arising from hard drinking. (See CAFFEIN.)

Pur. The most common adulteration of ground coffee is chicory, which is added not only to cheapen the article, but to improve the flavor of damaged or inferior berries. This adulteration may be readily detected by shaking a spoonful of the suspected coffee with a wine-glassful of water, when, if it be pure, it will swim and scarcely color the liquid, but if chicory be present, it will sink to the bottom, and the water will be tinged of a deep red. *Roasted corn* is another common adulteration. This may be detected by the cold decoction striking a blue color with tincture of iodine.

COFFEE CREAM. *Prep.* Add a teacupful of very clear strong coffee to 1 pint each of clarified calf's feet jelly and good cream; sweeten with lump sugar, give it one boil up, and pour it into shapes or glasses, when nearly cool. The calf's feet jelly should be thick enough to render the whole lightly solid but not stiff.

COFFEE DROPS. *Prep.* Make an infusion with 1 oz. of coffee, clarify it, and moisten 1 lb. of sugar therewith, in the way directed for confectionary drops.

COFFEE, ESSENCE OF. A concentrated infusion of coffee prepared by percolation, to which

tained by expression. The substances are first bruised in a marble mortar, or, on the large scale, in a mill, and immediately submitted to the press, to prevent them passing into the state of fermentation, which would injure the quality of the product. Fruits which contain highly-flavored seeds, or which have rinds containing essential oil, should be deprived of them before pressing. The subacid fruits should also be allowed to lie together for some days before being pressed, as the quantity and quality of the product are thereby increased. The fluid matter absorbed by the ingredients employed in the preparation of tinctures, infusions, decoctions, extracts, &c., is generally obtained by powerful pressure. Expression is also frequently employed for the purpose of obtaining solids in a state of purity, as in the expulsion of oleine from stearine, and water from the bicarbonate of soda. On the small scale, the common screw-press, or one of like construction, is usually employed; but the power thus obtained is insufficient to expel the *whole* of a fluid diffused through the pores of a solid. Hence has arisen the use of the hydraulic press, which is alone employed on the large scale. In all these cases, the substances are placed in bags made of hair-cloth, or coarse canvass, previously to their being submitted to pressure.

EXSICCATION. *Syn.* Exsiccatio, (*Lat.*, from *exsicco*, to dry up.) The evaporation of the aqueous portion of solid bodies. In Chemistry and Pharmacy, this term is commonly applied to the operation by which plants and chemical preparations are deprived of their humidity. This is done by exposure to the sun, a current of dry air, an atmosphere rendered artificially dry by sulphuric acid, or by the direct application of heat by means of a water-bath, a sand-bath, or a common fire.

EXTRACTS. *Syn.* Extraits, (*Fr.*) Extracten, (*Ger.*) Extracta, (*Lat.*, from *extraho*, to draw out.) In Chemistry, the residuum from the evaporation of aqueous decoctions, or infusions of vegetable matter. In Pharmacy, preparations obtained by evaporating the expressed juices, or the decoctions, infusions, or tinctures, of vegetable substances, until a mass, of a solid or semi-solid consistence, is formed. Extracts vary in their nature and composition with the substances from which they are prepared, and the fluids employed as solvents. When water is used for making the solution, the extract will usually consist of gum, starch, sugar, albumen, and saline and other matter, along with a peculiar vegetable principle, which, from its occurrence in most plants, has received the name of extractive. This substance was discovered by Fourcroy, and presumed by him to be the common basis of *all* extracts; but it has since been proved by Chevreul, and several other chemists, to be a heterogeneous compound, varying in composition with the plant from which it is extracted. This substance has a brown color, speedily putrefies, and becomes oxidized, and is rendered insoluble by long exposure to air, and by repeated solutions and evaporations. In its unaltered state it is soluble in water, and in alcohol, and is precipitated from its solutions by the acids and metallic oxides. With alumina it forms the basis of several brown dyes. In the preparation of the greater number of extracts, water is employed as the menstruum, and these preparations are called, by way of distinction, "*watery extracts.*" When spirit is employed as the solvent, the extract may contain most of the substances above enumerated, except gum, which is insoluble in strong spirit. Besides these, spirit dissolves out many substances which are either wholly or nearly insoluble in water, as resins, essential oils, and the proximate principles of vegetables. Extracts prepared with alcohol, either alone, or diluted with water, are termed "*spirituous extracts,*" and, with scarcely an exception, are considerably more powerful than the *aqueous extracts* of the same vegetables. In some cases, dilute acid, (the acetic,) or acidulated water, is employed as the menstruum, and such preparations are hence called "*acetic extracts.*" The extracts of aconite, hemlock, henbane, stramonium, and colchicum, as well as of all other plants containing alkaloids, possess greater activity when prepared with vinegar than with water. Thus, a quantity of either the alcoholic or acetic extract of colchicum, equal to the common dose of the *aqueous extract*, would most probably produce death. Still more active extracts may be obtained by a combination of the last two menstrua. According to Ferrari, plants treated with rectified spirit of wine, mixed with one-thirty-sixth part of pyroligneous (acetic) acid, yield extracts of remarkable activity. (Prov Med. Jour., 1843.) To the preceding may be added, that the term *simple* extract is applied to one prepared from a single plant, or vegetable substance, and the term *compound* extract to one prepared from *two* or *more* of such substances.

The above are the principal varieties of extracts employed in British Pharmacy, all of which are classed under the general head *Extracta*, (extracts,) in the London Pharmacopœia; but on the Continent, ether is sometimes used as the menstruum for the active principles of certain substances, as cantharides, cubebs, sem. cinæ, &c.

Of all the foreign Pharmacopœias, that of Baden is most prolific of extracts; its pages contain directions for 58 or 60 of these preparations, of which the following is a brief notice:—

I. Watery Extracts. *a.* (*By displacement with cold water.*) Ext. absinthii; cardui benedicti; centaurii min.; chamomillæ; chinæ fuscæ, (cinchonæ;) chinæ regiæ; dulcamaræ; fumariæ; gentianæ; glycyrrhizæ; graminis ord., (liquid and solid;) ligni campech.; marrubii alb.; millefolii; rhataniæ; rad. saponar; taraxaci, (ordinary and fluid;) tormentillæ; trifolii fibr.

β. (*By the ordinary method of maceration.*) Ext. aloes; myrrhæ; opii; scillæ, valerianæ; chinæ fuscæ.

II. Spirituous Extracts. *a.* (*Prepared with spirit of sp. gr.* 0·944, *by* 24 *hours' maceration, or by the method of displacement.*) Ext. cort. aurantii; angelicæ; rad. arnicæ; calami; calendulæ, (marygold;) cascarillæ; calumbæ; colocynth.; inulæ; hellebori nigri; levistici, (Lovage;) quassiæ; rhæi.

β. (*Prepared in a similar way to the last with spirit of sp. gr.* 0·841.) Ext. aconiti; belladonnæ; chelidonii maj., (great celandine;) conii mac.; digitalis; gratiolæ, (hedge hyssop;) hyoscyami; lactucæ virosæ; pulsatillæ, (Pasque flower;) herb. taxi baccatæ, (yew;) rad. artemisiæ, nucis vomicæ.

at a very low temperature, (in vacuo if possible,) until the mixture acquires the consistence of a sirup, paste, or candy. (The latter may be powdered.)

COFFEE, SUBSTITUTES FOR. These are numerous, but the principal are the following:

I. (*Rye coffee. Dillenius's ditto. Hunt's breakfast-powder.*) Rye, roasted along with a little butter, and ground to powder. A good substitute.

II. (*German coffee. Succory ditto. Chicory ditto.*) From succory, as above. *Used* either for or mixed with foreign coffee. The most common adulteration of the latter.

III. (*Rice coffee.*) From rice, as above. A good substitute.

IV. (*Currant coffee.*) From the seeds washed out of the cake left in making currant wine.

V. (*Gooseberry coffee.*) From gooseberry seeds, as the last.

VI. (*Holly coffee.*) From the berries.

VII. (*Egyptian coffee.*) From chickpeas.

VIII. (*Rosetta coffee.*) From fenugreek seeds moistened with lemon juice.

IX. (*Corsican coffee.*) From the seeds of the knee-holly.

X. (*Sassafras coffee.*) From the fruit or nut of the sassafras tree, or from the wood cut into chips. Very wholesome. Much recommended in skin diseases, &c.

XI. (*Raspings.*) The raspings of the crust of loaves, procured at the baker's. Equal to rye coffee.

XII. (*Beech-mast coffee.*) From beech-mast or nuts. Very wholesome.

XIII. (*Acorn coffee.*) From acorns, deprived of their shells, husked, dried, and roasted. A good substitute.

XIV. (*Beet-root coffee.*) From the yellow beet-root, sliced, dried in a kiln or oven, and ground with a little foreign coffee. A good substitute.

XV. (*Bean coffee.*) Horse-beans roasted along with a little honey or sugar. When removed from the fire, a small quantity of cassia-buds is frequently added, and the whole is stirred until cold. Said to be a good substitute.

XVI. (*Almond coffee.*) Rye or wheat roasted along with a few almonds. A very small quantity of cassia-buds improves it. A good substitute.

COINS, IMPRESSIONS FROM. A very easy and elegant way of taking the impressions of medals and coins, not generally known, is as follows: Melt a little isinglass glue with brandy, and pour it thinly over the medal, so as to cover its whole surface; let it remain on for a day or two, till it has thoroughly dried and hardened, and then take it off, when it will be fine, clear, and as hard as a piece of Muscovy glass, and will have a very elegant impression of the coin. It will also resist the effects of damp air, which occasions all other kinds of glue to soften and bend if not prepared in this way. (Shaw.) If the wrong side of the isinglass be breathed on, and gold-leaf applied, it will adhere, and be seen on the other side, producing a very pleasing effect. Isinglass glue, made with water alone, will do *nearly* as well as if brandy be used.

Remarks. Medals may also be copied by surrounding them with a hoop of paper, and pouring on them plaster of Paris (mixed with water to the consistence of cream) to the depth of about ¼ an inch. Melted wax, stearine, fusible metal, or any similar material, may be used in the same way. If it be desired to copy the metal in copper, a mould should be first formed in the above manner, and the metal deposited on its surface by the agency of electricity. (See ELECTROTYPE.)

COLCHICINE. *Syn.* COLCHICINA. COLCHIA. A peculiar principle discovered by Gieger and Hesse in the seeds of the colchicum autumnale, or common meadow saffron. It also exists in the cormi or bulbs.

Prep. Macerate the crushed seeds in boiling alcohol, add hydrate of magnesia to throw down the alkaloid, digest the precipitate in boiling alcohol, and filter. By cautious evaporation colchicine will be deposited. It may be purified by re-solution.

Prop., &c. Odorless; tastes bitter; forms salts with the acids. It is very poisonous. One-tenth of a grain, dissolved in spirit, killed a cat in 12 hours. It differs from veratrine in being soluble in water, crystalline, and the non-production of sneezing when applied to the nose. Strong oil of vitriol turns this alkaloid of a yellowish brown; nitric acid of a deep violet, passing into indigo blue, green, and yellow.

COLCHICUM, POWDER OF. I. (*Collier.*) Seeds of colchicum 2 grs.; rhubarb 6 grs.; magnesia 10 grs.; mix for 1 powder, to be taken every six hours in acute rheumatism, inflammatory gout, &c., washing it down with a glass of Seltzer water, during high febrile action only.

II. (*Collier.*) Seeds of colchicum 3 grs.; muriate of ammonia 5 grs.; for 1 powder. For checking a paroxysm of gout, but its use requires caution. "After all that has been said respecting colchicum in gout, and admitting that it rarely fails to allay pain and check a paroxysm, I would record my opinion that he who would wish to arrive at a good old age, should eschew it as an ordinary remedy, and consider that he is drawing on his constitution for a temporary relief, with a certainty of becoming prematurely bankrupt in his vital energies."

COINDET'S PILLS. *Prep.* Protiodide of mercury 1 gr.; extract of liquorice 20 grs.; mix, and divide into 8 pills. *Dose.* 2 to 4 twice or thrice daily, as an alterative in scrofulous tumors, ulcers, &c.

COLD. When the body of an animal is immersed in an atmosphere at a temperature below the healthy standard, a sensation of coldness is experienced, produced by the passage of the caloric or heat of the body into the colder medium. If this withdrawal of caloric exceed the quantity produced by the vital system, the temperature of the body decreases, until it sinks below the point at which the functions of life can be performed. This declination is gradual; the extreme sensation of coldness changes into a disinclination for voluntary motion; next comes on drowsiness, followed by numbness and insensibility. In this state, if the sufferer be not rescued, and remedial measures had recourse to, death must rapidly follow.

Prevention of the effects of excessive cold.—The extremities of the body first suffer from the action of cold, owing to the circulation of the blood being less vigorous in those parts; they should,

therefore, be properly protected from its action. Woollen stockings or socks, with good shoes or boots, should be worn on the feet, and the body should be clad in thick woollen fabrics, proportioned to the inclemency of the weather, and the habits of the wearer. The circulation of the blood should be promoted by active exercise, and any disposition to sleep shaken off by increased bodily exertion. If the situation be such that exercise cannot be had recourse to, drowsiness is more likely to be experienced, and must be warded off, if possible, by keeping the mind incessantly and actively engaged. The principal endeavor should be to keep the extremities warm, as, if this be accomplished, no danger need be feared. In travelling by coach or on horseback, recourse may be had to hay and straw, which may be thrown over the feet and legs, and will materially ward off the effects of the weather.

Remedial measures for asphyxia produced by intense cold.—The patient should be laid in a room remote from the fire, and bathed with cold salt and water, after which the body should be wiped dry, and friction applied by the hands of the attendants, (warmed;) as many operating at once as can conveniently do so. Gentle stimulants should be administered by the mouth, and the bowels excited by some mild stimulating clyster. The lungs should also be inflated. (See ASPHYXIA.) As soon as symptoms of returning animation are evinced, and the breathing and circulation restored, the patient should be laid in a bed between blankets, and a little wine and water administered, and perspiration promoted by heaping an ample quantity of clothing on the bed. Should the patient have suffered from hunger as well as cold, the appetite may be appeased by the administration of a limited quantity of light food, taking especial care to avoid excess, or any thing indigestible or exciting.

COLIC. (From κωλον, the colon, the supposed seat of the disease.) The colic or bellyache. This name is commonly given to all severe griping abdominal pains, whatever may be the cause. This disease has been distinguished by nosologists into several varieties, as follows:—

I. (*The spasmodic colic.*) This kind is marked by a fluctuating pain about the navel, which goes away and returns by starts, often leaving the patient for some time. The belly is usually soft, and the intestines may often be felt in lumps, which move about under the hand, or wholly vanish for a time. It is unaccompanied by flatulency. *The remedies* are, warm fomentations, warm clysters, and carminatives, accompanied by small doses of camphor and opium.

II. (*The stercoraceous colic.*) This is marked by severe griping pains and constipation of the bowels. *The remedies* are powerful cathartics, as full doses of calomel, aloes, colocynth, jalap, &c., followed by purgative salts, as sulphate of magnesia or soda.

III. (*Bilious colic.*) In this variety the pain is intermittent and transient, accompanied by constipation, nausea, and vomiting. The fæces, if any, are bilious, dark-colored, and offensive. *The remedies* are, a full dose of blue pill, calomel, colocynth, or aloes, followed by a sufficient quantity of epsom or glauber salts. Warm fomentations are also serviceable.

IV. (*Flatulent colic.*) Marked by constipation and the irregular distension of the bowels by gas, accompanied by a rumbling noise, &c. It is commonly produced by the use of flatulent vegetables and slops. *The remedies* are, a full dose of tincture of rhubarb combined with a few drops of essence of peppermint. If this does not afford relief, a pill made of 3 grs. of blue pill and 2 grs. of compound extract of colocynth, may be taken, washed down with a glass of any cordial water, as peppermint, cinnamon, or caraway. If the pain be extreme, warm fomentations to the belly, or a carminative clyster may be adopted.

V. (*Accidental colic.*) Produced by improper food and poisons. The treatment differs but little from the last variety.

VI. (*Colica pictonum. Devonshire colic. Plumber's do. Painter's do. Lead do.*) The dry bellyache. This species of colic is marked by obstinate costiveness, acrid bilious vomitings, violent pains about the region of the navel, convulsive spasms in the intestines, and a tendency to paralysis in the extremities. It is most prevalent in the cider counties, and among persons exposed to the fumes of lead. *The remedies* are the same as for the spasmodic variety. Should these fail, after the bowels have been thoroughly evacuated, small doses of camphor and opium may be administered. Mr. Benson, the managing director of the British Whitelead Works at Birmingham, strongly recommends the use of sulphuric acid; he says: "I met with a statement some time since that sulphuric lemonade has been successfully used at a white lead manufactory in France as a preventive of the injurious effects of white lead; and it occurred to me that by adding *sulphuric acid* to the treacle-beer then used by our people, its supposed efficacy might be tested. This idea was carried into effect in the summer of 1841, and the results have proved most gratifying, as, although during several weeks after the addition of the sulphuric acid to the treacle beverage, little advantage seemed to be derived, yet the cases of lead colic became gradually less frequent, and since October of that year, or during a period of fifteen months, not a single case of lead colic has occurred among the people." (Lancet.)

The following is Mr. Benson's form for his treacle or sulphuric beer:—Take of treacle 15 lbs.; bruised ginger ½ lb.; water 12 gallons; yeast 1 quart; bicarbonate of soda 1½ oz.; sulphuric acid (oil of vitriol) 1½ oz. by weight: boil the ginger in 2 gallons of water; add the treacle and the remainder of the water, hot; when nearly cold transfer it to a cask, and add the yeast to cause fermentation; when this has nearly ceased, add the sulphuric acid, previously diluted with eight times its quantity of water, and then add the bicarbonate of soda, dissolved in one quart of water. Close up the cask, and in three or four days the beer will be fit for use. As acetous fermentation speedily takes place, particularly in hot weather, new supplies should be prepared as required.

COLOCYNTHINE. *Syn.* COLOCYNTHITE. COLOCYNTHIUM. The purgative bitter principle of the colocynth.

Prep. Digest the aqueous extract or the pulp of colocynth in alcohol, filter and evaporate the tincture. The residuum is colocynthine combined with acetate of potassa. By agitation with a *little*

ater the latter is removed. It may be purified by re-solution in alcohol, and evaporation.

Prop. A yellowish brown translucent resinous substance, very soluble in alcohol, less so in ether, and only slightly so in water. It is intensely bitter, and acts as a drastic purgative.

COLORING. *Syn.* BREWER'S COLORING, BRANDY DO. SPIRIT DO. ESSENTIA BINA. CARAMEL. *Prep.* Melt brown sugar in an iron vessel over the fire, until it grows black and bitter, stirring it well all the time, then make it into a sirup with water.

Remarks. Some use lime-water to dissolve the burnt sugar. Care must be taken not to overburn it, as a greater quantity is thereby rendered insoluble. The heat should not exceed 430°, nor be less than 400°. The process for nice experiments is best conducted in a bath of melted tin, to which a little bismuth has been added to reduce its melting point to about 435°; a little powdered resin or charcoal, or a little oil being put upon the surface of the metal to prevent oxidizement.

COLORS, COMPOUND. (IN DYEING.) The mixture of BLUE and YELLOW dyes produces *green;* RED and BLUE, *violet, purple, lilacs, &c.;* RED and YELLOW, *orange, cinnamon, &c.;* RED, YELLOW, and BLUE, *olives;* RED and BLUES, or GREEN or BLACK, *browns* of all shades; BLACK mixed with other dyes produces various shades of *brown* and olive, and when pale it constitutes *gray,* either by itself or the addition of a faint blue.

COLOMBIUM. A rare metal, discovered by Mr. Hatchet in 1801, in a black mineral belonging to the British Museum. Supposed to have been brought from America, hence the name. (See TANTALUM.)

COLUMBIC ACID. The preceding metal exists in its ores in the form of an acid, united to iron, manganese, or yttria. From these it may be obtained by fusion with 3 or 4 parts of potash, solution in water, and precipitation with an acid. It falls as a white powder or hydrate.

CONCENTRATION. (IN CHEMISTRY.) The volatilization of part of a liquid in order to increase the strength of the remainder. The operation can only be performed on solutions of substances of greater fixity than the menstrua in which they are dissolved. Many of the liquid acids, solutions of the alkalis, &c., are concentrated by distilling *off* their water.

(IN PHARMACY.) The term "concentrated" is very commonly applied to any liquid preparation possessing more than the usual strength. Thus we have "*concentrated*" *infusions, decoctions, liquors, solutions, tinctures,* and *essences,* most of which are made of 8 times the common strength. This is generally effected by using 8 times the usual quantity of the ingredients, with a given portion of the menstruum, and operating by digestion or percolation; the latter being generally adopted when the articles are bulky. When the menstruum is water, a little spirit is added to make the product keep.

CONCRETE. (IN ARCHITECTURE.) A compact mass, composed of pebbles, lime, and sand, employed in the foundations of buildings. The best proportions are 60 parts of coarse pebbles, 25 of rough sand, and 15 of lime.

CONDIMENTS. Substances taken with the food, to improve its flavor, or to render it more wholesome or digestible. The principal condiments are common salt, vinegar, lemon juice, spices, aromatic herbs, oil, butter, sugar, honey, and sauces. Most of these, in moderation, promote the appetite and digestion, but their excessive use tends to injure the stomach, and vitiate the gastric juice.

CONFECTIONS. (IN PHARMACY.) Medicines, usually pulverulent, mixed up to the consistence of a paste with powdered sugar, sirup, or honey. In the "London Pharmacopœia," both conserves and electuaries are included under this head, though there appears to be some little distinction between them. As remedial agents, the officinal confections possess but little value, and are chiefly useful as vehicles for the administration of more active medicines. In making confections, the sugar requires the same attention as for sirups. They should be kept in stone jars, covered with writing paper, and placed in a cool and dry situation. Without this precaution, they are apt to mould on the top. All the dry ingredients employed in making confections should be reduced to a very fine powder, and passed through a sieve not coarser than 80 holes to the inch.

CONFECTION OF ALMONDS. *Prep.* (*Confectio Amygdalæ,* P. L.) Sweet almonds ℥viii; white sugar ℥iv; powdered gum arabic ℥j. Macerate the almonds in *cold* water, then remove the skins, and beat them with the other ingredients until reduced to a smooth confection.

Use. To prepare milk of almonds. A little of this paste or powder, triturated with a sufficient portion of water, and strained through a piece of calico, forms emulsion of almonds.

CONFECTION OF ALKERMES. *Prep.* White sugar 1 lb.; rose-water ¼ pint; clarified juice of alkermes 3 lbs.; oil cinnamon 10 or 12 drops. Mix. It was formerly a common practice to add a little gold-leaf, rubbed small, so as to float about in it; also musk and ambergris.

CONFECTION OF ALUM. *Prep.* (*Conf. Aluminis,* St. B. H.) Alum in fine powder, 80 grs.; conserve of roses, enough to mix. *Use.* As an astringent.

CONFECTION, AROMATIC. *Syn.* SIR WALTER RALEIGH'S CORDIAL. CONFECTIO RALEIGHANA, (P. L. 1720.) DITTO CARDIACA, (P. L. 1745.) DITTO AROMATICA, (P. L. 1788, and since.) *Prep.* I. (P. L.) Nutmegs, cinnamon, and hay saffron, of each ℥ij; cloves ℥j; cardamoms ℥ss; prepared chalk ℥xvj; white sugar lbs. ij. Reduce the whole to a very fine powder, and keep it in a closed vessel. When wanted for use, mix it with water to the consistence of a confection.

Remarks. On the large scale the above form is seldom adhered to. Less saffron is commonly used, cassia is substituted for cinnamon, and, generally, the essential oil for the powder of cloves. Should there be any deficiency of color, this is brought up by a little tincture or infusion of turmeric. When a very smooth and fine powder is desired, it should be passed through a gauze sieve, not coarser than 80 holes to the inch, and precipitated chalk should be employed. The saffron should be dried with as little heat as possible, and care should be taken not to waste any in powdering. The following formula, which is employed by a large whole-

sale druggist in the city, produces an excellent article.

II. Hay saffron, cassia, and turmeric, of each 4 oz.; cardamoms 1 oz.; starch 8 oz.; precipitated chalk 2 lbs.; white sugar 4 lbs.; oil of nutmegs 2 drachms; oil of cloves 3 drachms. Reduce the dry ingredients to fine powder, and pass it through an 80 hole sieve, then add the oils, and after well mixing, pass it through a coarse sieve, (about 40 holes to the inch,) to ensure the whole being perfectly mixed.

The following form produces a powder possessing great depth and brilliancy of color.

III. Hay saffron 4 oz.; turmeric 3 oz.; powdered starch 8 oz.; precipitated chalk 2 lbs.; white sugar 4 lbs.; oils of cloves and cassia, of each 3 drachms; oil of nutmegs 2 drachms; essence of cardamoms 1 oz. *Proc.* Boil the saffron and turmeric in 1 gallon of water, placed in a bright copper pan, for 10 minutes, then, without straining, add the chalk, starch, and sugar; mix well, and continue stirring until the mixture becomes quite stiff, then break it up and dry it until fit for powdering. This must be performed in a water or steam bath. To the powder, passed through a fine sieve, as before, the oils and tincture must be added, and after being well mixed, and passed through a coarse sieve, it should be placed in a jar or bottle, and bunged up close.

Remarks. In the wholesale trade this article is kept under two forms: one in powder, as ordered by the College, and commonly called, for distinction sake, "*pulvis confectionis aromaticæ;*" the other mixed up ready for use. In preparing the latter, it is a common plan to make a strong infusion or decoction of the saffron, and to use it to mix up the other ingredients. Some persons follow the method described in the last formula, mixing up the powder to a proper consistence with water before adding the aromatics. When the price of *precipitated* chalk is an objection to its use, *prepared* chalk may be used instead. This confection is cordial, stimulant, and antacid. *Dose.* 10 to 60 grs.

CONFECTION OF BLACK PEPPER. *Syn.* WARD'S PASTE. *Prep.* (*Confectio Piperis Nigri*, P. L.) Black pepper and elecampane root, of each lb. j; fennel seed lb. iij; honey and white sugar, of each lb. ij; mix.

Remarks. The common practice is to keep the dry ingredients ready mixed in a bottle, and only to add the honey as wanted. The proportions are 2 parts of the latter to 7 of the mixture. The *dose* is 1 to 2 drachms 2 or 3 times a-day, in piles, fistula, &c. It should be persevered in for 2, 3, or 4 months, (Sir B. Brodie;) and as it is apt to accumulate in the bowels, its use should be accompanied by mild aperients. (Pereira.)

CONFECTIONS OF CASSIA. *Syn.* ELECTUARIUM CASSIÆ, (P. L. 1788.) *Prep.* (*Confectio Cassiæ*, P. L.) Fresh cassia pulp lb. ss.; manna ℥ij; tamarind pulp ℥j; sirup of roses f℥viij. Bruise the manna and dissolve it in the sirup, then add the pulps and evaporate to a proper consistence.

CONFECTION OF HEMLOCK. (Dr. Osborne.) *Prep.* Fresh leaves of hemlock and moist sugar equal parts; beat them to a confection in a mortar.

CONFECTION OF OPIUM. *Syn.* PHILONIUM ROMANUM, (P. L. 1720.) DITTO LONDINENSE, (P. L. 1745.) CONFECTIO OPIATA, (P. L. 1788.) DITTO OPII, (P. L. 1809, and since.) *Prep.* (P. L.) Powdered opium ʒvj; long pepper ℥j; ginger ℥ij; caraways ℥iij; tragacanth ʒij; all in fine powder; sirup f℥xvj. Mix.

Use and Dose. This confection is intended as a substitute for the *mithridate* and *theriaca* of the old Pharmacopœia. It is stimulant and narcotic, and is given in flatulent colic and diarrhœa unaccompanied by fever. The dose is from 15 to 50 grs.

CONFECTION OF ORANGE PEEL. *Syn.* CONSERVA FLAVEDINIS CORTICUM AURANTIORUM, (P. L. 1720 and 1745.) DITTO CORTICIS EXTERIORIS AURANTII HISPALENSIS, (P. L. 1788.) DITTO AURANTIORUM, (P. L. 1824.) DITTO AURANTII, (P. L. 1809 and 1836.) *Prep.* (P. L.) The external rind of the fresh orange, separated by rasping, lb. j; white sugar lb. iij. Beat the rind in a stone mortar with a wooden pestle, then add the powdered sugar, and beat the mixture until the two are perfectly incorporated.

Remarks. This confection is tonic and stomachic, and is principally used as a vehicle for the exhibition of tonic powders.

CONFECTION OF PEPPERMINT. *Prep.* Green peppermint 4 oz.; powdered white sugar 12 oz.; beat them together as last.

Use. Anti-emetic and flatulent. Given in colic, &c., in the form of a bolus, or made into a mixture.

CONFECTION OF THE DOG ROSE. *Syn.* CONFECTION OF HIPS. CONSERVA FRUCTUS CYNOSBATI, (P. L. 1720 and 1745.) DITTO CYNOSBATI, (P. L. 1788.) DITTO ROSÆ CANINÆ, (P. L. 1809, and since.) *Prep.* (P. L.) Pulp of the dog rose lb. j; powdered refined sugar ℥xx; mix by a gentle heat in an earthen vessel.

II. Pulped hips 2 cwt.; fine white sugar 2½ cwt.; incorporate them without applying heat.

Remarks. Both this and the following confection has a brighter color, if made without heat, or touching metallic vessels. On the small scale it is made by beating the ingredients together in a marble mortar, but in large quantities by grinding in a mill. It is slightly laxative, and is principally used for forming pills. It candies by keeping.

CONFECTION OF THE RED ROSE. *Syn.* CONSERVA ROSARUM RUBRARUM, (P. L. 1745.) DITTO ROSÆ, (P. L. 1788.) DITTO ROSÆ GALLICÆ, (P. L. 1809 and 1824.) CONFECTIO ROSÆ GALLICÆ, (P. L. 1836.) *Prep.* (P. L.) Petals of the red rose lb. j; refined sugar lb. iij; beat the petals in a stone mortar, then add the sugar, and again beat until thoroughly incorporated.

Remarks. On the large scale this is prepared like the confection of hips. It is astringent and tonic, and principally used for forming pills. If taken alone, the dose is 1 to 2 drachms.

CONFECTION OF RUE. *Syn.* ELECTUARIUM E BOCCIS LAURI, (P. L. 1720, 1745.) CONFECTIO RUTÆ, (P. L. 1809, and since.) *Prep.* (P. L.) Dried rue, caraway, and laurel berries, of each ℥iss; sagapenum (true) ℥ss; black pepper ʒij; honey ℥xvj. Reduce the dry ingredients to very fine powder, and when wanted for use, make them into a confection with the honey.

Use, &c. It is antispasmodic; in enemas 30 to

60 grs., with half a pint of gruel, for flatulent colic, &c.

CONFECTION OF SCAMMONY. *Syn.* ELECTUARIUM CARYOCOSTINUM, (P. L. 1720.) DITTO E SCAMMONIO, (P L. 1745.) DITTO SCAMMONII, (P. L. 1809 and 1788.) CONFECTIO SCAMMONEÆ, (P. L. 1809 and 1824.) *Prep.* (*Confectio Scammonii* P. L.) Scammony ℥iss; cloves and ginger, of each, ʒvj; oil of caraway fʒss. Reduce the ingredients to a very fine powder, and when wanted for use, make them into a confection with sirup of roses, and lastly add the oil.

Use, &c. Cathartic in doses of 10 to 30 grs.

CONFECTION OF SENNA. *Syn.* LENITIVE ELECTUARY. ELECTUARIUM SENNÆ, (P. L. 1788.) CONFECTIO SENNA, (P. L. 1809, and since.) *Prep.* (P. L.) Senna ℥viij; figs lb. j; pulp of tamarinds, prunes, and cassia, of each, lb. ss.; coriander seeds ℥iv; liquorice ℥iij; sugar lb. iiss; water 3 pints. *Proc.* Rub the senna and corianders in a mortar, and separate by sifting ℥x of the mixed powders. Boil the figs and liquorice in the water, until reduced to one half; then press and strain the liquor. Evaporate the strained liquor until only 24 fluid ounces remain, then add the sugar, and when dissolved, mix in the pulps, and lastly the powder.

Use, Dose, &c. Confection of senna is a gentle and pleasant purgative, and well adapted for persons suffering from piles, and as a laxative during pregnancy. The dose is ¼ to ½ oz. taken at bedtime or early in the morning.

Remarks. Perhaps there is no one pharmacopœial preparation which it is more difficult to obtain of good quality than the above. The absolute cost of an article prepared according to the directions of the College, will be somewhere about 1*s.* 9*d.* per lb.; but there are many wholesale drug houses vending confection of senna, which they warrant as genuine, at from 9*d.* to 1*s.* a pound. Dr. Paris (in his Pharmacologia) very truly remarks, that "the directions of the Pharmacopœia are very rarely followed." I understand that considerable quantities are manufactured, into which unsound and spoiled apples enter as a principal ingredient. The following forms are, to my knowledge, employed by some members of the trade.

II. Powdered senna, pulp of tamarinds, cassia, and prunes, of each, 1½ lb.; powdered corianders ¾ lb.; Spanish juice ½ lb.; simple sirup 12 lbs.

III. As the above, omitting the cassia pulp, and adding 2 lbs. more tamarind pulp.

Both these articles are labelled P. L., and sent out as genuine, and that when no competition as to price exists. The cheaper article is made as follows:

IV. Common prunes and tamarinds, of each, 16 lbs.; treacle ¾ cwt.; species (a compound of senna dust and small senna, mixed with 3 lbs. of coriander seeds, and strengthened with jalap, all ground to a fine powder) 18¼ lbs. To this is frequently added ¼ cwt. of rotten or inferior apples, which are pulped with the prunes and tamarinds. This article is not unfrequently labelled "CONF. SENNÆ VER." by the conscientious tradesman.

CONFECTION OF SULPHUR, (COMPOUND.) *Prep.* (St. B. H.) Precipitated sulphur ℥ss; cream of tartar ʒj; honey ℥j; mix As a laxative in piles, &c. *Dose.* ℥ss.

CONFECTION OF STEEL. *Syn.* CONFECTION OF CARBONATE OF IRON. *Prep.* Confection of orange-peel and sesquioxide of iron, (P. L.,) of each, 4 oz.; powdered white sugar 6 oz.; simple sirup 2 oz.; mix. Aromatic and tonic. *Dose.* A teaspoonful to ½ oz. twice or thrice daily.

CONGELATION, (from *congelo*, to freeze.) IN CHEMISTRY. The conversion of a liquid into a solid state, by the action of cold.

The production of an extreme degree of cold is often of the utmost importance in chemical operations, and an easy method of doing so is consequently a desideratum. The means hitherto adopted for this purpose have either depended upon the sudden liquefaction of solids, or the abstraction of heat by rapid evaporation. The loss of sensible heat, by the first method, is the basis of the various processes of producing cold by what are commonly called freezing mixtures, all of which act upon the principle of liquefying solid substances without supplying heat. The caloric of liquidity being in these cases derived from that previously existing in the solid itself in a sensible state, the temperature must necessarily fall. The degree of cold produced, depends upon the quantity of heat which is thus diffused through a larger mass, or which, as it were, disappears, and this is dependent on the quantity of solid matter liquefied, and the rapidity of the liquefaction. Saline compounds are the substances most frequently employed, and those which have the greatest affinity for water, and thus liquefy the most rapidly, produce the greatest degree of cold. Thus it is, that chloride of calcium and nitrate of ammonia, when dry and in fine powder, if suddenly mixed with water, produce extreme cold. The latter, suddenly mixed with an equal weight of water at 50°, will sink the thermometer to +4°, or 28° below the freezing point. The most common and convenient freezing mixture, when snow can be procured, is formed by mixing 2 parts of that substance with 1 part of sea-salt. This will sink the thermometer to −5°, or 37° below the freezing point of water. Equal parts of these substances produce a degree of cold marked by the zero of Fahrenheit's thermometer, and is the standard taken for graduating that instrument. Mr. Walker, a gentleman who fully investigated this subject, recommends the following proportions for the production of extreme cold.

TABLES *exhibiting a collective View of all the* Frigorific Mixtures *contained in* Mr. Walker's *Publication,* 1808.

Table I. Consisting of Frigorific Mixtures, composed of Ice, with Chemical Salts and Acids.

Mixtures	Thermometer sinks.	Degree of cold produced.
Snow or pounded ice . . . 2 parts Muriate of soda . . 1 "	From any temperature to —5°	*
Snow or pounded ice . . 5 " Muriate of soda . . 2 " Muriate of ammonia . 1 "	From any temperature to —12°	*
Snow or pounded ice . . 24 " Muriate of soda . . . 10 " Muriate of ammonia . 5 " Nitrate of potash . . . . 5 "	From any temperature to —18°	*
Snow or pounded ice 12 " Muriate of soda . . . 5 " Nitrate of ammonia . . 5 "	From any temperature to —25°	*
Snow . . . . 3 " Diluted sulphuric acid† . . 2 "	From +32° to —23°	55°
Snow . . . . 8 " Muriatic acid (concentrated) . 5 "	From +32° to —27°	59
Snow . . . . 7 " Concentrated nitrous acid . 4 "	From +32° to —30°	62
Snow . . . . 4 " Muriate of lime . . . . 5 "	From +32° to —40°	72
Snow . . . . 2 " Crystallized muriate of lime . 3 "	From +32° to —50°	82
Snow . . . . 3 " Potash . . . . . . 4 "	From +32° to —51°	83

N. B. The reason for the omissions in the last column of this table is, the thermometer sinking in these mixtures to the degree mentioned in the preceding column, and never lower, whatever may be the temperature of the materials at mixing.

Table II. Consisting of Frigorific Mixtures, having the power of generating or creating Cold, without the aid of Ice, sufficient for all useful and philosophical purposes, in any part of the world at any season.

Mixtures.	Thermometer sinks.	Degree of cold produced.
Muriate of ammonia . . . 5 parts Nitrate of potash . . . . 5 " Water . . . . . 16 "	From +50° to +10°	40°
Muriate of ammonia . . 5 " Nitrate of potash . . . . 5 " Sulphate of soda . 8 " Water . . 16 "	From +50° to +4°	46
Nitrate of ammonia . . 1 " Water . . . . . . 1 "	From +50° to +4°	46
Nitrate of ammonia . . . 1 " Carbonate of soda . . 1 " Water . . . . 1 "	From +50° to —7°	57
Sulphate of soda . . 3 " Diluted nitrous acid‡ . 2 "	From +50° to —3°	53
Sulphate of soda . . . 6 " Muriate of ammonia 4 " Nitrate of potash . . . 2 " Diluted nitrous acid . . . 4 "	From +50° to —10°	[illegible]

† Strong acid 2 parts; water or snow 1 part, by weight.
‡ Fuming nitrous acid 2 parts; water 1 part, by weight.

Table II. continued.

Mixtures.		Thermometer sinks.	Degree of cold produced.
Sulphate of soda . . . . . Nitrate of ammonia . . . . Diluted nitrous acid	6 parts 5 " 4 "	From +50° to —14°	64°
Phosphate of soda . . . . Diluted nitrous acid	9 " 4 "	From +50° to —12°	62
Phosphate of soda . . . . Nitrate of ammonia . . . . Diluted nitrous acid	9 " 6 " 4 "	From +50° to —21°	71
Sulphate of soda . . . . . Muriatic acid	8 " 5 "	From +50° to 0°	50
Sulphate of soda . . . . . Diluted sulphuric acid* . . .	5 " 4 "	From +50° to +3°	47

N. B. If the materials are mixed at a warmer temperature than that expressed in the Table, the effect will be proportionately greater; thus, if the most powerful of these mixtures be made when the air is +85°, it will sink the thermometer to +2°.

TABLE III. Consisting of Frigorific Mixtures selected from the foregoing Tables, and combined so as to increase or extend Cold to the extremest Degrees.

Mixtures.		Thermometer sinks.	Degree of cold produced.
Phosphate of soda . . . . Nitrate of ammonia . . . . Diluted nitrous acid	5 parts 3 " 4 "	From 0° to —34°	34°
Phosphate of soda . . . . Nitrate of ammonia . . . . Diluted mixed acids	3 " 2 " 4 "	From —34° to —50°	16
Snow . . . . Diluted nitrous acid	3 " 2 "	From 0° to —46°	46
Snow . . . . Diluted sulphuric acid . . . Diluted nitrous acid	8 " 3 " 3 "	From —10° to —56°	46
Snow . . . . Diluted sulphuric acid	1 " 1 "	From —20° to —60°	40
Snow . . . . Muriate of lime	3 " 4 "	From +20° to —48°	68
Snow . . . . Muriate of lime . .	3 " 4 "	From +10° to —54°	64
Snow . . . . Muriate of lime . . .	2 " 3 "	From —15° to —68°	53
Snow . . . . Crystallized muriate of lime . .	1 " 2 "	From 0° to —66°	66
Snow . . . . Crystallized muriate of lime . .	1 " 3 "	From —40° to —73°	33
Snow . . . . Diluted sulphuric acid . . .	8 " 10 "	From —68° to —91°	23

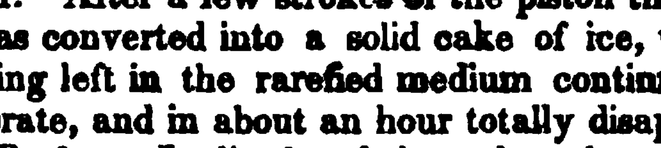
Remarks. The above artificial processes for the production of cold are more effective when the ingredients are first cooled by immersion in other freezing mixtures. In this way Mr. Walker succeeded in producing a cold equal to 100° below the zero of Fahrenheit, or 132° below the freezing point of water.

The materials in the first column are to be cooled, previously to mixing, to the temperature required, by mixtures taken from either of the preceding tables.

* Equal weights of strong acid and water.

II. (*By evaporation.*) When heat passes from the sensible to the insensible state, as in the formation of vapor, cold is generated. This may be illustrated by pouring a few drops of ether, or highly rectified alcohol, on the palm of the hand, when a strong sensation of cold will be produced. In like manner, if the bulb of a thermometer be covered with lint, and the latter moistened with ether, the quicksilver will rapidly fall. Even in hot climates water is frozen by the joint operation of evaporation and radiation. The natives of India procure ice when the temperature of the air much exceeds the freezing point. On the open plains, near Calcutta, this is effected by exposing a thin stratum of water to the atmosphere, during the fine clear nights of December, January, and February. The pans are made of porous earthenware, and water is poured in to the depth of about $1\frac{1}{2}$ inches. A large number of vessels of this kind are arranged in an excavation in the ground, 30 or 40 feet square and 2 feet deep, the bottom of which is covered, to the depth of 10 or 12 inches, with sugar canes or the stalks of Indian corn. At sunrise the pans are visited, the ice separated from the water, and packed as tight as possible in a deep cavity or pit, well screened from the heat.

It has been found that evaporation proceeds much more rapidly from the surface of fluids in a vacuum than in the atmosphere. Dr. Cullen was the first person to apply this practically. In 1755 he plunged a vial of ether into a tumbler of water, and on placing it under a receiver and exhausting the air, the ether boiled and the water was speedily frozen. In 1777, Mr. Nairne published his method of rendering the rarefied atmosphere of an exhausted receiver free from aqueous vapor by means of sulphuric acid. By the application of this discovery, Professor Leslie in 1810 succeeded in freezing water with great ease. This he effected by introducing a surface of sulphuric acid under the receiver of an air-pump, over which he placed a watch-glass filled with water, so that the vapor arising from the latter was rapidly absorbed by the former. After a few strokes of the piston the water was converted into a solid cake of ice, which on being left in the rarefied medium continued to evaporate, and in about an hour totally disappeared. Professor Leslie found that when the air was rarefied 250 times, the surface of evaporation was cooled down 120° in winter, and when only 50 times, a depression of 80° or even 100° took place. A pleasing philosophical toy, illustrative of the evaporative power of a vacuum, is the Cryophorus, or frost-bearer of Dr. Wollaston. This instrument consists of two small glass globes united by a tube, one of which is partly filled with water, but the apparatus is perfectly free from air.



The part of the apparatus unoccupied by the water, though apparently empty, is in reality filled with aqueous vapor, and thus checks evaporation by its pressure on the surface of the water. No sooner is the pressure removed, as by plunging the empty ball into a freezing mixture, (which condenses the vapor,) than rapid evaporation commences, and the water in the other ball is frozen in two or three minutes.

To succeed well in the production of cold in this way, it is necessary that the surfaces of the two fluids should be pretty near together, and that the acid should have the greater amount of surface of the two. The acid should be poured to the depth of $\frac{1}{2}$ an inch into a broad shallow dish or capsule, and the water into another vessel of a similar kind, but having only half the diameter of the former, and proportionally shallow. The smaller capsule may be supported over the surface of the larger one by means of 3 slender feet. As soon as the acid has acquired one-tenth of its weight of water, its absorbent power is diminished $\frac{1}{100}$; when this dilution reaches $\frac{1}{4}$ the reduction is $\frac{1}{25}$, and when it reaches $\frac{1}{2}$ the cooling power has diminished about 50%. "Sulphuric acid is capable of congealing more than 20 times its weight of water before it has imbibed nearly its own bulk of that liquid, or has lost about $\frac{1}{8}$ of its refrigerating power." (Ure.) Sulphuric acid, which has become diluted in this way, may be reconcentrated by heat.

It has been discovered that oatmeal, dried nearly to brownness before a common fire, and cooled in close vessels, may be substituted for sulphuric acid. With a quantity of this substance, one foot diameter, and 1 inch deep, Professor Leslie froze 1 imperial pint of water, contained in a hemispherical porous cup. Ignited chloride of calcium, in porous pieces, has also been successfully used for the same purpose. Dr. Ure has found that a requisite vacuum may be produced by the agency of steam, in the following manner, without the use of an air-pump: "A cast-iron drum of considerable dimensions being filled with steam by heating a small quantity of water in it, will sufficiently expel the air. When it is cooled by the affusion of water, a transferrer plate being attached to the stopcock on its upper surface would easily enable us, without any air-pump, to effect congelation by means of sulphuric acid in the attenuated atmosphere. Suppose the capacity of the receiver to be one-sixtieth of the iron cylinder, an aëriform rarefaction to this degree would be effected in a moment by a turn of the stopcock; and, on its being returned, the moisture below would be cut off, and the acid would speedily condense the small quantity of vapor which had ascended."

Many curious experiments may be performed over sulphuric acid, in the receiver of an air-pump, among which one of the most instructive and amusing is the congelation of quicksilver, a metal which requires, for this purpose, a temperature of 39° below zero, or 71° below the freezing point of water. This is readily effected by suspending the metal in a capsule of ice by means of threads, near to the surface of the sulphuric acid, and urging the rarefaction as much as possible. Mercury so frozen may be kept in the solid state for several hours.

The processes of congelation above detailed admit of being applied to several useful purposes, especially in domestic economy, and the arts of the cook and confectioner, as in the making of ices, &c.

CONGREVE MATCHES. I. (*Process of M. Jeblonouski.*) Put phosphorus 40 grammes into a wide-mouthed vial, with enough oil of turpentine to cover it, add flowers of sulphur 10 gr.,

and put the vial into hot water, (using great caution,) until the phosphorus is melted. Then cork close and agitate until cold, when any supernatant spirits of turpentine must be poured off. Into this pulpy mass the extremities of the matches are dipped, and when they have become *rather* dry, they are again dipped into the following mixture: Gum arabic 30 grammes, (dissolved in a little water;) chlorate of potassa 20 grammes; soot, or vermilion, (rubbed up with a few drops of alcohol,) 10 gr.; mix, and dip the tips of the matches therein as before, then dry them cautiously in a warm apartment. These matches inflame without fulmination (noise) on being rubbed against any rough surface.

II. (*Joblonouski.*) Chlorate of potassa 2 parts; phosphorus 4 parts; gum arabic 7 parts; gelatin 2 parts. *Proc.* The phosphorus is divided in the gum brought to the state of thick mucilage, and warmed; the gelatin is melted and added to the phosphoreted mucilage. The chlorate of potassa is bruised in a mortar, and at the same time moistened with the mucilage. When it is bruised the whole is mixed together, and a paste is obtained, with which matches, tipped with sulphur, may be embued. They are then dried in the air.

III. (*Process of Dr. R. Boettger.*) Gum arabic and vermilion, of each 16 parts; phosphorus 9 parts; saltpetre 14 parts. *Proc.* The phosphorus must be reduced to a state of fine division, by agitating it with fresh urine, or, still better, a solution of pure urea, which, in consequence of the discovery by Liebig, of a process of preparing that substance artificially, may now be easily procured or made. Hot water must be employed to melt the phosphorus, and this part of the process is similar to that previously detailed. The minutely divided phosphorus thus formed, is mixed with the other articles made into a paste, with the gum dissolved in the least quantity of water, and the matches dipped into the mingled ingredients and dried. They are then dipped into a dilute varnish of copal, or a thin solution of gum arabic containing saltpetre, and again dried. (Boettger's Beitrage.) These matches are very superior, and explode without noise.

Remarks. The matches formerly made, exploded with a crackling noise, and frequently threw out small sparks of fire, which rendered them dangerous. This arose from their containing too large a quantity of chlorate of potassa. An opposite plan is now generally followed, and a less proportion of the chlorate is used, or instead thereof saltpetre. The quantity of the igniting ingredients has also been greatly lessened, so as to avoid any danger on that account. This plan answers very well, when the body of the matches, whether of wood or pasteboard, is properly prepared; but if this be not the case, frequent disappointment will occur, from their going out again immediately after inflaming. To prevent this, the matches should be dipped into sulphur previously to coating them with the composition, unless intended for cigar fusees, when they should be prepared by soaking them in water holding some saltpetre, bichromate of potash, or acetate of lead in solution, preference being usually given to the first of these articles. Different coloring substances are employed to tint the composition, according to the fancy of the manufacturer, as smalts, red lead, vermilion, black oxide of manganese, soot, &c. A very elegant method of reducing phosphorus to a state of minute division, is to melt it in rectified spirit, and agitate until cold, as above.

The manufacture and sale of matches, containing sulphur and phosphorus, as in the first formula, have been forbidden in Paris, in consequence of the extreme facility with which they ignite, having led to several accidents. (See CHLORATE MATCHES, and LUCIFERS.)

CONIA. *Syn.* CONEINE. CONICIN. CICUTINE, &c. A poisonous alkaloid, discovered by Giesecke in hemlock.

Prep. Distil the seeds of hemlock, or their alcoholic extract, with water and potassa. During this process, the conia passes over into the receiver and floats upon the top of the water, which also contains a little conia in solution. It must be purified in the way directed for the volatile bases. (See ALKALOID.) If the alcoholic extract be employed, about ½ its weight of potassa should be used.

Remarks. 6 lbs. of fresh and 9 lbs. of dried seeds yielded 1 oz. of conia. (Gieger.) 40 lbs. of the ripe but green seeds yielded 2½ oz. of hydrated conia. (Christison.) It is remarkably poisonous. One drop, placed in the eye of a rabbit, killed it in 9 minutes. Five drops, poured into the throat of a dog, killed it in less than a minute. It has been employed in some convulsive and spasmodic diseases. "The plaintive cries, the contortions, and the rigidity of the limbs, which have always preceded death, (caused by conia,) leave no doubt as to the cruel pains which this kind of poisoning brings on." (Boutron-Chalard and Henry.)

CONSERVES. (From *conservo*, to keep.) In pharmacy, a composition of some recent vegetable matter and sugar, beat together to the consistence of a paste. The object aimed at in the preparation of conserves, is to preserve the properties of the active ingredient, which would otherwise be liable to change. In the last edition of the London Pharmacopœia, conserves, as well as electuaries, are included under the head of confections. The term confection appears, however, less appropriate to some of them, than the word conserve or electuary. The word confection has a more general application, and implies any sweetmeat or composition, in which sugar is the principal ingredient.

CONSERVE OF ALMONDS. (CONSERVA AMYGDALARUM, P. D.) Confection of almonds.

CONSERVE, ANTISCORBUTIC. (CONSERVA ANTISCORBUTICA. Selle.) Horseradish, water-cress, water-trefoil, radish juice, and orange juice, of each equal parts; white sugar enough to make a confection.

CONSERVE OF ARUM. (WAKEROBIN.) *Prep.* Fresh arum roots ½ lb.; white sugar 1½ lb.; beat together. Diuretic and attenuant.

CONSERVE OF LAVENDER. *Prep.* Lavender flowers 1 part; lump sugar 3 parts; beat together.

Remarks. In a similar way conserves are made from various other leaves and flowers; but mostly with only twice their weight of sugar. The above is frequently used to sweeten the breath.

CONSERVE OF LEMON-PEEL. *Prep* Rasp off the external rind of the lemon, and beat

it in a mortar with three times its weight of powdered white sugar. (See CONFECTION OF ORANGE-PEEL.) Tonic and stomachic.

CONSERVE OF ORANGE-PEEL. (CONSERVA AURANTII, P. E.) The same as the confection of orange-peel, P. L.

CONSERVE OF RED ROSES. (CONSERVA ROSÆ, P. E. and D.) That of the Dublin Pharmacopœia is the same as the confection of roses, P. L.; that of the Edinburgh has only 2 lbs. of sugar to 1 lb. of rose petals.

CONSERVE OF ROSEMARY. *Prep.* 1 part of the leaves or tops, beaten up with 3 parts of sugar.

CONSERVE OF SCURVY GRASS. *Syn.* CONSERVA COCHLEARIÆ HORTENSIS. *Prep.* Beat 1 lb. of the leaves with 3 lbs. of lump sugar. Stimulant and antiscorbutic.

CONSERVE OF SLOES. *Syn.* CONSERVA PRUNI SYLVESTRIS, (P. L. 1788.) Pulp of sloes 1 part; sugar 3 parts; mix.

CONSERVE OF SQUILLS. *Syn.* CONSERVA SCILLÆ, (P. L. 1788.) Fresh squills ℥j; white sugar ℥v; mix. Diuretic; attenuant.

CONSERVE OF TAMARINDS. *Syn.* CONSERVA TAMARINDORUM. *Prep.* (P. Cod.) Pulp of tamarinds 4 oz.; white sugar 6 oz.; heat by a water-bath in an earthen vessel, until mixed and of a due consistence.

CONSERVE OF WORMWOOD. *Syn.* CONSERVA ABSINTHII MARITIMI, (P. L. 1788.) *Prep.* Beat fresh-picked leaves of sea wormwood in a marble mortar, with a wooden pestle, first alone, and then with 3 times their weight of refined sugar.

CONSTIPATION, (OF THE BOWELS.) Costiveness. When this is merely accidental or occasional, a dose of some cathartic is the only treatment necessary, but when it is *habitual*, it calls for further attention. The common causes of constipation are—The use of bread containing alum, and water containing lime; and the want of sufficient exercise. The treatment should consist in adopting a diet free from astringents, and consisting of a large portion of green vegetables and ripe fruit. Brown bread is frequently eaten for this purpose, and acts by the laxative nature of the bran it contains. The *occasional* use of laxative and emollient enemata may be had recourse to, but their habitual administration, as well as that of purgative medicines, by the mouth, is not to be recommended. The bowels, accustomed to the continual use of stimulants, act but languidly, or scarcely at all, without their application. In females, especially of the higher classes, the want of proper exercise is generally the chief cause of constipation. With such persons, a short walk two or three times daily will often do wonders, particularly if a little ripe fruit, a few raisins or tamarinds, or 2 or 3 drum figs, be occasionally eaten.

COPAIBA. *Syn.* CAPIVI. BALSAM OF CAPIVI. The best copaiba is that imported from Maracaibo and St. Martha, and is packed in casks containing from 1 to 1½ cwt. each, in large bottles, or in cylindrical tin boxes. Considerable variation exists in the color, consistence, and sp. gr., as well as in the proportion of oil and resin yielded by different samples, scarcely any two of which exactly agree. Even the odor, taste, and transparency vary considerably. Brazilian capivi is thin, clear, and pale; while the West Indian is thick, golden yellow, less transparent, and has a less agreeable and somewhat terebinthinate smell. Some varieties are opaque, and continue so, unless filtered. This is a most troublesome operation, unless well managed, and without proper precautions, frequently proves useless. The opacity generally arises from the presence of water, which is frequently found mixed with copaiba when first imported. This it retains with great tenacity. The following is the plan I have found to answer on the large scale. Place the casks upon their ends in a warm situation, and leave them so for a fortnight, or longer, if convenient. They may then be tapped *a little above the bottom*, when some of them will generally be found quite transparent, and may be drawn off and vatted, care being taken to avoid shaking up the bottom. Those that are foul must be filtered through one or more long Canton flannel bags, sunk in the bottom of a tin cistern, placed over a suitable receiver; a few pounds of coarsely-powdered charcoal being mixed up with the first 5 or 6 gallons thrown in. This will rapidly fill up the pores of the bag, and make the balsam flow clear and pale. The first runnings should be returned until it becomes perfectly transparent. The bottoms of the casks, containing the water or impurities, may be poured into a large can or jar, and allowed to deposite for a few days, when the copaiba may be poured off the top, and filtered. A sudden change of temperature will frequently turn a brilliant sample of this article opaque or milky; it is not, therefore, deemed fit to send out by the wholesale trade, unless it will "*stand*" this test. To ascertain this point, a common practice is to fill a small bottle with the copaiba, and to leave it out of doors all night in an exposed situation. (See also BALSAM OF COPAIBA.)

COPAIBA, ALKALINE TINCTURE OF. (LEWIS THOMPSON.) *Prep.* Dissolve 2 oz. of carbonate (formerly subcarbonate) of potassa in 1 pint of water, and add to this, balsam of copaiba in a thin stream, constantly stirring the mixture, until this, at first white and milky, becomes clear like jelly or amber, which will generally take place when about a pint of balsam has been added; set the mixture aside for two or three hours, then pour in two pints of spirit of wine, and mix the whole together; the solution is then fit for use, and may be flavored with any of the essential oils. Sweet spirit of nitre may be substituted for spirit of wine; but it is necessary to destroy its acidity by distillation from lime or potassa, otherwise a decomposition will take place.

This solution is compatible with iodide of potassium and nitrate of potassa, but is decomposed by all earthy, metallic, and ammoniacal salts, such as sulphate of magnesia, chloride of iron, acetate of ammonia, &c., which must not, therefore, be administered in conjunction with it. (Chemist, iv 510.)

COPAIBA AND KALI. *Prep.* Carbonate of potassa and water, of each equal parts; dissolve, and add gradually transparent balsam of copaiba until the fluid, at first milky, turns quite clear

COPAIBA CAPSULES. Gelatinous capsules filled with balsam of copaiba.

COPAIBA AND RHATANY, CAPSULES OF. Ricord has recommended capsules of copaiba, coated with extract of rhatany, as much superior to the common ones of copaiba alone, in the treatment of blenorrhœa. They may be easily prepared by either of the two following methods:

1. By immersing, for an instant, the common capsule in the following composition: or,
2. By forming the bodies of the capsules with the *composition*, instead of with *gelatin*, and following the same manipulations as for the manufacture of the common gelatin capsules.

The Rhatany Composition. Extract of rhatany, newly prepared from the root, 3 parts; sirup of moist sugar 1 part; mucilage of gum arabic 1 part. Melt the extract and reduce it in a water bath until sufficiently stiff, when cold; do the same with the sirup and gum; then mix them together while hot, but only in such quantity as may be used at one time.

These capsules are said to sit well upon the stomach, the tone of which they contribute to improve.

COPAIBA, MISCIBLE. *Prep.* Mix transparent balsam of copaiba with half its volume of liquor of potassa of double strength.

Remarks. Different samples of balsam often require *slightly* different quantities of the solution of potassa; it is therefore best to mix them gradually and cautiously together. Should the mixture be opaque, a *little* more, of one or other of the ingredients, as the case may be, will render it clear. No heat should be used. This article is miscible with water, with which it forms a kind of milk; and from containing *all* the volatile oil of the copaiba is a very valuable preparation. Its activity is considered equal to the balsam itself, and it is given in similar doses.

COPAIBA, MIXTURE OF. (CHOPART.) *Prep.* Copaiba, alcohol, sirup of Tolu, peppermint water, orange-flower water, of each ℥ij; sweet spirits of nitre ʒij. *Proc.* Rub the copaiba with the sirup until perfectly mixed, then add the spirits, and lastly the waters.

COPAIBA, SOLUBLE. *Prep.* I. Heat miscible copaiba to the boiling point, pour it while hot into a "*separator*," and place it in some situation where it will cool slowly. After a few days draw off the clear portion from a cock or hole placed *near* the bottom of the vessel, observing to stop the stream before any of the floating oil begins to flow through. *A very little* concentrated liquor of potassa added before applying the heat, will render it more soluble. *Prod.* Thick, clear, and soluble in pure water. Resembles copaiba in appearance.

II. Agitate balsam of copaiba with an equal measure of liquor of potassa, (P. L.;) boil for a few minutes in a clean tinned copper pan, then pour it into a separator, and proceed as before. Thinner than the last.

COPAIBA, SPECIFIC SOLUTION OF. (FRANK'S.) *Prep.* I. Balsam of copaiba 2 parts; liquor of potassa (P. L.) 3 parts; water 7 parts; boil it for 2 or 3 minutes, put it into a separator, and allow it to stand for 5 or 6 days, then draw it off from the bottom, avoiding the upper stratum of oil. To the clear liquid add 1 part of sweet spirits of nitre, perfectly free from acid, to which a few drops of liquor of potassa has been added, until it slightly browns turmeric paper; should it turn foul or milky, a *very little* liquor of potassa will usually brighten it; if not, place it in a clean separator for a few days, and draw it off from the bottom as before, when it will be perfectly brilliant without filtering.

Remarks. Some persons add the sweet spirits of nitre while the solution is still hot, mix it in as rapidly as possible, and immediately cork or fasten up the vessel. This is a good way when the article is wanted in a hurry, but is objectionable from the loss of spirit thereby occasioned, and the danger, without care, of bursting the separator.

A receipt for this article, upon the authority of Battley, has been going the round of the pharmaceutical works for some years, but which produces a preparation not at all resembling "*Frank's specific solution.*" It is as follows: "Take 12 oz. of balsam of copaiba and 6 oz. of calcined magnesia; rub together, add a pint of proof spirit, filter, and then add ½ oz. of sweet spirits of nitre." (Gray's Supplement.) I have tried this formula, and I find the product to be a white tincture, scarcely flavored with copaiba, and perfectly limpid. No sooner is balsam of copaiba mixed with half its weight of magnesia, than the two unite, and produce a compound insoluble in spirit of wine. Such is the affinity of this earth for copaiba, (copaibic acid,) that it will even take it from caustic potassa. Thus I find the solution of this balsam, (containing potassa,) if filtered through blotting-paper, with a little magnesia, becomes so strongly alkaline as to materially injure its quality, while a glutinous mass is deposited upon the sides and bottom of the paper. I have been led to a notice of this subject, from well knowing that many druggists have adopted this formula, and have been disappointed with the results, which are, however, only such as might be reasonably anticipated.

COPAIBA, SALT OF. *Syn.* SAL COPAIBÆ. There are two preparations bearing this name, the one, copaibic acid, and the other, copaibate of an alkali. They are both sold at ridiculously high prices. The advertisement of one of these preparations is heralded in with the following pseudo-philosophical announcement:

"*This preparation* of copaiba, in its chemical and medical analogies, may be compared to quinine from bark, the former being the tonic of the mucous membranes, and the latter that of the dermoid structures.

"*This salt* contains all the properties of the balsam of copaiba in a very concentrated form, without its nauseating qualities, and from this circumstance it may be administered to the most delicate constitution."

It is the general opinion of medical men, that the active properties of copaiba reside in a volatile or essential oil, of which the *above preparation is destitute.* It is therefore difficult to conceive how, in *this* instance, the reverse should be the case. I can speak from my own experience, and that of several high authorities to whom I have referred, that both the viscid and acid resins of copaiba are almost inert, and that all the alkaline preparations of these substances are nearly similar. I have taken the "sal copaibæ" myself, and have watched its action on others, but have not been able to

perceive any good effects to result from its administration.

COPAIBIC ACID. *Syn.* CAPIVIC ACID. The yellow brittle resin of balsam of copaiba. It is prepared by digesting the resin (left after distilling the oil from the balsam) in alcohol, which dissolves the acid resin, but leaves the viscid one. It may be purified by re-solution in alcohol. It forms about 50% of the balsam.

Prop. An amber-colored, brittle, semi-crystalline, resinous substance, soluble in alcohol, ether, and oils, reddens litmus paper, and forms salts with the bases, called copaivates. These may generally be made by dropping into a solution of the acid in alcohol, an alcoholic solution of a soluble salt of the base. The copaivates of potash, soda, and ammonia are easily prepared, by adding to an alcoholic solution of the acid another of the pure alkali, until it be neutralized, when the salts may be obtained by careful evaporation. Copaivate of silver is formed by neutralizing the acid with nitrate of silver, both being dissolved in alcohol, and then adding a little liquor of ammonia, when a white crystalline precipitate will subside. The copaivates of lead, lime, and iron, as well as several others, may be made in a similar manner.

Copaivate of magnesia may be made by adding copaivate of potassa to a solution of epsom salts. All these salts are easily decomposed by acids.

COPAL. *Syn.* GUM COPAL. A resinous substance, which exudes spontaneously from the Rhus copallinum, and the Elæocarpus copalifer. When of good quality, it is too hard to be scratched by the nail, and has a conchoidal fracture. It dissolves with difficulty, and this, combined with its extreme hardness, renders it very valuable for making varnishes.

SOLVENTS. I. *Caoutchoucine;* sparingly. II. Equal parts of *caoutchoucine* and *alcohol*, of ·825; freely soluble in the cold. III. *Absolute alcohol*, added gradually to the copal, previously rendered gelatinous by water of ammonia, assisting the union with heat. IV. *Alcohol* added to the copal, previously softened with ether. V. *Absolute alcohol* 1½ parts, digested on copal 1 part for 24 hours. (Unverdorben.) VI. *Alcohol*, to which a little camphor has been added. VII. *Ether;* and this solution may be diluted with alcohol. VIII. *Oils of rosemary* and *lavender*, (spike;) too expensive for general use. IX. *Copal*, heated until it fuses, acquires the property of dissolving in turpentine and alcohol. X. *Copal*, reduced to powder and exposed for some time to the air, also becomes soluble in alcohol and turpentine. XI. *Drying linseed oil*, at nearly the boiling point, dissolves copal, and will bear dilution with spirits of turpentine as soon as it has cooled sufficiently. This is the common way of making copal varnish. XII. *Ammonia* enables oil of turpentine to dissolve copal; but it requires such nice management of the fire, that it seldom succeeds completely. (Lewis.) XIII. *Powdered copal*, triturated with a little camphor, softens and becomes a coherent mass; and camphor, added either to alcohol or oil of turpentine, renders it a solvent of copal. ½ oz. of camphor is sufficient for 1 quart of oil of turpentine, which should be of the best quality; and the copal, about the size of a large walnut, should be broken into very small pieces, but not reduced to a fine powder. The mixture should be set on a fire so brisk as to make it boil almost immediately The vessel should be of tin or other metal, strong, shaped like a wine-bottle with a long neck, and capable of holding 2 quarts. The mouth should be stopped with a cork, in which a notch is cut to prevent the vessel from bursting. (Sheldrake.) XIV. A good varnish may be made by pouring upon the purest lumps of copal, reduced to a fine mass in a mortar, colorless spirits of turpentine, to about one third higher than the copal, and triturating the mixture occasionally in the course of the day. Next morning it may be poured off into a bottle for use. Successive portions of oil of turpentine may thus be worked with the same copal mass. (Varley, Tilloch's Mag. 51.)

*** In all the above cases the copal should be reduced to a *coarse* powder. A *fine* powder is apt to stick together and form hard lumps. The solution of copal, even in its most ready solvents, is attended with some difficulty, and frequently miscarries in the hands of the inexperienced. A mixture of caoutchoucine and alcohol (as in No. II.) is an exception.

COPAL, MELTED. Obtained by holding the gum before a good fire, so that as soon as the copal melts, it may drop into a pan of water: a kind of oil separates from it, and the copal becomes soluble in spirits of wine, and still more so if the melting is repeated.

COPAL, POWDERED. Copal reduced to powder and exposed to the air in a thin stratum, on sieves covered with paper, for 3 or 4 months. Soluble in alcohol.

COPPER. (From *cuprum*, a corruption of *κύπρος*, from the island of Cyprus, whence it was formerly brought.) A red-colored metal, too well known to require description.

Hist. Copper and its alloys appear to have been known to the most remote ages of antiquity. Brass, an alloy of copper, is mentioned by Moses (Job, xxviii.) upwards of 1600 years before the birth of Christ. (Hales.) This metal is found in the metallic state, and in combination with oxygen, sulphur, acids, and other minerals, and in the organic kingdom, in the ashes of plants, and in the blood of animals. (Sarzeau.) The copper of commerce is principally prepared from copper pyrites, a mixed sulphuret of iron and copper, found in Cornwall, and other parts of the world.

Prep. Copper is only prepared from its ores on the large scale. The copper pyrites is first roasted, and then smelted, by which process "*coarse metal*" is produced; this is again submitted to calcination and smelting, when "*fine metal*" is obtained. It afterwards undergoes the process of refining and toughening.

Prop. This metal is malleable and ductile. It has a specific gravity of 8·8 to 8·9, fuses at about 2000° Fahr., and volatilizes at higher temperatures. It forms numerous compounds, all of which are more or less poisonous.

Char. and Tests. The solutions of copper possess a blue or green color, and yield a blue precipitate with soda or potassa. Ammonia produces a bluish-white precipitato, soluble in an excess of the precipitant, forming a deep blue solution. Prussiate of potash gives a reddish-brown precipitate, sulphureted hydrogen and hydrosulphurets, a black

ac. A polished iron plate, immersed in an acidulous solution of copper, becomes coated with that metal.

Estim. The quantity of copper present in any compound, may be estimated by throwing it down from its solution by pure potassa, after which it must be carefully collected, washed, dried, ignited, and weighed. This will give the quantity of the oxide from which its equivalent of metallic copper may be calculated; every 5 parts of the former being (as near as possible) equal to 4 of the latter. Copper may also be precipitated at once in the metallic state, by immersing a piece of polished steel into the solution, but this method will not give very accurate results. Copper may be separated from lead by adding sulphuric acid to the nitric solution, and evaporating to dryness, when water digested on the residuum will dissolve out the sulphate of copper, but leave the sulphate of lead behind. From this solution the oxide of copper may be thrown down as before. Copper may be separated from zinc by sulphureted hydrogen, which will throw down a sulphuret of copper, which may be dissolved in nitric acid, and treated as above.

Uses. The applications of copper in the arts are too well known to require notice. In medicine, 3 or 4 grains of the filings were formerly given in rheumatism, and to prevent hydrophobia.

Ant. Copper in the metallic state appears to be inert, but most of its compounds are poisonous. The antidotes are, the white of egg, milk, or flour mixed with water. Iron filings (Payen, Chevallier, Dumas) and the prussiate of potash have also been recommended. A drachm or more of the latter may be taken dissolved in water, and ½ oz. or more of the former, ad libitum. Sugar has also been proposed as an antidote. (Duval, Postel.)

COPPER, ALLOYS OF. With *zinc* copper forms *brass;* with *tin, bronze, bell,* and *cannon metal.* An alloy made with 100 parts of copper and 50 of tin, forms *speculum metal. White copper* is formed by the addition of metallic arsenic, and *German silver* is a mixture of nickel, zinc, and copper. See these articles in their alphabetical places.

COPPER, ACETATES OF. I. (*Neutral Acetate. Syn. Distilled Verdigris. Binacetate of Copper. Crystallized Verdigris.*) *Prep.* Dissolve verdigris in vinegar, with the aid of heat, and crystallize. It forms dark green or blue crystals.

II. (*Diacetate. Syn. Verdigris. Ærugo.*) Formed by exposing sheets of copper to the vapor of acetic acid, in a warm situation. (See VERDIGRIS.) It forms a green or bluish-green powder.

III. (*Sesquibasic Acetate.*) The blue portion of verdigris, soluble in water.

IV. (*Trisacetate.*) The green insoluble portion of verdigris.

COPPER, ARSENITE OF. *Syn.* SCHEELE'S GREEN. *Prep.* Mix a solution of 2 parts of sulphate of copper in 44 of water, with a solution of 2 parts of potash of commerce, and 1 of pulverized arsenious acid, also in 44 of water. Both solutions being warm, the first is to be gradually poured into the second. The grass-green insoluble precipitate is to be washed with water.

COPPER, AMMONIURETED. *Syn.* CUPRO-SULPHATE OF AMMONIA. AMMONIATED COPPER, (P. E.) *Prep.* (*Ammonio-sulphate of Copper,* P. L.) Sulphate of copper ℥j; sesquicarbonate of ammonia ℥iss. Rub them together until carbonic acid ceases to evolve, then wrap it up in bibulous paper and dry it in the air.

Prop. By heat ammonia is evolved, and oxide of copper remains. Its aqueous solution changes the color of turmeric, and a solution of arsenious acid renders it green. (P. L.)

Uses. Employed in pyrotechny. It has been given in doses of ½ to 5 grs. in chorea, epilepsy, hysteria, &c., but it is principally employed as an injection and as a collyrium, in opacity of the cornea.

Remarks. Great care must be taken in drying this article, as it is apt not only to lose a large portion of its weight, but become of an inferior color. Both the ingredients should be separately reduced to powder before mixing.

COPPER, BEAN-SHOT. *Prep.* Melt copper, and pour it in a small stream into boiling water. It is in small lumps like peas or beans, hence its name.

COPPER, BLANCHED. *Prep.* Fuse copper with $\frac{1}{18}$ of its weight of neutral arsenical salt, under a flux of calcined borax, charcoal, and powdered glass.

COPPER, CARBONATE OF. *Syn.* DICARBONATE OF COPPER. MINERAL GREEN. *Prep.* Add a solution of carbonate of soda or potassa to a hot solution of protosulphate of copper.

Remarks. The beautiful green mineral called *malachite,* is a hydrated dicarbonate of copper. If the solution of copper in the above formula be employed cold, the precipitate has a bluish-green color. (See VERDITER.)

COPPER, CHLORIDES OF. *Prep.* I. (*Subchloride. Syn. Dichloride of Copper. Resin of ditto. White muriate of ditto.*) Distil a mixture of 1 part of copper filings, with two parts of corrosive sublimate.

II. (*Chloride. Syn. Muriate of Copper. Hydrochlorate of ditto. Protochloride of ditto.*) Dissolve protoxide of copper in muriatic acid, evaporate and crystallize.

Remarks. This salt forms green needles, is deliquescent, soluble in alcohol, and when heated, (under 400°,) loses its water, and becomes anhydrous chloride of copper, and assumes the form of a yellow powder. The first of these preparations is sometimes called the protochloride or muriate; the second the deutochloride.

COPPER, CHROMATE OF. *Prep.* Precipitate a salt of copper, with neutral chromate of potash; or dissolve hydrated peroxide or carbonate of copper in chromic acid. Caustic ammonia dissolves this salt, forming a magnificent dark-green liquid, from which, by the admixture of spirit of wine, ammonio-chromate of copper, or cupro-chromate of ammonia, is disengaged in the form of a powder of a splendid, rather dark-green appearance. The readiest way of preparing this permanent and beautiful color, is to add solution of chromate of potash to ammoniacal sulphate of copper.

COPPER, FEATHER-SHOT. *Prep.* Melted copper, poured in a small stream into cold water. It forms small pieces, with a feathered edge, hence the name. It is used to make solution of copper.

COPPER GREEN. *Syn.* OXY-CHLORIDE OF COPPER. BREMEN GREEN. BRUNSWICK DITTO. FRIEZLAND DITTO. *Prep* Pour a saturated solution of muriate of ammonia over copper filings or shreds in a close vessel, keeping the mixture in a warm place, and adding more of the solution from time to time, till 3 parts of muriate and 2 of copper have been used. After standing a few weeks, the pigment is to be separated from the unoxidized copper, by washing through a sieve; and then it is to be well washed, and dried slowly in the shade. This green is almost always adulterated with ceruse, which improves the color.

Remarks. A mixture of cream-tartrate, or carbonate of copper, with carbonate of lime and magnesia, is also sold under the name of Brunswick green.

COPPER, IN FINE POWDER. *Prep.* A solution of sulphate of copper is heated to the boiling-point, and precipitated with distilled zinc. The precipitated copper is then separated from the adherent zinc by diluted sulphuric acid, and dried by exposure to a moderate temperature. From recently precipitated chloride of silver, an exceedingly fine silver-dust may also be obtained by boiling it with water, acidulated with sulphuric acid and zinc. (Boettger's Beitrage.)

COPPER, IODIDE OF. I. (*Iodide.*) When iodide of potassium is added to a solution of a salt of copper, a diniodide of copper falls down, and an iodide remains in solution. It is but little known.

II. (*Diniodide.*) To a solution of 4 parts of protosulphate of copper, and 5 parts of protosulphate of iron, add a solution of iodide of potassium, wash and dry the precipitate.

Remarks. The last preparation is that commonly known in trade by the name of iodide of copper.

COPPER, OXIDES OF. I. (*Black Oxide. Syn. Protoxide of Copper.*) *Prep.* This may be formed by calcining metallic copper, nitrate of copper, or the hydrate, thrown down from solutions of the salts of copper by means of pure potassa. This preparation was formerly called the deutoxide of copper. It is not changed by heat, but readily gives out its oxygen when heated with combustible matter; hence its general use in organic analysis for supplying oxygen.

II. (*Red Oxide. Syn. Dioxide of Copper.*) *Prep. a.* Mix 31·6 parts of copper filings with 39·6 parts of black oxide of copper, and heat them together in a covered crucible.

b. Boil a solution of the acetate of protoxide of copper with sugar; collect the red powder, wash it with water, and dry it.

c. Mix dichloride of copper with an equal weight of carbonate of soda, and fuse it at a low red heat, then well wash the mass with water, and dry the red powder.

d. Mix 100 parts of sulphate of copper with 57 parts of carbonate of soda, (both in crystals,) and fuse them at a gentle heat; cool, pulverize, add 25 parts of fine copper filings, ram the mixture into a crucible, cover it over, and expose it for 20 minutes to a white heat.

e. A saturated solution of sugar of milk, containing some carbonate of soda, is poured over recently prepared moist hydrated oxide of copper, and heated to boiling. A dark orange-colored precipitate of hydrate of protoxide of copper soon appears, from which saccharine matter is remov by washing in distilled water, and then dried.

f. (*Magnificently red anhydrous protoxide copper.*) A solution of 27 parts of cane-sugar, 60 parts of water, is poured over 9 parts of h drate of oxide of copper, (weighed in the co pressed and still moist state;) a solution of parts of caustic potassa, in 60 parts of water, added; the whole mass well agitated together the ordinary temperatures, and strained throu linen. If the dark-blue liquid, after being pass through the strainer, is heated, continually stirri over the water-bath, anhydrous protoxide of co per is disengaged, and the liquid becomes colorle (Boettger's Beitrage.)

Remarks. Red oxide of copper resembles me tallic copper in appearance. It is used as a pi ment and a bronze. By heat it is converted in the black oxide. With ammonia it forms a col less solution, but rapidly becomes blue from th action of the air. This preparation was formerl called *protoxide of copper.*

III. (*Peroxide.*) Formed by the action of per oxide of hydrogen water, on the hydrated blac oxide. (Thenard.) It is very liable to spontaneous decomposition.

Remarks. According to the opinions of Berze lius, Thompson, Liebig, Gregory, and others, th eq of copper is 31·6, and consequently the re oxide is a sub- or di-oxide, and the black the oxi or protoxide. The former containing 63·2 part of copper and 8 of oxygen, and the latter 31·6 of copper and 8 of oxygen. But if the eq. of coppe be taken at 63·2, as is done by some persons, th first of these preparations must be regarded as th protoxide, and the second as the deuto- or bin oxide. The latter terms were generally applied to them in chemical works, until within the las few years. The black oxide has also been calle the *peroxide.* This explanation is called for, t prevent the tyro in chemistry mistaking the one preparation for the other.

COPPER, SALTS OF. These are more or less poisonous, and may be recognised in the manner as described under the article COPPER.

COPPER VESSELS. Culinary and pharmaceutical vessels are very commonly made of copper, but too much caution cannot be exercised in their employment. Acid sirups, vegetable juices, aqueous extracts, soups, stews, &c., prepared in copper saucepans, or boilers, receive a metallic contamination proportional to the length of time they are exposed to the action of the metal. Such vessels are frequently tinned, for the purpose of protecting the copper from contact with their contents, but this film of tin is necessarily very thin, and rubs off by constant use. When acids or acidulous fluids are boiled in vessels of imperfectly tinned copper, a portion of the tin is taken up by the liquid, and deposited upon the abraded or exposed part, thus protecting the copper from the farther action of the menstruum; but the protective power of such a deposite is limited, and it has been proved that when a coating of metal is extremely thin, though appearing quite perfect to the eye, it has a certain porosity, that permits the action of acids on the metal beneath. This has been proved to be the case, even when the deposite is of silver. (Warrington.) When copper vessels

allowed to remain wet or dirty, and especially sy, a poisonous green matter forms upon their ce, somewhat similar to verdigris, and if ar- prepared in them without their being first rly cleaned, be taken as food, serious conse- es may ensue. Cases of poisoning from this are frequently met with, and instances of ing following the use of such articles are still common. I have known extracts prepared pper pans deposite a coating of that metal the knives used to stir them, and the ashes the inspissated juices of fresh vegetables, and cially the pulps of fruit, prepared in vessels of same metal, have exhibited the presence of per on the application of chemical tests. The t wholesome material for culinary utensils is sheet iron or tin plate, which is very durable pt clean and dry when not in use. Copper els of every kind should be cleaned out, im- diately before use, even though they may appear to want it, and on no account should y be employed for any fluids that are the least idous, or that are required to remain long in m.

COPPERAS. *Syn.* Green Copperas. Green triol. Vitriol of Iron. Commercial Sul- te of Iron. Crude sulphate of iron, made by wing iron pyrites to effloresce in the air, wash- out the salt, boiling along with scraps of old , evaporating and crystallizing.

COPPERAS, CALCINED. *Syn.* Dried phate of Iron. Calcined ditto. *Prep.* Heat en vitriol in an unglazed earthen pot, or spread t in a warm situation, until it becomes white d dry. *Use.* It is astringent and drying, and is etimes used in making ink, and in dyeing.

CORAL, FACTITIOUS. Prepared chalk d, colored with a little sesquioxide of iron, or pink, and passed through a sieve. This is al- st universally sold by the druggists for powdered al. It possesses similar properties.

CORDIAL, (in Medicine.) Any warm stim- nt that tends to raise the spirits and promote circulation. The principal cordial medicines the aromatized tinctures.

CORDIAL, (in the art of the Rectifier.) matized and sweetened spirit, employed as a erage.

Cordials are prepared by either infusing the aro- atics in the spirit, and drawing off the essence distillation, which is then sweetened, or without tillation, by flavoring the spirit with essential s, or simple digestion on the ingredients, adding gar or sirup, as before. Malt or molasses spirit the kind usually employed, and for this purpose ould be *perfectly flavorless;* as, if this be not e case, the quality of the cordial will be inferior. ectified spirit of wine is generally the most free om flavor, and when reduced to a proper strength ith water, forms the best and purest spirit for rdial liquors. Spirit which has been freed from s own essential oil, by careful rectification, is mmonly called '*pure,*' '*flavorless,*' '*plain,*' or *lent spirit.*' The solid ingredients should be ately pounded or bruised, before digestion in the pirit, and this should be done immediately before tting them into the cask or vat; as, after they e bruised, they rapidly lose their aromatic prop- ties by exposure to the air. The practice of drying the ingredients before pounding them, adopted by some workmen for the mere sake of lessening the labor, cannot be too much avoided, as the least exposure to heat tends to lessen their aromatic properties, which are very volatile. The length of time the ingredients should be digested in the spirit, should never be less than 3 or 4 days, but a longer period is preferable when distil- lation is not employed. In either case, the time allowed for digestion may be advantageously ex- tended to 10 days or a fortnight, and frequent agi- tation should be had recourse to. When essential oils are employed to give the flavor, they should be first dissolved in a little strong alcohol, or recti- fied spirit of wine, so as to make a perfectly trans- parent solution; and when added to the spirit, they should be mixed up with the whole mass as rapidly and as perfectly as possible, by laborious and long-continued agitation. In managing the still, the fire should be proportioned to the ponder- osity of the oil or flavoring, and the receiver should be changed before the faints come over, as the latter are unfit to be mixed with the cordial. The stronger spirit may be reduced to the desired strength by means of *clear* soft water, or the clar- ified sirup used for sweetening. The sugar em- ployed should be of the finest quality, and is pref- erably made into capillaire or sirup before adding it to the aromatized spirit; and this should not be added until the latter has been rendered perfectly fine by filtering or fining. Some spirits, as aniseed, &c., frequently require this treatment, which is best performed by running them through a fine and clean wine-bag, having previously mixed them with a spoonful or two of magnesia. By good management, cordials thus made will be perfectly "clear" and transparent; but should this not be the case, they may be fined with the whites of about 12 or 20 eggs to the hogshead, or by adding a little alum, either alone, or followed by a little carbonate of soda or potassa, both dissolved in wa- ter. In a week or a fortnight the liquor will be clear. (See Clarification.)

A most convenient and easy way of manufac- turing cordials, especially where it is wished to avoid keeping a large stock, is always to keep two casks of sweetened spirit ready prepared, at the strength of 60 or 64 u. p. The one should contain 1 lb. of sugar to the gallon, the other 3 lbs. per gallon. From these may be made spirit of any intermediate sweetness, which may be flavored with any essential oil dissolved in alcohol, or any aromatic spirit, prepared either by digestion or dis- tillation. As a general rule, the concentrated es- sences may be made by dissolving 1 oz. of the es- sential oil in 1 pint of the strongest rectified spirit of wine. This solution should be kept in well- corked bottles, and used by dropping it cautiously into the sweetened spirit, until the desired flavor is produced. During this operation, the cordial should be frequently and violently shaken, to produce a perfect admixture. Should sufficient essence to foul the liquor be added by accident, the transpa- rency may be restored by the addition of a little more spirit, or by clarification.

The most frequent cause of failure in the manu- facture of cordials, is the addition of *too much fla- voring*. Persons unaccustomed to the use of strong aromatics and essential oils, seldom sufficiently es-

timate their power, and consequently, generally add too much of them, and thus not only is the liquor rendered disagreeably high flavored, but the quantity of oil present turns it '*milky,*' or '*foul,*' on the addition of the water. This again is another source of annoyance, as from the consistence or viscidity of the fluid, it is less readily '*fined down*' than unsweetened liquor, and often gives much trouble to clumsy and inexperienced operators. The most certain way to prevent this is to use *too little*, rather than *too much* flavoring; for if the quantity prove insufficient, it may readily be '*brought up,*' even after the cordial is made.

A careful attention to the previous remarks will render this branch of the rectifier's art far more perfect and easy of performance than it is at present, and will, in most cases, produce at *once* a satisfactory article, '*fine, sweet,* and *pleasant.*'

It may be observed, before concluding this short notice, that the majority of cordials may be made with the pure essential oils, of *nearly* equal flavor to those prepared by distillation; and for such as *are colored,* simple digestion of the ingredients is almost universally employed. Inferior lump, or even good brown sugar is used for some dark and strong-flavored articles. Ingredients that are *not volatile,* are, of course, always added after distillation. Though I have said that very excellent cordials may be made *without* distillation, yet the *still* should be always employed to impart the flavor and aroma of volatile aromatics to spirits, when the expense, labor, and time are of no importance compared to the production of a superior article. The strength at which cordials are usually sent out by permits is 60 or 64 u. p.

CORDIAL, ANISEED. *Prep.* I. Aniseed (bruised) 1 lb.; proof spirit 6 gallons; macerate for a week; then distil 5 gallons; add 2 gallons of clear soft water, and 1 gallon of clarified sirup. This will make 8 gallons of cordial 24 u. p., which is as weak as "aniseed" should ever be made. It may be reduced by sweetened water.

II. Instead of distilling off the spirit, merely pass it through a wine-bag, to take off the seed, lower it with clear soft water, and sweeten as before.

III. Instead of 1 lb. of aniseed, add enough of the essential oil, dissolved in spirit of wine, to produce the desired flavor; 2 drachms of the oil is fully equal to 1 lb. of the seeds.

CORDIAL, BILIOUS, (CHAMBERLAIN'S.) An American medicine, prepared from the inner bark of the juglans cinerea, mixed with spices.

CORDIAL FOR CALVES. *Prep.* I. Caraways, powdered, ½ oz.; ginger and carbonate of soda, of each a spoonful; gin or brandy, ¼ of a wineglassful; water 6 oz.

II. Brandy ½ oz.; cow's urine 4 oz.; mix. (Gray.)

Use. As a stimulant for looseness, &c., in calves.

CORDIAL, CARAWAY. *Prep.* Bruised caraway seeds 3 lbs., or, essential oil of caraway 1½ oz.; sugar 56 lbs.; clean spirit, at proof, 40 gallons; water q. s.

Remarks. The addition of 30 drops of oil of cassia, and 20 drops each of essence of lemon and orange-peel, to the above quantity, improves the flavor; also a larger quantity of sugar must used, if the cordial is to be much lowered.

II. Seeds ¼ lb., or oil 1 drachm; proof spiri gallon; sugar 3 lbs.; water q. s. As last.

CORDIAL, CEDRAT. *Prep.* I. Essence cedrat ¼ oz.; dissolve in pure proof spirit 1 gall add water 3 pints, agitate well; draw off 3 qua and add an equal measure of clarified sirup.

Remarks. This is a most delicious cordial.

II. Cut 12 lemons in pieces, and digest in spi of wine 1 gallon; add water 1 quart; draw o gallon, and add an equal weight of capillaire. I ferior to the last.

CORDIAL, CINNAMON. This is seld made with cinnamon, but with either the essen oil, or bark of cassia. It is preferred colored, a therefore may be very well prepared by simple gestion. If the oil be used, 1 dr. will be found be enough for 2 or 3 gallons of spirit. The ad tion of 2 or 3 drops each of essence of lemon a orange peel, with about a spoonful of essence cardamoms to each gallon, will improve it. So persons add to the above quantity 1 drachm cardamom seeds and 1 oz. each of dried oran and lemon peel. 1 oz. of oil of cassia is conside to be equal to 8 lbs. of the buds, or bark. wanted dark it may be colored with burnt sug The quantity of sugar is 1½ lb. to the gallon.

CORDIAL, CITRON. *Prep.* Yellow rind citrons 3 lbs.: orange peel 1 lb.; nutmegs brui 2 oz.; proof spirit 13 gallons; distil . macera add water sufficient, and 2 lbs. of fine lump sug for every gallon of the cordial.

CORDIAL, CLOVE. *Prep.* Bruised clo 1 oz., or essential oil, 1 dr. to every 4 gallons proof spirit. If distilled it should be drawn o with a pretty quick fire. It is preferred of a ve deep color, and is therefore strongly colored w poppy-flowers or cochineal, or more commo with brandy coloring, or red sanders wood. should have 3 lbs. of sugar to the gallon, and t need not be very fine. The addition of 1 drach of bruised pimento, or 5 drops of the oil for eve ounce of cloves, improves this cordial.

CORDIAL, CORIANDER. *Prep.* 1 lb. coriander seeds; 1 oz. of caraways, and the p and juice of 1 orange to every 3 gallons of pro spirit.

CORDIAL, GOLD. *Prep.* Angelica ro sliced, 1 lb.: raisins ½ lb.; coriander seeds 2 o caraway seeds and cassia, of each 1½ oz.; clo ½ oz.; figs and sliced liquorice root, of each 4 o proof spirit 3 gallons; water 1 gallon. Diges days, and draw off 3 gallons by a gentle heat; this add 8 lbs. of sugar dissolved in 1 quart ea of rose-water and clear soft water, and stee oz. of hay saffron in the liquid until it acquire proper color.

Remarks. The above is the form for a cordi once in much esteem, and which derived its na from a small quantity of gold leaf being added to It is now but little drunk, and this addition seld made.

CORDIAL, GODFREY'S. *Prep.* I. Mo lasses 15 lbs.; distilled water 2¼ gallons; dissolv add oil of sassafras 1 oz. dissolved in rectified spi of wine ½ gallon, bruised ginger ¼ oz.; cloves ¼ o laudanum 8 oz.; macerate for 14 days, and st through flannel.

II. Sassafras chips 1 lb.; ginger bruised 4 oz.; ter 3 gallons; simmer until reduced to 2 gal-; then add treacle 16 lbs., rectified spirits 7 , and laudanum 1 pint.

III. Opium ½ oz.; treacle 5 lbs.; boiling water allon; dissolve, and add rectified spirit ½ pint; of sassafras ½ dr.; cloves, mustard seed, of each ; corianders and caraway seeds, of each 1 dr.; st for a week.

V. Caraway, corianders, and aniseed, of each ; water 6 gallons; distil 5 gallons, and add cle 28 lbs.; mix, then add laudanum 1 quart, oil of sassafras 1 oz. previously dissolved in ified spirit 1 gallon.

Remarks. The above forms are those commonly ent in the drug trade. This cordial is anodyne narcotic, and is commonly given to children bled with wind or colic. Its frequent and ex-ive use has sent many infants prematurely to grave. Gray says, "*It is chiefly used to pre- the crying of children in pain or starving.*" dose is ½ of a teaspoonful and upwards, ac-ng to the age of the child.

CORDIAL, GOUT. *Prep.* Rhubarb, senna, ander seed, sweet fennel seed, and cochineal, ach 2 oz.; liquorice root and saffron, of each 1 ; raisins 2½ lbs.; rectified spirit of wine 2 gal-; digest for 14 days. Used in gout and rheu-ism. *Dose.* 1 tablespoonful to ½ oz. It is atic and slightly laxative.

CORDIAL, HORSE. *Prep.* Compound tinc- of benzoin 1 pint; compound spirit of ammo-, and sweet spirits of nitre, of each 8 oz.; mix; it up in Bateman's bottles, and seal them.

CORDIAL LEMON. *Prep.* Digest 2 oz. of fresh and dried lemon peel, and 1 oz. of orange peel in 1 gallon of proof spirit for a k; strain with expression, add clear soft water educe it to the desired strength, and lump su- in the proportion of 2½ lbs. to 3 lbs. to the gal- The addition of a little orange-flower or rose- er improves it.

CORDIAL, LOVAGE. *Prep.* Fresh roots of ge 2 oz.; fresh roots of celery and sweet fen- of each 1 oz.; essential oil of caraway ¼ oz.; f spirit 3 gallons; digest for 7 days, add wa- 1 gallon; distil off 2½ gallons; add water to e it of the desired strength, and sweeten with sugar. To the above ingredients some per- add, before distillation, ¾ oz. of fresh valerian and 1 drachm of oil of savine.

CORDIAL, NERVOUS. (Brodum's.) *Prep.* tures of gentian, calumba, cardamoms, and hona, compound spirits of lavender, and steel e, of each equal parts. Tonic and stomachic.

CORDIAL, ORANGE. Like lemon cordial, fresh orange peel to the gallon.

CORDIAL, PEPPERMINT. *Syn.* Sports-'s Cordial. Eau de Chasseurs. *Prep.* Add sh oil of peppermint 2 oz. to rectified spirit of 1 quart, agitate well in a corked bottle, ca- of holding 3 pints or more, then pour it into sk having a capacity of upwards of 100 gal-; add 36 gallons of perfectly white and fla- proof spirit, agitate well for 10 minutes, add 2 cwt. of the best refined lump sugar, ously dissolved in twice its weight of pure ed rain water; rummage well, and further sufficient clear rain water to make up the whole quantity to exactly 100 gallons; again rummage well; add 2 oz. alum, dissolved in 1 quart of rain water, and a third time agitate for 15 minutes, after which put in the bung and let it stand for a fortnight, when it will be fit for sale.

Remarks. The above produces a beautiful article, provided the oil of peppermint be of good quality, the sugar double refined and stove-dried, and the cask one that will not give color. To ensure the *first*, the oil should be purchased of some known respectable dealer. That prepared at Mitcham, Surrey, and hence called "*Mitcham oil of peppermint*," is not only the strongest but best flavored, and though more than double the price of the foreign oil, is, in the long run, much the cheapest. *The sugar* should be sufficiently pure to dissolve in a wine glassful of clear soft water, without injuring its *transparency*, and the *cask* should be a fresh-emptied gin pipe, or one properly prepared for gin, as if it give color it will spoil the cordial. If these particulars be attended to, the product will be a *clear transparent* liquor as soon as made, and will not require fining; but should there be the slightest opacity, some alum may be added as above, which will clear it down. Some persons add more oil of peppermint, others less, than the quantity I have ordered, but this, as well as the weight of sugar, must depend upon the taste of the purchasers, and the price the liquor is to be sold at. The product is 100 gallons of cordial at 64 u. p., which is the strongest usually sent out. A similar plan may be followed for the manufacture of any other cordial liquor, the same principles and operations being common to all.

CORDIAL, Sir WALTER RALEIGH'S. *Syn.* Sir W. Raleigh's Confection. Aromatic do. *Prep.* Fresh summits of rosemary and juniper berries, of each 1 lb.; cardamom seeds, zedoary, and saffron, of each ½ lb.; proof spirit 1½ gallons; digest for a fortnight, express and strain; evaporate to 2½ lbs. and add Gascoigne's powder 1 lb.; cinnamon and nutmegs, of each 2 oz.; cloves 1 oz., white sugar 2 lbs., mix well together.

Remarks. The above formula is that for the original aromatic confection. Sir Walter Raleigh's own receipt was far more complicated.

CORDIAL, SPORTSMAN'S. *Syn.* Eau de Chasseurs. *Prep.* Peppermint water and rectified spirits of wine, of each 1 pint; lump sugar ½ lb. Dissolve the sugar in the water and add it to the spirit.

CORDIAL, WARNER'S. *Prep.* Rhubarb ℥j; senna ℥iss; saffron ʒj; liquorice root ʒiv; raisins lb. j; rectified spirit lb. iij: digest for a fortnight. Laxative.

CORK. *Syn.* Corker. The lichen omphalodes made into balls. Used to dye wool.

CORKS. The common practice of employing inferior corks for the purpose of stopping the mouths of bottles, is often productive of considerable loss, from the air being only partially excluded, and the contents suffering in consequence. I once saw a large "*bin*" of valuable wine become, in less than a year, little better than sour Cape, from the parsimony of its owner on this point, and I have frequently had to regret the loss of valuable chemical preparations from a similar cause. The best corks are those called "*velvet corks*," and of these the finest qualities are imported from France.

CORNS. Round, horny, cutaneous extuberances, with central nuclei, very sensitive at the base, arising from continued pressure over the projection of the bones, from *tight* or stiff shoes or boots. Corns are of two kinds, hard and soft. The former grow on the exposed portions of the joints, the latter between the toes.

Treat. First soak the feet in warm water for a few minutes, then pare the corns as close as possible with a sharp knife, taking care not to make them bleed. They may now be touched over with a little lunar caustic, or nitric acid. The former is used by merely rubbing it on the corns, previously *slightly moistened* with water; the latter by moistening them with it, by means of a strip of wood, or preferably a rod of glass. This treatment adopted every other day for 10 or 12 days, accompanied by the use of *soft, loose shoes,* will generally effect a cure. Concentrated acetic acid may be used instead of nitric acid, and is preferred by some persons from not staining the skin, but it is less active, and requires to be more frequently applied. It has been recommended to remove large corns by ligatures of silk, applied as close to the base as possible, and tightened daily until they drop off; but this plan is tedious, and is not always successful. Another mode of extirpation is the application of a small blister, which will frequently raise them with the skin out of their beds. In this case the exposed surface must be dressed with a little simple ointment. Soft corns may also be easily removed by applying ivy leaf previously soaked in strong vinegar, changing the piece every morning; or by placing a dressing of soap cerate, spread on a bit of lint or old rag, between the toes. One of the simplest and best remedies for hard corns, and which has lately received the sanction of high medical authority, is to wear upon the toe or part affected a small circular pi of soft leather, or still better, a piece of amad spread with diachylon or other emollient plas and having a hole cut in its centre the size of corn. (Sir B. Brodie.) By this means the press of the boot or shoe is equalized, and the corn p tected.

Prevention. This consists in keeping the f clean, by frequent ablutions with warm water, the use of *easy, soft shoes or boots.* Without latter precaution, corns will generally return, ev after they appear to have been perfectly remov

CORNS, POPULAR REMEDIES FOR. (*Lotion.*) Sal ammoniac 1 oz., spirit 4 oz.; dissol Moisten the corn with this lotion every morni and evening.

II. (*Powder.*) Savine leaves 2 oz.; verdigri oz.; red precipitate ½ oz.; all in powder. Mix. A plied by means of a piece of rag to the corn night

III. (*Plaster.*) White diachylon and yel rosin, of each 2 oz.; melt and add finely-powde verdigris 1 oz. For use, spread it on paper, lin or leather, and apply a small piece to the corn.

CORN SOLVENT, SIR H. DAVY'S. *Pr* Potash 2 parts, salt sorrel 1 part; each in f powder. Mix and lay a small quantity on t corn for four or five successive nights, binding it with a rag.

CORRECTING PROOFS. (IN TYPOGRAPH The operation of marking on the proof sheets o work any errors of orthography, punctuation, a rangement, or language, they may contain, a also any alterations that may appear necess The following specimen will explain the meth generally adopted for this purpose, and with a li attention will enable any person to superintend work through the press, as far, at least, as d pends upon the correction of the proofs:

but occur in greater quantity when damaged grain is employed to make the mash. It has been proposed to prevent, or at least to lessen the production of this oil, by not pushing the attenuation of the wort too far, or by the addition of a certain quantity of tartaric acid or bitartrate of potassa to the wort before submitting it to fermentation. The best means of depriving spirits of these, or other substances of a similar nature, is to largely dilute them with water, and to draw them over at a gentle heat. Agitation with olive oil, decantation, dilution with a large quantity of water, and redistillation at a moderate heat, have also been recommended. An excellent method, frequently adopted to purify nauseous whiskey distilled from corn-spirit, is filtration through a series of 6 or 8 vessels, filled with *newly-burnt* and coarsely-powdered charcoal. This plan succeeds perfectly with moderately diluted spirits.

On the Continent the peculiar taste which grain and potato oils impart to spirit is termed "*fusel.*" To remove this, about 10 per cent. of common vinegar, and a *very little* sulphuric acid are added, and well mixed by agitation. The spirit is next allowed to repose for a few days, and then distilled. A solution of chloride of lime is also employed for the same purpose, and in the same way. In both the above cases, a species of ether is formed which possesses a very agreeable odor. In the first case, acetate of oxide of amylol is produced, which has so pleasant a taste and smell of fruit, that "it may be employed for perfuming apartments and making ratifias." The chloride of amylol has also a pleasant ethereal smell and taste. The affinity of the hydrated oxide of amylol (fuselöl) for acetic acid is so great, that they readily unite without the intervention of a mineral acid. (Doebereiner.) Thus, the oil of vitriol mentioned above, though always used in practice, might be omitted without any disadvantage.

It is often of the utmost importance to brewers, wine-merchants, sugar-refiners, &c., to be able to lessen the activity of the vinous fermentation, or to stop it altogether, or to prevent its accession to sirups or saccharine and vegetable solutions. The nature of the animalized matter forming ferment, the presence of which is necessary to fermentation, will readily suggest the proper means to be employed in such cases. Whatever will still the motion of the molecules of the nitrogenous matter forming the ferment, will render them inoperative as exciters of fermentation. Among the simplest means of effecting this object, and such as admit of easy practical application, may be mentioned exposure to either *cold* or *heat.* At a temperature below about 50° F., the acetous fermentation ceases altogether, and the alcoholic fermentation proceeds with diminished activity as the temperature falls, until at about 38° F. it entirely ceases. In like manner, the rapid increase of the temperature of a fermenting liquid will arrest its fermentation, and is preferable to the action of cold, as it is of easier application, and perfectly precipitates the ferment in an inert state. For this purpose, a temperature of about 180 or 200° is preferable, or even that of boiling water may be employed with advantage. In practice, fluids are commonly raised to their boiling point for this purpose, or are submitted to the heat of a water-bath, (207½° F.) In this way the fermentation of sirups and vegetable solutions and juices is usually arrested in the pharmaceutical laboratory.

Among substances that may be added to liquids to arrest fermentation, the most active are—the volatile oil of mustard, coarsely-powdered mustard seeds or *pure* flour of mustard, sulphurous acid or the fumes of burning sulphur, sulphuric acid, sulphite of lime, tincture of catechu, alcohol, strong acetic acid, chlorate of potassa, bruised horseradish, garlic, and cloves, and their essential oils, and all the other volatile oils that contain sulphur, and most of the salts that readily part with their oxygen. All the above arrest fermentation, and render yeast inoperative, and they possess this power nearly in the order in which they stand above. In practice, mustard, the fumes of burning sulphur, and sulphite of lime, are those most adapted for beer, cider, wines, sirups, &c.; but some of the others are occasionally used, though less active. For arresting or preventing the fermentation of the vegetable juices and solutions, and the *medicated* sirups employed in pharmacy, *mustard seed, or this with a little bruised cloves,* should alone be used, as the addition of acids or salts would lead to the decomposition of their active principles. For this reason such liquids should be kept in a sufficiently low temperature to prevent fermentation, and should they pass into that state, it should be preferably arrested by the application of heat or cold, as above explained. (See BREAD, BREWING, YEAST, &c.)

3. The *viscous or mucilaginous fermentation,* is that peculiar change which produces the "ropiness" of wine, beer, and other liquors. This species of decomposition is exhibited in the most complete state, when the juices of carrots, onions, beet roots, &c., are fermented at a temperature of from 100° to 120° Fahr. At ordinary temperatures alcohol is formed, but in this case the sugar is converted into mannite, lactic acid, and a peculiar substance which is precipitated as a species of slimy mucilage on the addition of alcohol. Weak solutions of sugar (1 to 20) boiled with yeast or gluten, and kept at a temperature of from 85° to 105° Fahr., readily pass into this kind of fermentation. The best means of arresting this disposition in fermented liquors, is the addition of a little alum or catechu, dissolved in water, or an infusion or decoction of nut galls. A small quantity of sulphurous or sulphuric acid will produce a like effect. When weak sirups are attacked in this way, the best remedy is to heat them to the boiling point.

4. The *acetous fermentation,* or the production of vinegar by the oxidation of alcohol, has been already briefly touched on, under the head ACETIFICATION. It may be here remarked, that this species of fermentation differs from those previously noticed; for whereas they are capable of continuing in vessels *without* access of air, when once excited, *this* is immediately stopped when the air is *excluded,* and under ordinary circumstances proceeds with a degree of rapidity proportionate to the amount of surface exposed to the action of atmospheric oxygen. It also differs from the alcoholic fermentation by the products being formed, not only by a new grouping of the elements of the substance undergoing decomposition, but by means

CORROSION, PREVENTION OF. The best means of preventing the corrosion of metals is first to dip the articles into very dilute nitric acid, and afterwards to immerse them in linseed oil, allowing the superfluity of oil to drain off; they are by this means very effectively preserved from rust or oxidation. (W. J. Lander.)

COSMETICS. (*Cosmetica*, from Κοσμέω, *I adorn.*) Any external application used for the purpose of preserving or restoring the beauty. The term is generally understood to refer to substances applied to the cuticle, to improve the color and clearness of the complexion; but some writers have included under this head, every topical application to promote the personal appearance. Hence cosmetics may be divided into three kinds, viz.:—*Cutaneous cosmetics*, or those applied to the skin; *hair cosmetics*, or such as are employed to promote the growth and beauty of the hair; and *teeth cosmetics*, or such as are used to cleanse and beautify the teeth. The present article will be confined to a short notice of the first of these divisions, referring the reader to the separate heads —*hair dyes, pomatums, pommades, depilatories, dentifrices, tooth powders, &c.*, for information respecting the remainder.

CUTANEOUS COSMETICS. The most simple and universally employed cosmetics are soap and water, which at once cleanse and soften the skin. Soap containing a full proportion of alkali, exercises a solvent power upon the cuticle, a minute portion of which it dissolves; but when it contains a small preponderance of oily matter, as the principal part of the milder toilet soaps now do, it mechanically softens the skin and promotes its smoothness. Almond, Naples, and Castile soaps are esteemed for these properties, and milk of roses, cold cream, and almond powder, (paste,) are used for a similar purpose. To produce an opposite effect, and to harden the cuticle, spirits, astringents, acids, and astringent salts are commonly employed. The frequent use of hard water has a similar effect. The application of these articles is generally for the purpose of strengthening or preserving any given part against the action of cold, moisture, &c.; as the lips, or mammæ, from chapping, or the hands from contracting chilblains; but in this respect, oils, pommades, and other oleaginous bodies, are preferable.

Another class of cutaneous cosmetics are employed to remove freckles and eruptions. Among the most innocent and valuable of these, is Gowland's lotion, which has long been a popular article, and deservedly so, for it not only tends to impart a delightful softness to the skin, but is a most valuable remedy for many obstinate eruptive diseases, which frequently resist the usual methods of treatment. Bitter almonds have been recommended to remove freckles, (Celsus,) but moistening them with a lotion made by mixing 1 oz. of rectified spirit of wine, and a teaspoonful of muriatic acid, with 7 or 8 oz. of water, is said to do this more effectually. A safe and excellent cosmetic is, an infusion of horseradish in cold milk. (Withering.)

Skin paints and stains are employed to give an artificial bloom, or delicacy to the skin. Rouge and carmine are the articles most generally used to communicate a red color. The former is the only cosmetic that can be employed, without i jury, to brighten a lady's complexion. The latt though possessing unrivalled beauty, is apt to i part a *sallowness* to the skin by frequent u Starch powder is employed to impart a white tu and is perfectly harmless. The American ladi who are very fond of painting their necks whit use finely-powdered magnesia, which is anoth very innocent substance. Several metallic co pounds, as trisnitrate, subchloride, and oxide bismuth, (pearl white, Fard's white, &c.,) carb nate of lead, (flake white,) white precipitate, &c are frequently used to revive faded complexion but they are not only injurious to the skin, but a as poisons, if taken up by the absorbents. Tri nitrate of bismuth, (pearl white,) probably t least injurious of these articles, has caused spa modic tremblings of the muscles of the face, en ing in paralysis. (Vogt. Pharm.) The employme of liquid preparations, containing sugar of lea which are commonly sold under the name of mi of roses, cream of roses, &c., is equally injurio Another disadvantage of these white metall preparations is, that they readily turn black, wh exposed, to the action of sulphureted hydrog gas, or the vapors of sulphur, which frequent escape into the apartment from coal fires. The are many instances recorded, of a whole compa being suddenly alarmed, by the pearly complexi of one of its belles being suddenly transform into a sickly gray or black. A friend of the wr ter's was once startled at a Christmas party b observing the one side of a lady's face and nec which was exposed to the fire, become discolo in this way, and was so amused on learning t cause, that he has since played two or three jo of the kind on some petulant old ladies, remar able for the great attention they pay to their to let. In conclusion it may be remarked, that t best *purifiers of the skin* are soap and wat followed by the use of a *coarse* cloth, in oppo tion to the *costly* and *soft diapers* that are co monly employed; and the best *beautifiers*, HEALTH, EXERCISE, and GOOD TEMPER.

COSMETIC, SIMPLE. *Prep.* Soft soa lb.; melt over a slow fire with a gill of sweet add half a teacupful of fine sand, and stir mixture together until cold. The shelly sea- sifted from the shells, has been found better that which has no shells.

Remarks. This simple cosmetic has, for se years past, been used by many ladies who ar markable for the delicate softness and whit of their hands, which they, in a great mea attribute to the use of it. Its cheapness is a recommendation.

COUGH. The sudden and violent exp of air from the lungs. It is generally sym matic of other affections, but is sometimes idi thic. Many cases of cough depend upon th tension of catarrh to the trachea and bron which thus become loaded with mucus or phl which they endeavor to throw off by the co sive effort called coughing. In some cases caused by a vitiation and inspissation of the s tions, arising from the imperfect action of th sorbents; this is the common cause of the cough of old people. Idiopathic cough is not sidered dangerous in itself, or while runnin

regular course, but it is often productive of most serious consequences, by superinducing the inflammation of some organ, or laying the foundation of phthisis.

Cough is sometimes attended by copious expectoration, and at other times exists without any; it has hence been distinguished into *moist* or *mucous* cough, and *dry* cough.

Treat. The treatment of common catarrhal cough consists in allaying the irritation as much as possible, by demulcents and expectorants, as mucilaginous drinks and lozenges, which act upon the glottis, and sympathetically upon the trachea and bronchiæ. Among the first may be mentioned, almond milk, barley water, refined Spanish juice, gum arabic, and a mixture of the last two made into lozenges; among the second, the most innocent and convenient is ipecacuanha, in the shape of lozenges, 2 or 3 of which may be sucked whenever the cough is troublesome. A light diet should be adopted, the bowels kept *slightly* relaxed by mild aperients, and a mild and equable temperature sought as much as possible. When this plan does not succeed, recourse may be had to an emetic, followed by small doses of Dover's powders, and extract or tincture of henbane, or squill pill. When a cough is troublesome at night, and unattended with fever, a small dose of laudanum, or tincture of henbane, taken on going to rest, will generally procure sleep. In the treatment of dry cough the more stimulating expectorants are useful, as garlic, ammoniacum, styrac, and benzoin, combined with narcotics and sedatives, as henbane, hemlock, and opium. A diaphoretic opiate is also very useful, especially in the cough of old people.

COUGH, POPULAR REMEDIES FOR. I. (*Draughts.*) *a.* Sirup of poppies 1 dessert-spoonful; antimonial wine 20 drops; mix for a dose, to be taken in a little warm tea on going to bed. *b.* Laudanum 30 drops; vinegar and honey, of each, a dessert-spoonful; ipecacuanha wine 25 drops; mix for one dose, as last.

II. (*Emulsion.*) Milk of almonds 4 oz.; sirup of squills and tolu, of each, 1 oz.; mix. *Dose.* A tablespoonful every 2 hours.

III. (*Mixtures.*) *a.* Tincture of tolu ½ oz.; paregoric elixir and tincture of squills, of each, ½ oz.; sirup of white poppies 1 oz.; mix. *Dose.* 1 teaspoonful in barley water, whenever the cough is troublesome. *b.* Milk of ammoniacum 4 oz.; sirup of squills 2 oz.; mix. A tablespoonful 3 or 4 times daily, for the cough of old persons. *c.* (*Dr. Munro's.*) Paregoric ½ oz.; sulphuric ether and tincture of tolu, of each, ¼ oz.; mix. *Dose.* A teaspoonful night and morning, or when the cough is troublesome, in a little warm water. *d.* (*Dr. Radcliff's.*) Sirup of poppies, sirup of squills, and paregoric, of each, ½ oz.; mix. *Dose.* As last.

COUMARINE. The fragrant volatile principle of the tonka bean, the diptera odorata of Wildenow. It is dissolved out by ether, and purified by alcohol. It crystalizes in small prisms.

COWHAGE. *Syn.* COWITCH. DOLICHI PUBES. The down which grows upon the pods of the mucuna pruriens. (Dolichos pruriens.) It occasions violent itching, when it comes in contact with the skin, which can only be allayed by a solution of given vitriol or oil. It is frequently administered as a vermifuge, made into a confection, by scraping the hair off a pod into treacle, sirup, or honey, for a morning dose, which is repeated for 3 or 4 successive days, followed by a brisk purge.

COWS, MILCH, (CHOICE OF.) As to a choice of breeds for a private family, none in England, (says Mr. Lawrence,) probably combine so many advantages as the Suffolk dun-cows. They excel both in quantity and quality of milk; they feed well after they become barren; they are small-sized, and polled or hornless; the last a great convenience. The horns of cows which butt and gore others, should be immediately broad tipped. There is a breed of polled Yorkshire, or Holderness cows, some of them of middling size, great milkers, and well adapted to the use of families, where a great quantity of milk is required, and where price is no object, and food in plenty. If richer milk and a comparison of the two famous breeds be desired, one of each may be selected, namely, the last mentioned, and the other of the midland county, or long-horned species. Color is so far no object, that neither a good cow nor a good horse can be of a bad color; nevertheless, in an ornamental view, the sheeted and pied stock of the Yorkshire shorthorns make a picturesque figure in the grounds.

The Alderney cows yield rich milk upon less food than larger stock, but are seldom large milkers, and are particularly scanty of produce in the winter season. They are, besides, worth little or nothing as barreners, not only on account of their small size, but their inaptitude to take on fat, and the ordinary quality of their beef.

Feeding. There is nothing equal to rich pasturage for milch cows, but at such seasons, and during such weather that this cannot be procured, good hay, with turnips, carrots, potatoes, or mangel-wurzel, must be given instead, along with a sufficient quantity of clean water. The principal cowkeepers of the metropolis have dairy-farms in the suburbs, where the animals are turned out a portion of every day in the year, except during heavy rains, or when the ground is covered with snow. They are also well supplied with brewers' grains, tares, beet-root, &c., and great care is taken that they get fresh air, and exercise sufficient for their health. Such cows yield a large quantity of wholesome milk, very different to much that is sold in London, obtained from cows kept in stables, cellars, and other confined situations, and which are seldom supplied with green food. It has lately been shown by Boussingault, that mangel-wurzel, so commonly used for feeding cattle, is insufficient as an article of food. He found that a cow fed on this substance ceases to give her usual quantity of milk, and that even when other food was given along with it, the animal yielded less than her ordinary quantity. Before giving turnips to cows, the rotten or bad ones should be picked out, as it is said that even the presence of a single damaged one will flavor the milk, and perhaps spoil a whole dairy of cheese or butter.

Economy of a cow. The annual consumption of food per cow, if turned to grass, is from an acre to an acre and a half in the summer, and from a ton to a ton and a half of hay in the winter. A cow may be allowed 2 pecks of carrots

perceive any good effects to result from its administration.

COPAIBIC ACID. *Syn.* Capivic Acid. The yellow brittle resin of balsam of copaiba. It is prepared by digesting the resin (left after distilling the oil from the balsam) in alcohol, which dissolves the acid resin, but leaves the viscid one. It may be purified by re-solution in alcohol. It forms about 50% of the balsam.

Prop. An amber-colored, brittle, semi-crystalline, resinous substance, soluble in alcohol, ether, and oils, reddens litmus paper, and forms salts with the bases, called copaivates. These may generally be made by dropping into a solution of the acid in alcohol, an alcoholic solution of a soluble salt of the base. The copaivates of potash, soda, and ammonia are easily prepared, by adding to an alcoholic solution of the acid another of the pure alkali, until it be neutralized, when the salts may be obtained by careful evaporation. Copaivate of silver is formed by neutralizing the acid with nitrate of silver, both being dissolved in alcohol, and then adding a little liquor of ammonia, when a white crystalline precipitate will subside. The copaivates of lead, lime, and iron, as well as several others, may be made in a similar manner.

Copaivate of magnesia may be made by adding copaivate of potassa to a solution of epsom salts. All these salts are easily decomposed by acids.

COPAL. *Syn.* Gum Copal. A resinous substance, which exudes spontaneously from the Rhus copallinum, and the Elæocarpus copalifer. When of good quality, it is too hard to be scratched by the nail, and has a conchoidal fracture. It dissolves with difficulty, and this, combined with its extreme hardness, renders it very valuable for making varnishes.

Solvents. I. *Caoutchoucine;* sparingly. II. Equal parts of *caoutchoucine* and *alcohol*, of ·825; freely soluble in the cold. III. *Absolute alcohol*, added gradually to the copal, previously rendered gelatinous by water of ammonia, assisting the union with heat. IV. *Alcohol* added to the copal, previously softened with ether. V. *Absolute alcohol* 1½ parts, digested on copal 1 part for 24 hours. (Unverdorben.) VI. *Alcohol*, to which a little camphor has been added. VII. *Ether;* and this solution may be diluted with alcohol. VIII. *Oils of rosemary* and *lavender*, (spike;) too expensive for general use. IX. *Copal*, heated until it fuses, acquires the property of dissolving in turpentine and alcohol. X. *Copal*, reduced to powder and exposed for some time to the air, also becomes soluble in alcohol and turpentine. XI. *Drying linseed oil*, at nearly the boiling point, dissolves copal, and will bear dilution with spirits of turpentine as soon as it has cooled sufficiently. This is the common way of making copal varnish. XII. *Ammonia* enables oil of turpentine to dissolve copal; but it requires such nice management of the fire, that it seldom succeeds completely. (Lewis.) XIII. *Powdered copal*, triturated with a little camphor, softens and becomes a coherent mass; and camphor, added either to alcohol or oil of turpentine, renders it a solvent of copal. ½ oz. of camphor is sufficient for 1 quart of oil of turpentine, which should be of the best quality; and the copal, about the size of a large walnut, should be broken into very small pieces, but not reduced to a fine powder. The mixture should be set on a fire so brisk as to make it boil almost immediately The vessel should be of tin or other metal, strong, shaped like a wine-bottle with a long neck, and capable of holding 2 quarts. The mouth should be stopped with a cork, in which a notch is cut to prevent the vessel from bursting. (Sheldrake.) XIV. A good varnish may be made by pouring upon the purest lumps of copal, reduced to a fine mass in a mortar, colorless spirits of turpentine, to about one third higher than the copal, and triturating the mixture occasionally in the course of the day. Next morning it may be poured off into a bottle for use. Successive portions of oil of turpentine may thus be worked with the same copal mass. (Varley, Tilloch's Mag. 51.)

⁂ In all the above cases the copal should be reduced to a *coarse* powder. A *fine* powder is apt to stick together and form hard lumps. The solution of copal, even in its most ready solvents, is attended with some difficulty, and frequently miscarries in the hands of the inexperienced. A mixture of caoutchoucine and alcohol (as in No. II.) is an exception.

COPAL, MELTED. Obtained by holding the gum before a good fire, so that as soon as the copal melts, it may drop into a pan of water: a kind of oil separates from it, and the copal becomes soluble in spirits of wine, and still more so if the melting is repeated.

COPAL, POWDERED. Copal reduced to powder and exposed to the air in a thin stratum, on sieves covered with paper, for 3 or 4 months. Soluble in alcohol.

COPPER. (From *cuprum*, a corruption of κύπρος, from the island of Cyprus, whence it was formerly brought.) A red-colored metal, too well known to require description.

Hist. Copper and its alloys appear to have been known to the most remote ages of antiquity. Brass, an alloy of copper, is mentioned by Moses (Job, xxviii.) upwards of 1600 years before the birth of Christ. (Hales.) This metal is found in the metallic state, and in combination with oxygen, sulphur, acids, and other minerals, and in the organic kingdom, in the ashes of plants, and in the blood of animals. (Sarzeau.) The copper of commerce is principally prepared from copper pyrites, a mixed sulphuret of iron and copper, found in Cornwall, and other parts of the world.

Prep. Copper is only prepared from its ores on the large scale. The copper pyrites is first roasted, and then smelted, by which process "*coarse metal*" is produced; this is again submitted to calcination and smelting, when "*fine metal*" is obtained. It afterwards undergoes the process of refining and toughening.

Prop. This metal is malleable and ductile. It has a specific gravity of 8·8 to 8·9, fuses at about 2000° Fahr., and volatilizes at higher temperatures. It forms numerous compounds, all of which are more or less poisonous.

Char. and Tests. The solutions of copper possess a blue or green color, and yield a blue precipitate with soda or potassa. Ammonia produces a bluish-white precipitato, soluble in an excess of the precipitant, forming a deep blue solution. Prussiate of potash gives a reddish-brown precipitate, sulphureted hydrogen and hydrosulphurets, a black

me. A polished iron plate, immersed in an acidulous solution of copper, becomes coated with that metal.

Estim. The quantity of copper present in any compound, may be estimated by throwing it down from its solution by pure potassa, after which it must be carefully collected, washed, dried, ignited, and weighed. This will give the quantity of the oxide from which its equivalent of metallic copper may be calculated; every 5 parts of the former being (as near as possible) equal to 4 of the latter. Copper may also be precipitated at once in the metallic state, by immersing a piece of polished steel into the solution, but this method will not give very accurate results. Copper may be separated from lead by adding sulphuric acid to the nitric solution, and evaporating to dryness, when water digested on the residuum will dissolve out the sulphate of copper, but leave the sulphate of lead behind. From this solution the oxide of copper may be thrown down as before. Copper may be separated from zinc by sulphureted hydrogen, which will throw down a sulphuret of copper, which may be dissolved in nitric acid, and treated as above.

Uses. The applications of copper in the arts are too well known to require notice. In medicine, 3 or 4 grains of the filings were formerly given in rheumatism, and to prevent hydrophobia.

Ant. Copper in the metallic state appears to be inert, but most of its compounds are poisonous. The antidotes are, the white of egg, milk, or flour mixed with water. Iron filings (Payen, Chevallier, Dumas) and the prussiate of potash have also been recommended. A drachm or more of the latter may be taken dissolved in water, and ½ oz. or more of the former, ad libitum. Sugar has also been proposed as an antidote. (Duval, Postel.)

COPPER, ALLOYS OF. With *zinc* copper forms *brass*; with *tin*, *bronze*, *bell*, and *cannon metal*. An alloy made with 100 parts of copper and 50 of tin, forms *speculum metal*. *White copper* is formed by the addition of metallic arsenic, and *German silver* is a mixture of nickel, zinc, and copper. See these articles in their alphabetical places.

COPPER, ACETATES OF. I. (*Neutral Acetate. Syn. Distilled Verdigris. Binacetate of Copper. Crystallized Verdigris.*) *Prep.* Dissolve verdigris in vinegar, with the aid of heat, and crystallize. It forms dark green or blue crystals.

II. (*Diacetate. Syn. Verdigris. Ærugo.*) Formed by exposing sheets of copper to the vapor of acetic acid, in a warm situation. (See Verdigris.) It forms a green or bluish-green powder.

III. (*Sesquibasic Acetate.*) The blue portion of verdigris, soluble in water.

IV. (*Trisacetate.*) The green insoluble portion of verdigris.

COPPER, ARSENITE OF. *Syn.* Scheele's Green. *Prep.* Mix a solution of 2 parts of sulphate of copper in 44 of water, with a solution of 2 parts of potash of commerce, and 1 of pulverized arsenious acid, also in 44 of water. Both solutions being warm, the first is to be gradually poured into the second. The grass-green insoluble precipitate is to be washed with water.

COPPER, AMMONIURETED. *Syn.* Cupro-sulphate of Ammonia. Ammoniated Copper, (P. E.) *Prep.* (*Ammonio-sulphate of Copper,* P. L.) Sulphate of copper ℥j; sesquicarbonate of ammonia ℥iss. Rub them together until carbonic acid ceases to evolve, then wrap it up in bibulous paper and dry it in the air.

Prop. By heat ammonia is evolved, and oxide of copper remains. Its aqueous solution changes the color of turmeric, and a solution of arsenious acid renders it green. (P. L.)

Uses. Employed in pyrotechny. It has been given in doses of ½ to 5 grs. in chorea, epilepsy, hysteria, &c., but it is principally employed as an injection and as a collyrium, in opacity of the cornea.

Remarks. Great care must be taken in drying this article, as it is apt not only to lose a large portion of its weight, but become of an inferior color. Both the ingredients should be separately reduced to powder before mixing.

COPPER, BEAN-SHOT. *Prep.* Melt copper, and pour it in a small stream into boiling water. It is in small lumps like peas or beans, hence its name.

COPPER, BLANCHED. *Prep.* Fuse copper with $\frac{1}{18}$ of its weight of neutral arsenical salt, under a flux of calcined borax, charcoal, and powdered glass.

COPPER, CARBONATE OF. *Syn.* Dicarbonate of Copper. Mineral Green. *Prep.* Add a solution of carbonate of soda or potassa to a hot solution of protosulphate of copper.

Remarks. The beautiful green mineral called *malachite*, is a hydrated dicarbonate of copper. If the solution of copper in the above formula be employed cold, the precipitate has a bluish-green color. (See Verditer.)

COPPER, CHLORIDES OF. *Prep.* I. (*Subchloride. Syn. Dichloride of Copper. Resin of ditto. White muriate of ditto.*) Distil a mixture of 1 part of copper filings, with two parts of corrosive sublimate.

II. (*Chloride. Syn. Muriate of Copper. Hydrochlorate of ditto. Protochloride of ditto.*) Dissolve protoxide of copper in muriatic acid, evaporate and crystallize.

Remarks. This salt forms green needles, is deliquescent, soluble in alcohol, and when heated, (under 400°,) loses its water, and becomes anhydrous chloride of copper, and assumes the form of a yellow powder. The first of these preparations is sometimes called the protochloride or muriate; the second the deutochloride.

COPPER, CHROMATE OF. *Prep.* Precipitate a salt of copper, with neutral chromate of potash; or dissolve hydrated peroxide or carbonate of copper in chromic acid. Caustic ammonia dissolves this salt, forming a magnificent dark-green liquid, from which, by the admixture of spirit of wine, ammonio-chromate of copper, or cupro-chromate of ammonia, is disengaged in the form of a powder of a splendid, rather dark-green appearance. The readiest way of preparing this permanent and beautiful color, is to add solution of chromate of potash to ammoniacal sulphate of copper.

COPPER, FEATHER-SHOT. *Prep.* Melted copper, poured in a small stream into cold water. It forms small pieces, with a feathered edge, hence the name. It is used to make solution of copper.

sale druggist in the city, produces an excellent article.

II. Hay saffron, cassia, and turmeric, of each 4 oz.; cardamoms 1 oz.; starch 8 oz.; precipitated chalk 2 lbs.; white sugar 4 lbs.; oil of nutmegs 2 drachms; oil of cloves 3 drachms. Reduce the dry ingredients to fine powder, and pass it through an 80 hole sieve, then add the oils, and after well mixing, pass it through a coarse sieve, (about 40 holes to the inch,) to ensure the whole being perfectly mixed.

The following form produces a powder possessing great depth and brilliancy of color.

III. Hay saffron 4 oz.; turmeric 3 oz.; powdered starch 8 oz.; precipitated chalk 2 lbs.; white sugar 4 lbs.; oils of cloves and cassia, of each 3 drachms; oil of nutmegs 2 drachms; essence of cardamoms 1 oz. *Proc.* Boil the saffron and turmeric in 1 gallon of water, placed in a bright copper pan, for 10 minutes, then, without straining, add the chalk, starch, and sugar; mix well, and continue stirring until the mixture becomes quite stiff, then break it up and dry it until fit for powdering. This must be performed in a water or steam bath. To the powder, passed through a fine sieve, as before, the oils and tincture must be added, and after being well mixed, and passed through a coarse sieve, it should be placed in a jar or bottle, and bunged up close.

Remarks. In the wholesale trade this article is kept under two forms: one in powder, as ordered by the College, and commonly called, for distinction sake, "*pulvis confectionis aromaticæ;*" the other mixed up ready for use. In preparing the latter, it is a common plan to make a strong infusion or decoction of the saffron, and to use it to mix up the other ingredients. Some persons follow the method described in the last formula, mixing up the powder to a proper consistence with water before adding the aromatics. When the price of *precipitated* chalk is an objection to its use, *prepared* chalk may be used instead. This confection is cordial, stimulant, and antacid. *Dose.* 10 to 60 grs.

CONFECTION OF BLACK PEPPER. *Syn.* Ward's Paste. *Prep.* (*Confectio Piperis Nigri*, P. L.) Black pepper and elecampane root, of each lb. j; fennel seed lb. iij; honey and white sugar, of each lb. ij; mix.

Remarks. The common practice is to keep the dry ingredients ready mixed in a bottle, and only to add the honey as wanted. The proportions are 2 parts of the latter to 7 of the mixture. The *dose* is 1 to 2 drachms 2 or 3 times a-day, in piles, fistula, &c. It should be persevered in for 2, 3, or 4 months, (Sir B. Brodie;) and as it is apt to accumulate in the bowels, its use should be accompanied by mild aperients. (Pereira.)

CONFECTIONS OF CASSIA. *Syn.* Electuarium Cassiæ, (P. L. 1788.) *Prep.* (*Confectio Cassiæ*, P. L.) Fresh cassia pulp lb. ss.; manna ℥ij; tamarind pulp ℥j; sirup of roses f℥viij. Bruise the manna and dissolve it in the sirup, then add the pulps and evaporate to a proper consistence.

CONFECTION OF HEMLOCK. (Dr. Osborne.) *Prep.* Fresh leaves of hemlock and moist sugar equal parts; beat them to a confection in a mortar.

CONFECTION OF OPIUM. *Syn.* Philonium Romanum, (P. L. 1720.) Ditto Londinense, (P. L. 1745.) Confectio Opiata, (P. L. 1788.) Ditto Opii, (P. L. 1809, and since.) *Prep.* (P. L.) Powdered opium ʒvj; long pepper ℥j; ginger ℥ij; caraways ℥iij; tragacanth ʒij; all in fine powder; sirup f℥xvj. Mix.

Use and Dose. This confection is intended as a substitute for the *mithridate* and *theriaca* of the old Pharmacopœia. It is stimulant and narcotic, and is given in flatulent colic and diarrhœa unaccompanied by fever. The dose is from 15 to 50 grs.

CONFECTION OF ORANGE PEEL. *Syn.* Conserva flavedinis Corticum Aurantiorum, (P. L. 1720 and 1745.) Ditto Corticis exterioris Auranthi Hispalensis, (P. L. 1788.) Ditto Aurantiorum, (P. L. 1824.) Ditto Aurantii, (P. L. 1809 and 1836.) *Prep.* (P. L.) The external rind of the fresh orange, separated by rasping, lb. j; white sugar lb. iij. Beat the rind in a stone mortar with a wooden pestle, then add the powdered sugar, and beat the mixture until the two are perfectly incorporated.

Remarks. This confection is tonic and stomachic, and is principally used as a vehicle for the exhibition of tonic powders.

CONFECTION OF PEPPERMINT. *Prep.* Green peppermint 4 oz.; powdered white sugar 12 oz.; beat them together as last.

Use. Anti-emetic and flatulent. Given in colic, &c., in the form of a bolus, or made into a mixture.

CONFECTION OF THE DOG ROSE. *Syn.* Confection of Hips. Conserva Fructus cynosbati, (P. L. 1720 and 1745.) Ditto Cynosbati, (P. L. 1788.) Ditto Rosæ Caninæ, (P. L. 1809, and since.) *Prep.* (P. L.) Pulp of the dog rose lb. j; powdered refined sugar ℥xx; mix by a gentle heat in an earthen vessel.

II. Pulped hips 2 cwt.; fine white sugar 2½ cwt.; incorporate them without applying heat.

Remarks. Both this and the following confection has a brighter color, if made without heat, or touching metallic vessels. On the small scale it is made by beating the ingredients together in a marble mortar, but in large quantities by grinding in a mill. It is slightly laxative, and is principally used for forming pills. It candies by keeping.

CONFECTION OF THE RED ROSE. *Syn.* Conserva Rosarum Rubrarum, (P. L. 1745.) Ditto Rosæ, (P. L. 1788.) Ditto Rosæ Gallicæ, (P. L. 1809 and 1824.) Confectio Rosæ Gallicæ, (P. L. 1836.) *Prep.* (P. L.) Petals of the red rose lb. j; refined sugar lb. iij; beat the petals in a stone mortar, then add the sugar, and again beat until thoroughly incorporated.

Remarks. On the large scale this is prepared like the confection of hips. It is astringent and tonic, and principally used for forming pills. If taken alone, the dose is 1 to 2 drachms.

CONFECTION OF RUE. *Syn.* Electuarium e Boccis Lauri, (P. L. 1720, 1745.) Confectio Rutæ, (P. L. 1809, and since.) *Prep.* (P. L.) Dried rue, caraway, and laurel berries, of each ℥iss; sagapenum (true) ℥ss; black pepper ʒij; honey ℥xvj. Reduce the dry ingredients to very fine powder, and when wanted for use, make them into a confection with the honey.

Use, &c. It is antispasmodic; in enemas 30 to

60 grs., with half a pint of gruel, for flatulent colic, &c.

CONFECTION OF SCAMMONY. *Syn.* ELECTUARIUM CARYOCOSTINUM, (P. L. 1720.) DITTO E SCAMMONIO, (P L. 1745.) DITTO SCAMMONII, (P. L. 1809 and 1788.) CONFECTIO SCAMMONEÆ, (P. L. 1809 and 1824.) *Prep.* (*Confectio Scammonii* P. L.) Scammony ℥iss; cloves and ginger, of each, ʒvj; oil of caraway fʒss. Reduce the ingredients to a very fine powder, and when wanted for use, make them into a confection with sirup of roses, and lastly add the oil.

Use, &c. Cathartic in doses of 10 to 30 grs.

CONFECTION OF SENNA. *Syn.* LENITIVE ELECTUARY. ELECTUARIUM SENNÆ, (P. L. 1788.) CONFECTIO SENNA, (P. L. 1809, and since.) *Prep.* (P. L.) Senna ℥viij; figs lb. j; pulp of tamarinds, prunes, and cassia, of each, lb. ss.; coriander seeds ℥iv; liquorice ℥iij; sugar lb. iiss; water 3 pints. *Proc.* Rub the senna and corianders in a mortar, and separate by sifting ℥x of the mixed powders. Boil the figs and liquorice in the water, until reduced to one half; then press and strain the liquor. Evaporate the strained liquor until only 24 fluid ounces remain, then add the sugar, and when dissolved, mix in the pulps, and lastly the powder.

Use, Dose, &c. Confection of senna is a gentle and pleasant purgative, and well adapted for persons suffering from piles, and as a laxative during pregnancy. The dose is ¼ to ½ oz. taken at bedtime or early in the morning.

Remarks. Perhaps there is no one pharmacopœial preparation which it is more difficult to obtain of good quality than the above. The absolute cost of an article prepared according to the directions of the College, will be somewhere about 1s. 9*d.* per lb.; but there are many wholesale drug houses vending confection of senna, which they warrant as genuine, at from 9*d.* to 1*s.* a pound. Dr. Paris (in his Pharmacologia) very truly remarks, that "the directions of the Pharmacopœia are very rarely followed." I understand that considerable quantities are manufactured, into which unsound and spoiled apples enter as a principal ingredient. The following forms are, to my knowledge, employed by some members of the trade.

II. Powdered senna, pulp of tamarinds, cassia, and prunes, of each, 1½ lb.; powdered corianders ¾ lb.; Spanish juice ½ lb.; simple sirup 12 lbs.

III. As the above, omitting the cassia pulp, and adding 2 lbs. more tamarind pulp.

Both these articles are labelled P. L., and sent out as genuine, and that when no competition as to price exists. The cheaper article is made as follows:

IV. Common prunes and tamarinds, of each, 16 lbs.; treacle ¾ cwt.; species (a compound of senna dust and small senna, mixed with 3 lbs. of coriander seeds, and strengthened with jalap, all ground to a fine powder) 18¾ lbs. To this is frequently added ¼ cwt. of rotten or inferior apples, which are pulped with the prunes and tamarinds. This article is not unfrequently labelled "CONF. SENNÆ VER." by the conscientious tradesman.

CONFECTION OF SULPHUR, (COMPOUND.) *Prep.* (St. B. H.) Precipitated sulphur ℥ss; cream of tartar ʒj; honey ℥j; mix As a laxative in piles, &c. *Dose.* ℥ss.

CONFECTION OF STEEL. *Syn.* CONFECTION OF CARBONATE OF IRON. *Prep.* Confection of orange-peel and sesquioxide of iron, (P. L.,) of each, 4 oz.; powdered white sugar 6 oz.; simple sirup 2 oz.; mix. Aromatic and tonic. *Dose.* A teaspoonful to ½ oz. twice or thrice daily.

CONGELATION, (from *congelo*, to freeze.) IN CHEMISTRY. The conversion of a liquid into a solid state, by the action of cold.

The production of an extreme degree of cold is often of the utmost importance in chemical operations, and an easy method of doing so is consequently a desideratum. The means hitherto adopted for this purpose have either depended upon the sudden liquefaction of solids, or the abstraction of heat by rapid evaporation. The loss of sensible heat, by the first method, is the basis of the various processes of producing cold by what are commonly called freezing mixtures, all of which act upon the principle of liquefying solid substances without supplying heat. The caloric of liquidity being in these cases derived from that previously existing in the solid itself in a sensible state, the temperature must necessarily fall. The degree of cold produced, depends upon the quantity of heat which is thus diffused through a larger mass, or which, as it were, disappears, and this is dependent on the quantity of solid matter liquefied, and the rapidity of the liquefaction. Saline compounds are the substances most frequently employed, and those which have the greatest affinity for water, and thus liquefy the most rapidly, produce the greatest degree of cold. Thus it is, that chloride of calcium and nitrate of ammonia, when dry and in fine powder, if suddenly mixed with water, produce extreme cold. The latter, suddenly mixed with an equal weight of water at 50°, will sink the thermometer to +4°, or 28° below the freezing point. The most common and convenient freezing mixture, when snow can be procured, is formed by mixing 2 parts of that substance with 1 part of sea-salt. This will sink the thermometer to —5°, or 37° below the freezing point of water. Equal parts of these substances produce a degree of cold marked by the zero of Fahrenheit's thermometer, and is the standard taken for graduating that instrument. Mr. Walker, a gentleman who fully investigated this subject, recommends the following proportions for the production of extreme cold.

PEAU. BEZETTA CŒRULEA. *Prep.* I. Color pieces of clean linen with auvergne or ground archel, (lichen parellus.)

II. Dip pieces of clean linen into the juice of mulberries, blood-red grapes, lees of red wine, &c.

Use. To color jellies and confectionary, and the rind of cheeses.

CLARIFICATION. This word (from *clarus*, clear, and *facio*, I make) means, properly, any process of freeing a fluid from heterogeneous matter, and thus includes filtration. In its commoner sense, however, it is applied to the process of clearing liquids by the addition of some substance that either inviscates the feculous matter, and subsides with it to the bottom, or, that induces such a change in its nature or bulk, that it subsides by its own density, in each case leaving the liquor transparent. Albanum, gelatin, acids, certain salts, blood, lime, plaster of Paris, alum, heat, alcohol, &c., serve in many cases for this purpose. The first is used under the form of white of egg, for the clarification of sirups, as it combines with the liquid when cold, but on the application of heat, rapidly coagulates and rises to the surface, carrying the impurities with it, forming a scum which is easily removed with a skimmer. It is also much used for fining wines and liqueurs, particularly the red wines and more limpid cordials. Gelatin, under the form of isinglass, dissolved in water, or weak vinegar, is used to fine white wines, beer, cider, and similar liquors, that contain a sufficient quantity of either spirit or astringency (tannin) to induce its precipitation. Sulphuric acid is frequently added to weak liquors for a similar purpose, either alone, or after the addition of white of egg, or gelatin, both of which it rapidly throws down in an insoluble form. A pernicious practice exists among some unprincipled parties, of using certain salts of lead and potash to clear their liquors, especially those that are expected to sparkle in the glass, as cordial, gin, &c. For this purpose, a little sugar of lead, dissolved in water, is first mixed up with the fluid, and afterwards about half its weight of sulphate of potash, also dissolved in water, is added, and the liquor is again roused up. By standing, the sulphate of lead, formed by this mixture, subsides, and leaves the liquor clear. Blood is used in the same way as isinglass or white of eggs, for fining red wines, beer, and porter. Lime, alum, alcohol, and heat, act by curdling or coagulating the feculencies, and thus, by increasing their density, induce their subsidence. Plaster of Paris acts partly like the above, and partly like albumine, or gelatin, by enveloping and forcing down the suspended matter. Sand is often sifted over liquors for the simple purpose of acting by its gravity, but appears to be quite useless. The juices of plants are clarified by heat, which coagulates the albumine they contain. Marl, or clay, is frequently used to clear cider and perry. A strip of isinglass is generally employed to clarify coffee. (See WINES, BREWING, CORDIAL, COFFEE, INFUSION.)

CLEANING. The best way to clean a house is to *keep it clean* by a daily attention to small things, and not allow it to get into such a state of dirtiness and disorder as to require great and periodical cleanings. Some mistresses, and also some servants, seem to have an idea that a house should undergo "regular cleanings," or great washing and scrubbing matches once every three or six months, on which occasions the house is turned almost inside out, and made most uncomfortable. All this is bad economy, and indicates general slovenliness of habits. (Chambers.)

CLEAR-STARCHING. This is practised as follows: "Rinse the articles in three waters, dry them, and dip them in a thick starch, previously strained through muslin; squeeze them, shake them gently, and again hang them up to dry; and when dry, dip them twice or thrice in clear water, squeeze them, spread them on a linen cloth, roll them up in it, and let them lie an hour before ironing them. Some persons put sugar into the starch to prevent it sticking while ironing, and others stir the starch with a candle to effect the same end; we object to these practices as injurious to the article starched, or as very nauseous. The best plan to prevent sticking is to make the starch well, and to have the irons quite clean and highly polished."

CLOTH, CLEANING AND SCOURING OF. The common method of cleaning cloth is by beating and brushing, unless when very dirty, when it undergoes the operation of scouring. This is best done on the small scale, as for articles of wearing apparel, &c., by dissolving a little curd soap in water, and, after mixing it with a little ox-gall, to touch over all the spots of grease, dirt, &c., with it, and to rub them well with a stiff brush until they are removed, after which the article may be well rubbed all over with a brush or sponge dipped into some warm water, to which the previous mixture and a little more ox-gall has been added. When this has been properly done, it only remains to thoroughly rinse the article in clean water until the latter passes off uncolored, when it must be hung up to dry. For dark-colored cloths the common practice is to add some fuller's earth to the mixture of soap and gall. When *nearly* dry, the nap should be laid right, and the article carefully pressed, after which a brush, moistened with a drop or two of olive oil, should be several times passed over it, which will give it a superior finish. Cloth may also be cleaned in the dry way as follows:—First, remove the spots as above, and, when the parts have dried, strew clean damp sand over it, and beat it in with a brush, after which brush the article with a hard brush, when the sand will readily come out, and bring the dirt with it. *Black cloth* which is very rusty, should receive a coat of reviver after drying, and be hung up until the next day, when it may be pressed and finished off as before. *Scarlet cloth* requires considerable caution. After being thoroughly rinsed, it should be repeatedly passed through cold spring water, to which a tablespoonful or two of solution of tin has been added. If much faded, it should be dipped in a scarlet dye-bath. *Buff cloth* is generally cleaned by covering it with a paste made with pipe-clay and water, which, when dry, is rubbed and brushed off.

Fruit spots and similar stains may frequently be removed by holding the part over a common brimstone match, lighted, or by water acidulated with a little salt of lemons, oxalic or muriatic acid; but care must be taken not to apply this liquid to colors that it will injure.

The stains of acids may be removed by washing the part with a little spirits of hartshorn or

liquid ammonia; *those of alkalis*, by water acidulated with lemon juice or tartaric acid.

Grease spots may generally be taken out by means of a little soft soap; or, if the color be delicate, or a false dye, a little ox-gall or curd soap will be better. These must be used as above described. *Stains of painters' oils, wax, paints, or varnishes*, will not usually yield to the above plan; in these cases, a simple way is to soak the part in spirits of turpentine, and, when softened, to wash it off with the same fluid. Ether or essential oil of lemons will also quickly remove these spots, but is too expensive for general use.

CLOTH, INCOMBUSTIBLE. This is made of fibres of asbestos by weaving. It will bear a considerable heat without injury. Cotton and linen fabrics prepared with a solution of sal ammoniac, or phosphate of ammonia, may be placed in contact with ignited bodies without danger. They will carbonize, but not inflame. Solutions of alum, sea salt, &c., have been used for the same purpose. It is by a knowledge of this property of ordinary salt, that jugglers are enabled to perform the common trick of burning a thread of cotton while supporting a ring or a key, without the latter falling to the ground. The cotton is reduced to a cinder, but, from the action of the salt, its fibres still retain sufficient tenacity to support a light weight.

CLOTH, RENOVATION OF. The article undergoes the process of scouring before described, and, after being well rinsed and drained, it is put on a board, and the threadbare parts rubbed with a half-worn hatter's card, filled with flocks, or with a teazle or a prickly thistle, until a nap is raised. It is next hung up to dry, the nap laid the right way with a hard brush, and finished as before. When the cloth is much faded, it is usual to give it a "dip," as it is called, or to pass it through a dye-bath, to freshen up the color.

CLOTHES, BRUSHING AND PRESERVATION OF. If very dusty, hang them on a horse or line, and beat them with a cane; then lay them on a clean board or table, and well brush them, first with a stiff brush, to remove the spots of mud and the coarsest of the dirt, and next with a softer one, to remove the dust and to lay the nap properly. If clothes be wet and spotted with dirt, dry them before brushing, and then rub out the spots with the hands. The hard brush should be used as little as possible, and then with a light hand, as it will, if roughly and constantly employed, soon render the cloth threadbare. Should there be spots of tallow-grease on the clothes, take it off with the nail, or, if that cannot be done, have a hot iron with some thick brown paper, lay the paper on the part where the grease is, then put the iron upon the spot; if the grease comes through the paper, put on another piece, till it ceases to soil it.

After the clothes are brushed, they should be hung up in a clean place, free from dust, if wanted for immediate use; but if intended to remain unused for some time, they should be placed away on the shelves of the clothes' closet or wardrobe. The latter should always be in the driest situation possible, as if the clothes be exposed to the least damp, they not only acquire an unpleasant smell, but gradually become rotten.

CLOVES. The flower buds of the eugenia caryophyllata, dried and smoked. It is a common practice to adulterate this spice in the same manner as cinchona bark. Cloves from which the oil has been distilled are dried and rubbed between the hands, previously moistened with a little sweet oil, to brighten their color, after which they are mixed up with fresh spice for sale.

COACH ACCIDENTS. "Should the horses run off, in defiance of all restraint, while you are in a coach, sit perfectly still, and in anticipation of the possible overturn, keep your legs and arms from straggling. Sit easily and compactly, so that, when upset, you will gently roll over in the direction you are thrown. We have seen ladies in these circumstances scream wildly, and throw their arms out of the windows, thus exposing themselves to the chance of broken limbs. If run away with in a gig, either sit still collectedly, or drop out at the back, so as to fall on your hands. Never jump from a rapidly-moving vehicle, unless (supposing it impossible to slip down behind) you see a precipice in front, in which case any risk of personal damage is preferable to remaining still. The Duke of Orleans lost his life by neglecting these simple precautions."

COAK. *Syn.* COKE. CHARRED COAL. MINERAL CHARCOAL. Carbonized coal. The principle of its manufacture is similar to that of charcoal. There are three varieties of coak, viz.

I. (*Kiln-made coak. Stifled coak.*) Made by burning the coal in a pile, kiln, or stove. It has a dull black color, and produces an intense heat when used as fuel. The coal is frequently burnt in a series of shallow stoves, with as little access of air as will support the combustion, and the smoke conducted through proper horizontal tunnels to a capacious brick chamber, 100 yards or more in length, kept as cool as possible by a stream of water passing over its roof, or by a shallow pond resting on it. Here the bituminous vapors are condensed in the form of tar, along with a considerable quantity of crude ammoniacal salt. Common coal yields about 3§ of tar when treated in this way, but some strong bituminous coal will give $\frac{1}{7}$ or $\frac{1}{8}$ of its weight. This tar, when inspissated, gives 75§ of pitch, and 20 to 24§ of a crude species of naphtha, that is excellent for out-door painting. The ammonia is made into sal ammoniac. The *screenings*, or dust-coal, separated from the better kinds of bituminous coal, is the sort commonly used for making coak in ovens.

II. (*Gas coak. Distilled coak.*) The cinder left in the retorts after the gas has been distilled off. Its color is gray, and it only produces a weak heat in burning, not sufficient to smelt iron.

III. (*Slate coak. Carbon mineral.*) From bituminous slate, burned in covered iron pots, in a similar way to that adopted for making bone-black. Also burnt in piles. It is black and friable. Used to clarify liquids, but vastly inferior to bone-black, and does not abstract the lime from sirups.

COBALT. *Syn.* REGULUS OF COBALT. A metal discovered by Brandt, in 1733. It is found in ores, associated with arsenic and other metals, and is constantly present in meteoric iron.

Prep. Dissolve oxide of cobalt in muriatic acid, and pass sulphureted hydrogen gas through the solution, until all the arsenic is thrown down; filter and boil with a little nitric acid, then add an ex-

cess of carbonate of potassa, and digest the precipitate in a solution of oxalic acid to remove any oxide of iron; wash and dry the residuum, which is the pure oxalate, and expose it to heat, either in a retort or crucible, from which the air is excluded, when *pure metallic cobalt* will be obtained.

II. Mix equal parts of oxide of cobalt and soft soap, and expose them to a violent heat in a covered crucible.

III. Roast Cornish cobalt ore, then powder it, and smelt it with twice its weight of soft soap.

Remarks. Cobalt is seldom employed in the metallic state, from the great difficulty of reducing its ores, but its oxide is largely used in the arts. It has been said to form three compounds with oxygen, but only one—the black or peroxide—is employed. It forms salts with the acids, which are interesting from the remarkable changes of color which they exhibit. The *sulphate* is formed by boiling sulphuric acid on the metal, or by dissolving the oxide in the acid. It forms reddish crystals, soluble in 24 parts of water. The *nitrate*, made in a similar way, forms deliquescent crystals. The *muriate* may be made by dissolving the oxide in muriatic acid; the neutral solution is blue when concentrated, and red when diluted; the addition of a little acid turns it green. Dissolved in water, it forms a *sympathetic ink*, the traces of which become blue when heated, but if the salt be contaminated with iron, they become green. (Klaproth.) The addition of a little nitrate of copper to the above solution, forms a sympathetic ink, which by heat gives a rich greenish-yellow color. (Ure.) The addition of a very little common salt makes the traces disappear with greater rapidity, on the withdrawal of the heat. The *acetate* forms an ink which turns blue when heated. The *oxalate* and *phosphate* may be formed by digesting the oxide in a solution of the acid, or by double decomposition. The latter salt is an insoluble purple powder, which, when heated along with 8 times its weight of gelatinous alumina, produces a blue pigment, almost equal in beauty to ultramarine. With sulphur cobalt unites, forming a sulphuret, and with phosphorus a phosphuret.

Char. and Tests. The neutral salts of cobalt form red solutions, turning green on the addition of an excess of the acids, and giving a blue-colored precipitate with the alkalis, unless arsenic be present, when the color will be brown. Their solutions are unaffected by sulphureted hydrogen, but hydro-sulphuret of ammonia throws down a black powder, soluble in an excess of the precipitant. If the solution contain arsenic, a yellow powder is first precipitated, after which the filtered fluid will remain unaffected by sulphureted hydrogen gas. Tincture of galls gives a yellowish-white precipitate, and the solution of oxalic acid a red one.

COBALT, OXIDE OF. *Syn.* Black Oxide of Cobalt. Cobalt Black. *Prep.* To a solution of muriate of cobalt, add another of carbonate of potassa as long as it produces a precipitate; filter, wash, and dry.

II. Boil powdered bright-white cobalt ore (from Cornwall) in nitric acid; dilute with a large quantity of water, and add a solution of carbonate of potassa, very gradually, until the clear liquor, after the impurities have settled, becomes of a rose color: then add the potash water as long as a precipitate falls; wash and dry.

Use. To make blue colors for painters, enamellers, and potters. In medicine it has occasionally been used as a remedy for rheumatism.

COCCULUS INDICUS. The fruit of a shrub (the menispermum cocculus) which abounds on the sandy shores of Malabar, and other parts of the East Indies. It contains about 2§ of picrotoxin, a peculiar vegetable principle, possessing very poisonous properties. It also contains menispermine and paramenispermine. (Pelletier and Couerbe.) A small portion of this dangerous drug is used by poachers, and a still smaller quantity to destroy vermin, the remaining, and by far the greater part, being used to adulterate beer and wine. It forms a profitable article of trade to the wholesale druggist, who is enabled to sell it at a high price to brewers, from its being a contraband article. The use of cocculus indicus in brewing is no secret, as several writers have openly recommended its use. One of these conscientious gentlemen states, that "it is impossible with pure malt and hops alone, to produce a strong-bodied porter;" he therefore recommends the use of "cocculus indicus, grains of Paradise, and nux vomica." (Childe, on Brewing.) Another author, with the most unblushing effrontery, actually gives full directions for its use. He orders 3 lbs. of cocculus to be used for every 10 quarters of malt, and adds, "it gives an inebriating quality, which passes for strength of liquor; it prevents second fermentation in bottled beer, and consequently, the bursting of the bottles in warm climates." (Morrice's Treatise on Brewing.) It is really disgusting to find that men can so degrade themselves, as thus publicly to recommend a wholesale system of slow poisoning. The conscientious brewer, who understands the art which he professes, finds no difficulty in producing "a strong-bodied porter" from malt and hops alone. It is only persons whose cupidity induces them to reduce the quantity of malt and hops required for the production of good liquor, that encounter any difficulty in so doing. There is a penalty of 200*l.* upon the brewer for purchasing or having in his possession any ingredient for the adulteration of beer, and there is a penalty of 500*l.* upon the seller of such ingredients. Yet, in defiance of these heavy fines, the trade in these articles is unabated, though carried on in a clandestine manner. The general way this is managed, is to pack the drug in common soda barrels, and to place 3 or 4 inches of small crystals of Scotch soda at the bottom and top of the cask. In this way the package readily passes off as a cask of common soda, and even should it be opened, the alkali would first present itself to view, and thus satisfy the examiner. Another way commonly adopted, is to form it into an extract, known by the name of B. E., or *black extract*, which is *ostensibly* prepared for tanners, but its real destination is the beer cask. The store of a certain druggist, which came under my examination some short time since, contained an immense number of bags of this article; in fact, it formed at least one fourth of the entire stock.

COCHENILLIN. *Syn.* Cochineal Red. Carminium. Carminia. Pure Carmine. The coloring principle of cochineal. The carmine of commerce consists of cochenillin, combined with a

tile animal matter and an acid, from which it may be nearly purified by solution in liquid ammonia, and precipitations by acetic acid, mixed with alcohol. Cochenillin may also be prepared by evaporating a watery infusion of cochineal to the consistence of sirup, dissolving this in proof spirit, filtering, again evaporating, and dissolving the residuum in liquid ammonia as before. It is turned orange by acids, and violet by alkalis. It has been obtained under the form of reddish-purple crystalline grains.

COCKLE POWDER. Cockles pulped through a sieve, made into a paste with flour, and a little salt, and then rolled out into thin pieces and dried. It is next reduced to powder, sifted, and packed in well-corked bottles. *Use.* To make sauce, (about ½ oz. to ½ pint.)

COCOA. I. The roasted husks of the cacao, or chocolate bean, reduced to powder by grinding.

II. The cake left after expressing the oil from the beans.

COCOA, PATENT. The cacao nut roasted and ground. (including the husks.)

COCOA, FLAKED. Ground cocoa strongly compressed, and flaked with a sharp knife or machine.

COCOA, SOLUBLE. Cocoa ground to a very fine powder, and mixed with sugar. It is thus rendered miscible with boiling water.

Remarks. Cocoa forms a very wholesome beverage, especially for breakfast. Much of the cheap stuff sold under this name is very inferior, being made with damaged nuts that have been pressed for the oil, mixed with potato flour, mutton suet, &c. Trash of this kind is frequently ticketed in the shop windows of London at 6*d.* to 8*d.* a pound. (See CHOCOLATE.) The nut of the palma cocos is commonly confounded with that of the theobroma cacao. The latter is the small chocolate bean, while the former is the large nut, filled with a refreshing milky juice.

COD. This excellent fish is in season from the beginning of October to the end of April. It should be chosen by the redness of the gills, freshness of the eyes, and the whiteness and firmness of the flesh. The best fish are very thick about the neck. It is generally cooked by boiling, but is sometimes baked, or cut into slices and broiled or fried. Cod's head and shoulders, with oyster sauce, is a favorite dish. Shrimp and anchovy sauce are also good additions. The flesh of the cod is often split and dried, (dried cod,) or salted. The fish so largely imported from Newfoundland are cod, beheaded, split open, gutted and salted. They are caught by millions on the "Grand Bank." Cod-sounds are pickled in brine and also made into isinglass. The liver is boiled for its oil, and the spawn made into caviare.

CODEIA. *Syn.* CODEINE. An alkaloid discovered by Robiquet associated with morphia.

Prep. Dissolve commercial hydro-chlorate of morphia in water, precipitate with ammonia, evaporate and crystallize. The product is a double salt of morphia and codeine, and when digested with warm liquor of potassa gives up its morphia. It may be further purified by solution in ether, and by the addition of a little water and spontaneous evaporation may be obtained quite pure and in a crystalline state.

Prop. Soluble in alcohol, ether, and water. Its solution in the latter, by slow evaporation, yields large transparent octohedrons. With the acids it forms crystallizable salts. These possess the singular property of producing a general and violent itching of the surface of the body when administered internally. The same symptoms frequently follow the exhibition of opium and muriate of morphia, and are referred to the presence of a salt of codeia. (Gregory.) The commercial muriate frequently contains 3 to 4⅝ of codeia.

Char. and Tests. It is distinguished from *morphia* by not becoming blue on the addition of the sesquichloride of iron, nor turning red with nitric acid, and by not being precipitated by ammonia, when dissolved in muriatic acid and mixed with a large quantity of water. Unlike morphia, it is insoluble in liquor of potassa and is soluble in ether. The salts of codeia may also be known by tincture of galls throwing down a copious precipitate from their solutions, but this does not occur in the salts of morphia. It may be distinguished from meconine by its aqueous solution showing an alkaline reaction with test paper.

COFFEE. The berry of the coffæa Arabica. II. A decoction or infusion prepared therefrom.

Qual. Coffee promotes digestion and exhilarates the spirits, and when strong generally occasions watchfulness, but in some phlegmatic constitutions induces sleep. Drunk in moderation, especially if combined with sugar and milk, it is perhaps the most wholesome beverage known. The various qualities that have been ascribed to it by some persons, such as dispelling or causing flatulency, removing dizziness of the head, attenuating the blood, causing biliousness, &c., appear to be wholly imaginary. In a medical point of view it has been regarded as diuretic, sedative, and a corrector of opium. It should be given as medicine in a strong infusion, and is best cold. In spasmodic asthma it has been particularly serviceable; and it has been recommended in gangrene of the extremities arising from hard drinking. (See CAFFEIN.)

Pur. The most common adulteration of ground coffee is chicory, which is added not only to cheapen the article, but to improve the flavor of damaged or inferior berries. This adulteration may be readily detected by shaking a spoonful of the suspected coffee with a wine-glassful of water, when, if it be pure, it will swim and scarcely color the liquid, but if chicory be present, it will sink to the bottom, and the water will be tinged of a deep red. *Roasted corn* is another common adulteration. This may be detected by the cold decoction striking a blue color with tincture of iodine.

COFFEE CREAM. *Prep.* Add a teacupful of very clear strong coffee to 1 pint each of clarified calf's feet jelly and good cream; sweeten with lump sugar, give it one boil up, and pour it into shapes or glasses, when nearly cool. The calf's feet jelly should be thick enough to render the whole lightly solid but not stiff.

COFFEE DROPS. *Prep.* Make an infusion with 1 oz. of coffee, clarify it, and moisten 1 lb. of sugar therewith, in the way directed for confectionary drops.

COFFEE, ESSENCE OF. A concentrated infusion of coffee prepared by percolation, to which

VI. Fish may be preserved in a living state for 14 days or longer without water, by stopping their mouths with crumb of bread steeped in brandy, pouring a little brandy into them, and then placing them in straw in a moderately cool situation. (Prechtl. Encycl. Techn.)

VII. Immersion of the *cleaned* fish in water holding in solution $\frac{1}{300}$ or $\frac{1}{1400}$ part of creosote, and then drying them.

VII. Fish may be preserved in a dry state, and perfectly fresh, by means of sugar alone. Fresh fish may be thus kept for some days, so as to be as good when boiled as if just caught. If dried and kept free from mouldiness, there seems no limit to their preservation; and they are much better in this way than when salted. The sugar gives no disagreeable taste. This process is particularly valuable in making what is called *kippered salmon;* and the fish preserved in this manner are far superior in quality and flavor to those which are salted or smoked. A few tablespoonfuls of brown sugar are sufficient for a salmon of five or six pounds weight; and if salt be desired, a teaspoonful may be added. Saltpetre may be used instead, in the same proportion, if it be wished to make the kipper hard. (See ANIMAL SUBSTANCES USED AS FOOD.)

FIXATEUR. *Syn.* BANDOLINE. *Prep.* Soak Iceland moss in cold water for an hour or two, drain and dissolve in boiling water.

Remarks. A solution of gum arabic in water is also commonly called by the same name. It is used by ladies to make their hair curl firmly, and remain in any required position. It is applied by moistening the fingers, and passing the hair through them. Beer has a similar effect.

FLANNEL. It has been shown by the experiments of Count Rumford that the conducting power of the different materials employed for clothing varies considerably. A thermometer, surrounded with cotton-wool, and heated by immersion in boiling water, took 1046 seconds to lose 135°, when plunged into a bath of melting ice; but, under the same circumstances, when sheeps' wool was employed, 1118 seconds elapsed before a like sinking of the thermometer took place, (Phil. Trans. 1792;) thus showing the greater conducting power of the former, and consequently the superiority of the latter substance for the manufacture of warm clothing. But the chief advantage of wool as an article for under-clothing depends less upon its actual power of conducting heat than its peculiar texture. Flannel acts as a gentle stimulus on the skin, and exercises the most beneficial action, by keeping the pores clean, and in a state most favorable to perspiration. It has also the advantage of absorbing the perspiration as soon as emitted, and allowing its watery portion to pass off into the atmosphere almost as soon as formed, but this is not the case with cotton and linen fabrics. The different effects of flannel and linen are particularly perceptible during brisk exercise. When the body is covered with the former, though perspiration be necessarily increased, the perspired matter freely passes off through the flannel, and the skin remains dry and warm. If the same exercise be taken in linen shirts, perspiration, as in the former case, is indeed also increased, but the perspired matter, instead of being dispersed into the atmosphere, remains upon the linen, and not only clogs the pores of the skin, but gives a disagreeable sensation. From this property of flannel, persons who wear it next the skin seldom catch cold from changes of temperature, even though perspiring profusely; but in similar cases, when linen or calico shirts are worn, chilliness immediately comes on, followed by "*sniffling, sneezing*, and *cough*," and all the other symptoms of severe catarrh.

The common objections raised against the use of flannel are founded on vulgar prejudices, arising from ignorance, obstinacy, or bravado, and are undeserving of the notice of sensible people. In a fickle and moist climate like that of England, every person should wear a robe of flannel next the skin, or at all events a waistcoat of flannel reaching below the loins; and this should not be discarded as soon as the cold weather has passed, but its use should be continued all the year round; for in reality, flannel is, if possible, even more required in summer than in winter, because persons perspire more freely in hot than in cold weather, and are consequently more susceptible of cold, while at that period of the year their clothing is less capable of protecting them from the effects of sudden changes of temperature, and draughts of cold air, moisture, &c. Females, children, persons of delicate constitutions, and all others, who, from their habits of body or life, perspire freely, or are much exposed, should wear flannel.

In washing flannels, it is said they should be always put into scalding hot water, by which method their color will be preserved, and they will be prevented from shrinking.

FLASH. *Prep.* Burnt-sugar coloring 1 gall. fluid extract of capsicum, or essence of cayenne ½ pint, or enough to give a strong fiery taste.

Use. It is employed to color spirits, and to give them a false strength. It is made by the brewers' druggists, and vended under the name of "*isinglass and burnt sugar.*"

FLATULENCY. (From *flatus*, a blast.) A morbid collection of gas in the stomach and bowels. The most common cause of flatulency is indigestion. When the natural fluids of the stomach are secreted in a healthy state, they exercise an antiseptic and digestive action on the food, by which it is speedily reduced to a magma that is little liable to spontaneous change while in the body; but when the reverse is the case, fermentation rapidly commences, and the stomach and associated viscera become distended with gas, giving rise to frequent eructation and crepitation. The quantity of gas thus accumulated is often enormous. It is asserted that an ordinary apple during fermentation yields about 600 times its bulk of gas, and many vegetables much more. (Dr. Hales.) It is therefore, not at all surprising that so much inconvenience should be felt from flatulency.

Treat. The treatment of flatulency consists mainly in the selection of proper articles of food. Oleraceous vegetables, peas, beans, and indigestible fruits, should be especially avoided, as well as the use of large quantities of washy liquids. The diet should consist principally of animal food, well cooked, with a sufficient quantity of good potatoes and wheaten bread, moderately seasoned with spice, and the most suitable beverages are toast and w

a very low temperature, (in vacuo if possible,) until the mixture acquires the consistence of a syrup, paste, or candy. (The latter may be powdered.)

COFFEE, SUBSTITUTES FOR. These are numerous, but the principal are the following:

I. (*Rye coffee. Dillenius's ditto. Hunt's breakfast-powder.*) Rye, roasted along with a little butter, and ground to powder. A good substitute.

II. (*German coffee. Succory ditto. Chicory ditto.*) From succory, as above. *Used* either for or mixed with foreign coffee. The most common adulteration of the latter.

III. (*Rice coffee.*) From rice, as above. A good substitute.

IV. (*Currant coffee.*) From the seeds washed out of the cake left in making currant wine.

V. (*Gooseberry coffee.*) From gooseberry seeds, as the last.

VI. (*Holly coffee.*) From the berries.

VII. (*Egyptian coffee.*) From chickpeas.

VIII. (*Rosetta coffee.*) From fenugreek seeds moistened with lemon juice.

IX. (*Corsican coffee.*) From the seeds of the knee-holly.

X. (*Sassafras coffee.*) From the fruit or nut of the sassafras tree, or from the wood cut into chips. Very wholesome. Much recommended in skin diseases, &c.

XI. (*Raspings.*) The raspings of the crust of loaves, procured at the baker's. Equal to rye coffee.

XII. (*Beech-mast coffee.*) From beech-mast or nuts. Very wholesome.

XIII. (*Acorn coffee.*) From acorns, deprived of their shells, husked, dried, and roasted. A good substitute.

XIV. (*Beet-root coffee.*) From the yellow beet-root, sliced, dried in a kiln or oven, and ground with a little foreign coffee. A good substitute.

XV. (*Bean coffee.*) Horse-beans roasted along with a little honey or sugar. When removed from the fire, a small quantity of cassia-buds is frequently added, and the whole is stirred until cold. Said to be a good substitute.

XVI. (*Almond coffee.*) Rye or wheat roasted along with a few almonds. A very small quantity of cassia-buds improves it. A good substitute.

COINS, IMPRESSIONS FROM. A very easy and elegant way of taking the impressions of medals and coins, not generally known, is as follows: Melt a little isinglass glue with brandy, and pour it thinly over the medal, so as to cover its whole surface; let it remain on for a day or two, till it has thoroughly dried and hardened, and then take it off, when it will be fine, clear, and as hard as a piece of Muscovy glass, and will have a very elegant impression of the coin. It will also resist the effects of damp air, which occasions all other kinds of glue to soften and bend if not prepared in this way. (Shaw.) If the wrong side of the isinglass be breathed on, and gold-leaf applied, it will adhere, and be seen on the other side, producing a very pleasing effect. Isinglass glue, made with water alone, will do *nearly* as well as if brandy be used.

Remarks. Medals may also be copied by surrounding them with a hoop of paper, and pouring on them plaster of Paris (mixed with water to the consistence of cream) to the depth of about ½ an inch. Melted wax, stearine, fusible metal, or any similar material, may be used in the same way. If it be desired to copy the metal in copper, a mould should be first formed in the above manner, and the metal deposited on its surface by the agency of electricity. (See ELECTROTYPE.)

COLCHICINE. *Syn.* COLCHICINA. COLCHIA. A peculiar principle discovered by Gieger and Hesse in the seeds of the colchicum autumnale, or common meadow saffron. It also exists in the cormi or bulbs.

Prep. Macerate the crushed seeds in boiling alcohol, add hydrate of magnesia to throw down the alkaloid, digest the precipitate in boiling alcohol, and filter. By cautious evaporation colchicine will be deposited. It may be purified by re-solution.

Prop., &c. Odorless; tastes bitter; forms salts with the acids. It is very poisonous. One-tenth of a grain, dissolved in spirit, killed a cat in 12 hours. It differs from veratrine in being soluble in water, crystalline, and the non-production of sneezing when applied to the nose. Strong oil of vitriol turns this alkaloid of a yellowish brown; nitric acid of a deep violet, passing into indigo blue, green, and yellow.

COLCHICUM, POWDER OF. I. (*Collier.*) Seeds of colchicum 2 grs.; rhubarb 6 grs.; magnesia 10 grs.; mix for 1 powder, to be taken every six hours in acute rheumatism, inflammatory gout, &c., washing it down with a glass of Seltzer water, during high febrile action only.

II. (*Collier.*) Seeds of colchicum 3 grs.; muriate of ammonia 5 grs.; for 1 powder. For checking a paroxysm of gout, but its use requires caution. "After all that has been said respecting colchicum in gout, and admitting that it rarely fails to allay pain and check a paroxysm, I would record my opinion that he who would wish to arrive at a good old age, should eschew it as an ordinary remedy, and consider that he is drawing on his constitution for a temporary relief, with a certainty of becoming prematurely bankrupt in his vital energies."

COINDET'S PILLS. *Prep.* Protiodide of mercury 1 gr.; extract of liquorice 20 grs.; mix, and divide into 8 pills. *Dose.* 2 to 4 twice or thrice daily, as an alterative in scrofulous tumors, ulcers, &c.

COLD. When the body of an animal is immersed in an atmosphere at a temperature below the healthy standard, a sensation of coldness is experienced, produced by the passage of the caloric or heat of the body into the colder medium. If this withdrawal of caloric exceed the quantity produced by the vital system, the temperature of the body decreases, until it sinks below the point at which the functions of life can be performed. This declination is gradual; the extreme sensation of coldness changes into a disinclination for voluntary motion; next comes on drowsiness, followed by numbness and insensibility. In this state, if the sufferer be not rescued, and remedial measures had recourse to, death must rapidly follow.

Prevention of the effects of excessive cold.—The extremities of the body first suffer from the action of cold, owing to the circulation of the blood being less vigorous in those parts; they should,

d. Evaporate or distil off the spirit from the solution and washings as above; the residuum is sugar.

e. Dry the substances educed by the preceding operations by a *gentle* heat, and weigh them. The weight of the albumen may be taken with that of the gluten, as it possesses about the same nutritive value, and also because it has been asserted by some persons that the former substance is in reality gluten, and not albumen. By dividing the given weights by 10, the per centage value of the sample will be obtained. The pieces of filtering paper employed should be dried and weighed before using them; and the same degree of heat should be employed for this purpose, as that to which they will be afterwards exposed in the drying of the substances resulting from the operation.

Remarks. This method of ascertaining the actual value of any sample of flour as an article of food, though not strictly accurate, approximates sufficiently to the truth for all practical purposes, and is well adapted to the wants of the baker and large purchaser. In many cases it will only be necessary to perform the first part of the process, *a*, which will give the amount of the most important constituent of the flour; the rest being of minor consequence.

According to Vauquelin, French wheat flour contains about 10% of water, 11% of gluten, 71% of starch, 5% of sugar, and 3% of gum; and the water of the dough amounts to 50·3%.

FLOUR, BAKED. *Syn.* Farina tosta. F. Tritici Tosta. Astringent; used to make food for infants troubled with diarrhœa.

FLOWERS. *Syn.* Flores, (*Lat.*) Fleurs, (*Fr.*) Blumen, (*Ger.*) These beautiful and fragrant ornaments of our gardens, our sitting-rooms, and our chambers, are too well known to require description; but some remarks on their preservation, &c., may not be out of place here.

Flowers may be preserved in a fresh state for a considerable time, by keeping them in a moist atmosphere. When growing on the parent stem, the large amount of evaporation from the surface of their leaves, is compensated for by an equivalent proportion of moisture supplied by the roots; but when they are plucked, the evaporation from the surface continues, while the supply of moisture is cut off. Hence they fade, and that with a degree of rapidity exactly proportionate to the dryness of the air that surrounds them. It is on this account that recently-plucked flowers fade more rapidly indoors than in the open garden; for the air of a sitting-room is considerably *drier* and *warmer* than the external atmosphere. This is perfectly natural; for with diminished sources of nourishment, they are exposed to an augmented perspiration, and the water which forms the larger portion of their bodies is lost. In fact, they fade from the volatilization of one of their component parts, which is an essential constituent of every *living* flower. The flowers of plants also feed on the viewless oxygen of the air, and form carbonic acid with great rapidity. Thus those of the *passiflora serratifolia* consume of oxygen in this way 18½ times their bulk in 24 hours, when sheltered from the direct rays of the sun, at a temperature between 18° and 25° C.; the male flowers of the cucumber, 12 times their bulk; the female only 3½; the single red gilliflower (*cheiranthus incanus*) 11; the single tuberose 9; and the *typha latifolia* 9·8. (T. de Saussure, Ann. de Chim. xxi. 279.) To supply in part the loss of moisture by evaporation, has arisen the universal practice of placing them in water; but the mutilated stems possess a far inferior power of sucking up fluids to that of the roots, and though their decay may thus be slightly impeded, yet, as the balance of *gain* on the one hand by the roots, and *loss* on the other hand by evaporation from their whole surface, cannot be maintained, they fade as a natural consequence. To preserve them, or at least to render their existence less ephemeral, we have therefore only to restore this balance—to surround them with a medium that will rob them of no water; or, in other words, to place them in a moist atmosphere. "It is now eighteen years ago since we first saw, in the drawing-room of a gentleman, in the hot dry weather of the dog-days, flowers preserved day after day in all their freshness by the following simple contrivance:—A flat dish of porcelain had water poured into it. In the water a vase of flowers was set; over the whole a bell-glass was placed with its rim in the water. This was a 'Ward's case' in principle, although different in its construction. The air that surrounded the flowers being confined beneath the bell-glass, was constantly moist with the water that rose into it in the form of vapor. As fast as the water was condensed, it ran down the sides of the bell-glass back into the dish; and if means had been taken to enclose the water on the outside of the bell-glass, so as to prevent its evaporating into the air of the sitting-room, the atmosphere around the flowers would have remained continually damp. The only difference between plants in a 'Ward's case' and flowers in the little apparatus just described is this—that the former is intended for plants to grow in for a considerable space of time, while the latter is merely for their preservation for a few days; and that the air which surrounds the flowers is always charged with the same quantity of vapor, and will not vary with the circumstances, and at the will of him who has the management of it. We recommend those who love to see plenty of fresh flowers in their sitting-rooms in dry weather, to procure it. The experiment can be tried by inverting a tumbler over a rose-bud in a saucer of water." (Gardener's Chronicle.)

Faded flowers may be generally restored by immersing them half-way up their stems in very *hot* water, and allowing them to remain in it until it cools, or they have recovered. They must then be removed, the '*coddled*' portion of the stems cut off, and placed in clean cold water. In this way a great number of faded flowers may be restored, but there are some of the more fugacious kinds on which it proves useless.

To hasten the blowing of flowers the following liquid has been used with great advantage:—Sulphate or nitrate of ammonia 4 oz.; nitrate of potash 2 oz.; sugar 1 oz.; hot water 1 pint; dissolve and keep it in a well-corked bottle. *For use*, put 8 or 10 drops of this liquid into the water of a hyacinth-glass or jar for bulbous-rooted plants, changing the water every 10 or 12 days. For flowering plants in *pots* a few drops must be added to the water employed to moisten them. The preference

water the latter is removed. It may be purified by solution in alcohol, and evaporation.

Prop. A yellowish brown translucent resinous substance, very soluble in alcohol, less so in ether, and only slightly so in water. It is intensely bitter, and acts as a drastic purgative.

COLORING. *Syn.* BREWER'S COLORING, BRANDY DO. SPIRIT DO. ESSENTIA BINA. CARAMEL. *Prep.* Melt brown sugar in an iron vessel over the fire, until it grows black and bitter, stirring it well all the time, then make it into a sirup with water.

Remarks. Some use lime-water to dissolve the burnt sugar. Care must be taken not to overburn it, as a greater quantity is thereby rendered insoluble. The heat should not exceed 430°, nor be less than 400°. The process for nice experiments is best conducted in a bath of melted tin, to which a little bismuth has been added to reduce its melting point to about 435°; a little powdered resin or charcoal, or a little oil being put upon the surface of the metal to prevent oxidizement.

COLORS, COMPOUND. (IN DYEING.) The mixture of BLUE and YELLOW dyes produces *green;* RED and BLUE, *violet, purple, lilacs, &c.;* RED and YELLOW, *orange, cinnamon, &c.;* RED, YELLOW, and BLUE, *olives;* RED and BLUES, or GREEN or BLACK, *browns* of all shades; BLACK mixed with other dyes produces various shades of *brown* and *olive*, and when pale it constitutes *gray*, either by itself or the addition of a faint blue.

COLOMBIUM. A rare metal, discovered by Mr. Hatchet in 1801, in a black mineral belonging to the British Museum. Supposed to have been brought from America, hence the name. (See TANTALUM.)

COLUMBIC ACID. The preceding metal exists in its ores in the form of an acid, united to iron, manganese, or yttria. From these it may be obtained by fusion with 3 or 4 parts of potash, solution in water, and precipitation with an acid. It falls as a white powder or hydrate.

CONCENTRATION. (IN CHEMISTRY.) The volatilization of part of a liquid in order to increase the strength of the remainder. The operation can only be performed on solutions of substances of greater fixity than the menstrua in which they are dissolved. Many of the liquid acids, solutions of the alkalis, &c., are concentrated by distilling *off* their water.

(IN PHARMACY.) The term "concentrated" is very commonly applied to any liquid preparation possessing more than the usual strength. Thus we have "*concentrated*" *infusions, decoctions, liquors, solutions, tinctures,* and *essences,* most of which are made of 8 times the common strength. This is generally effected by using 8 times the usual quantity of the ingredients, with a given portion of the menstruum, and operating by digestion or percolation; the latter being generally adopted when the articles are bulky. When the menstruum is water, a little spirit is added to make the product keep.

CONCRETE. (IN ARCHITECTURE.) A compact mass, composed of pebbles, lime, and sand, employed in the foundations of buildings. The best proportions are 60 parts of coarse pebbles, 25 of rough sand, and 15 of lime.

CONDIMENTS. Substances taken with the food, to improve its flavor, or to render it more wholesome or digestible. The principal condiments are common salt, vinegar, lemon juice, spices, aromatic herbs, oil, butter, sugar, honey, and sauces. Most of these, in moderation, promote the appetite and digestion, but their excessive use tends to injure the stomach, and vitiate the gastric juice.

CONFECTIONS. (IN PHARMACY.) Medicines, usually pulverulent, mixed up to the consistence of a paste with powdered sugar, sirup, or honey. In the "London Pharmacopœia," both conserves and electuaries are included under this head, though there appears to be some little distinction between them. As remedial agents, the officinal confections possess but little value, and are chiefly useful as vehicles for the administration of more active medicines. In making confections, the sugar requires the same attention as for sirups. They should be kept in stone jars, covered with writing paper, and placed in a cool and dry situation. Without this precaution, they are apt to mould on the top. All the dry ingredients employed in making confections should be reduced to a very fine powder, and passed through a sieve not coarser than 80 holes to the inch.

CONFECTION OF ALMONDS. *Prep.* (*Confectio Amygdalæ*, P. L.) Sweet almonds ℥viii; white sugar ℥iv; powdered gum arabic ℥j. Macerate the almonds in *cold* water, then remove the skins, and beat them with the other ingredients until reduced to a smooth confection.

Use. To prepare milk of almonds. A little of this paste or powder, triturated with a sufficient portion of water, and strained through a piece of calico, forms emulsion of almonds.

CONFECTION OF ALKERMES. *Prep.* White sugar 1 lb.; rose-water ¼ pint; clarified juice of alkermes 3 lbs.; oil cinnamon 10 or 12 drops. Mix. It was formerly a common practice to add a little gold-leaf, rubbed small, so as to float about in it; also musk and ambergris.

CONFECTION OF ALUM. *Prep.* (*Conf. Aluminis*, St. B. H.) Alum in fine powder, 80 grs.; conserve of roses, enough to mix. *Use.* As an astringent.

CONFECTION, AROMATIC. *Syn.* SIR WALTER RALEIGH'S CORDIAL. CONFECTIO RALEIGHANA, (P. L. 1720.) DITTO CARDIACA, (P. L. 1745.) DITTO AROMATICA, (P. L. 1788, and since.) *Prep.* I. (P. L.) Nutmegs, cinnamon, and hay saffron, of each ℥ij; cloves ℥j; cardamoms ℥ss; prepared chalk ℥xvj; white sugar lbs. ij. Reduce the whole to a very fine powder, and keep it in a closed vessel. When wanted for use, mix it with water to the consistence of a confection.

Remarks. On the large scale the above form is seldom adhered to. Less saffron is commonly used, cassia is substituted for cinnamon, and, generally, the essential oil for the powder of cloves. Should there be any deficiency of color, this is brought up by a little tincture or infusion of turmeric. When a very smooth and fine powder is desired, it should be passed through a gauze sieve, not coarser than 80 holes to the inch, and precipitated chalk should be employed. The saffron should be dried with as little heat as possible, and care should be taken not to waste any in powdering. The following formula, which is employed by a large whole-

sale druggist in the city, produces an excellent article.

II. Hay saffron, cassia, and turmeric, of each 4 oz.; cardamoms 1 oz.; starch 8 oz.; precipitated chalk 2 lbs.; white sugar 4 lbs.; oil of nutmegs 2 drachms; oil of cloves 3 drachms. Reduce the dry ingredients to fine powder, and pass it through an 80 hole sieve, then add the oils, and after well mixing, pass it through a coarse sieve, (about 40 holes to the inch,) to ensure the whole being perfectly mixed.

The following form produces a powder possessing great depth and brilliancy of color.

III. Hay saffron 4 oz.; turmeric 3 oz.; powdered starch 8 oz.; precipitated chalk 2 lbs.; white sugar 4 lbs.; oils of cloves and cassia, of each 3 drachms; oil of nutmegs 2 drachms; essence of cardamoms 1 oz. *Proc.* Boil the saffron and turmeric in 1 gallon of water, placed in a bright copper pan, for 10 minutes, then, without straining, add the chalk, starch, and sugar; mix well, and continue stirring until the mixture becomes quite stiff, then break it up and dry it until fit for powdering. This must be performed in a water or steam bath. To the powder, passed through a fine sieve, as before, the oils and tincture must be added, and after being well mixed, and passed through a coarse sieve, it should be placed in a jar or bottle, and bunged up close.

Remarks. In the wholesale trade this article is kept under two forms: one in powder, as ordered by the College, and commonly called, for distinction sake, "*pulvis confectionis aromaticæ;*" the other mixed up ready for use. In preparing the latter, it is a common plan to make a strong infusion or decoction of the saffron, and to use it to mix up the other ingredients. Some persons follow the method described in the last formula, mixing up the powder to a proper consistence with water before adding the aromatics. When the price of *precipitated* chalk is an objection to its use, *prepared* chalk may be used instead. This confection is cordial, stimulant, and antacid. *Dose.* 10 to 60 grs.

CONFECTION OF BLACK PEPPER. *Syn.* Ward's Paste. *Prep.* (*Confectio Piperis Nigri*, P. L.) Black pepper and elecampane root, of each lb. j; fennel seed lb. iij; honey and white sugar, of each lb. ij; mix.

Remarks. The common practice is to keep the dry ingredients ready mixed in a bottle, and only to add the honey as wanted. The proportions are 2 parts of the latter to 7 of the mixture. The *dose* is 1 to 2 drachms 2 or 3 times a-day, in piles, fistula, &c. It should be persevered in for 2, 3, or 4 months, (Sir B. Brodie;) and as it is apt to accumulate in the bowels, its use should be accompanied by mild aperients. (Pereira.)

CONFECTIONS OF CASSIA. *Syn.* Electuarium Cassiæ, (P. L. 1788.) *Prep.* (*Confectio Cassiæ*, P. L.) Fresh cassia pulp lb. ss.; manna ℥ij; tamarind pulp ℥j; sirup of roses f℥viij. Bruise the manna and dissolve it in the sirup, then add the pulps and evaporate to a proper consistence.

CONFECTION OF HEMLOCK. (Dr. Osborne.) *Prep.* Fresh leaves of hemlock and moist sugar equal parts; beat them to a confection in a mortar.

CONFECTION OF OPIUM. *Syn.* Philonium Romanum, (P. L. 1720.) Ditto Londinense, (P. L. 1745.) Confectio Opiata, (P. L. 1788.) Ditto Opii, (P. L. 1809, and since.) *Prep.* (P. L.) Powdered opium ʒvj; long pepper ℥j; ginger ℥ij; caraways ℥iij; tragacanth ʒij; all in fine powder; sirup f℥xvj. Mix.

Use and Dose. This confection is intended as a substitute for the *mithridate* and *theriaca* of the old Pharmacopœia. It is stimulant and narcotic, and is given in flatulent colic and diarrhœa unaccompanied by fever. The dose is from 15 to 50 grs.

CONFECTION OF ORANGE PEEL. *Syn.* Conserva flavedinis Corticum Aurantiorum, (P. L. 1720 and 1745.) Ditto Corticis exterioris Aurantii Hispalensis, (P. L. 1788.) Ditto Aurantiorum, (P. L. 1824.) Ditto Aurantii, (P. L. 1809 and 1836.) *Prep.* (P. L.) The external rind of the fresh orange, separated by rasping, lb. j; white sugar lb. iij. Beat the rind in a stone mortar with a wooden pestle, then add the powdered sugar, and beat the mixture until the two are perfectly incorporated.

Remarks. This confection is tonic and stomachic, and is principally used as a vehicle for the exhibition of tonic powders.

CONFECTION OF PEPPERMINT. *Prep.* Green peppermint 4 oz.; powdered white sugar 12 oz.; beat them together as last.

Use. Anti-emetic and flatulent. Given in colic, &c., in the form of a bolus, or made into a mixture.

CONFECTION OF THE DOG ROSE. *Syn.* Confection of Hips. Conserva Fructus Cynosbati, (P. L. 1720 and 1745.) Ditto Cynosbati, (P. L. 1788.) Ditto Rosæ Caninæ, (P. L. 1809, and since.) *Prep.* (P. L.) Pulp of the dog rose lb. j; powdered refined sugar ℥xx; mix by a gentle heat in an earthen vessel.

II. Pulped hips 2 cwt.; fine white sugar 2½ cwt.; incorporate them without applying heat.

Remarks. Both this and the following confection has a brighter color, if made without heat, or touching metallic vessels. On the small scale it is made by beating the ingredients together in a marble mortar, but in large quantities by grinding in a mill. It is slightly laxative, and is principally used for forming pills. It candies by keeping.

CONFECTION OF THE RED ROSE. *Syn.* Conserva Rosarum Rubrarum, (P. L. 1745.) Ditto Rosæ, (P. L. 1788.) Ditto Rosæ Gallicæ, (P. L. 1809 and 1824.) Confectio Rosæ Gallicæ, (P. L. 1836.) *Prep.* (P. L.) Petals of the red rose lb. j; refined sugar lb. iij; beat the petals in a stone mortar, then add the sugar, and again beat until thoroughly incorporated.

Remarks. On the large scale this is prepared like the confection of hips. It is astringent and tonic, and principally used for forming pills. If taken alone, the dose is 1 to 2 drachms.

CONFECTION OF RUE. *Syn.* Electuarium e Boccis Lauri, (P. L. 1720, 1745.) Confectio Rutæ, (P. L. 1809, and since.) *Prep.* (P. L.) Dried rue, caraway, and laurel berries, of each ℥iss; sagapenum (true) ℥ss; black pepper ʒij; honey ℥xvj. Reduce the dry ingredients to very fine powder, and when wanted for use, make them into a confection with the honey.

Use, &c. It is antispasmodic; in enemas 30 to

60 grs., with half a pint of gruel, for flatulent colic, &c.

CONFECTION OF SCAMMONY. *Syn.* ELECTUARIUM CARYOCOSTINUM, (P. L. 1720.) DITTO E SCAMMONIO, (P L. 1745.) DITTO SCAMMONII, (P. L. 1809 and 1788.) CONFECTIO SCAMMONEÆ, (P. L. 1809 and 1824.) *Prep.* (*Confectio Scammonii* P. L.) Scammony ℥iss; cloves and ginger, of each, ʒvj; oil of caraway f3ss. Reduce the ingredients to a very fine powder, and when wanted for use, make them into a confection with sirup of roses, and lastly add the oil.

Use, &c. Cathartic in doses of 10 to 30 grs.

CONFECTION OF SENNA. *Syn.* LENITIVE ELECTUARY. ELECTUARIUM SENNÆ, (P. L. 1788.) CONFECTIO SENNA, (P. L. 1809, and since.) *Prep.* (P. L.) Senna ℥viij; figs lb. j; pulp of tamarinds, prunes, and cassia, of each, lb. ss.; coriander seeds ℥iv; liquorice ℥iij; sugar lb. iiss; water 3 pints. *Proc.* Rub the senna and coriander in a mortar, and separate by sifting ℥x of the mixed powders. Boil the figs and liquorice in the water, until reduced to one half; then press and strain the liquor. Evaporate the strained liquor until only 24 fluid ounces remain, then add the sugar, and when dissolved, mix in the pulps, and lastly the powder.

Use, Dose, &c. Confection of senna is a gentle and pleasant purgative, and well adapted for persons suffering from piles, and as a laxative during pregnancy. The dose is ¼ to ½ oz. taken at bedtime or early in the morning.

Remarks. Perhaps there is no one pharmacopœial preparation which it is more difficult to obtain of good quality than the above. The absolute cost of an article prepared according to the directions of the College, will be somewhere about 1*s.* 9*d.* per lb.; but there are many wholesale drug houses vending confection of senna, which they warrant as genuine, at from 9*d.* to 1*s.* a pound. Dr. Paris (in his Pharmacologia) very truly remarks, that "the directions of the Pharmacopœia are very rarely followed." I understand that considerable quantities are manufactured, into which unsound and spoiled apples enter as a principal ingredient. The following forms are, to my knowledge, employed by some members of the trade.

II. Powdered senna, pulp of tamarinds, cassia, and prunes, of each, 1½ lb.; powdered corianders ¼ lb.; Spanish juice ½ lb.; simple sirup 12 lbs.

III. As the above, omitting the cassia pulp, and adding 2 lbs. more tamarind pulp.

Both these articles are labelled P. L., and sent out as genuine, and that when no competition as to price exists. The cheaper article is made as follows:

IV. Common prunes and tamarinds, of each, 16 lbs.; treacle ¾ cwt.; species (a compound of senna dust and small senna, mixed with 3 lbs. of coriander seeds, and strengthened with jalap, all ground to a fine powder) 18¼ lbs. To this is frequently added ¼ cwt. of rotten or inferior apples, which are pulped with the prunes and tamarinds. This article is not unfrequently labelled "CONF. SENNÆ VER." by the conscientious tradesman.

CONFECTION OF SULPHUR, (COMPOUND.) *Prep.* (St. B. H.) Precipitated sulphur ℥ss; cream of tartar ʒj; honey ℥j; mix As a laxative in piles, &c. *Dose.* ℥ss.

CONFECTION OF STEEL. *Syn.* CONFECTION OF CARBONATE OF IRON. *Prep.* Confection of orange-peel and sesquioxide of iron, (P. L.,) of each, 4 oz.; powdered white sugar 6 oz.; simple sirup 2 oz.; mix. Aromatic and tonic. *Dose.* A teaspoonful to ½ oz. twice or thrice daily.

CONGELATION, (from *congelo,* to freeze.) IN CHEMISTRY. The conversion of a liquid into a solid state, by the action of cold.

The production of an extreme degree of cold is often of the utmost importance in chemical operations, and an easy method of doing so is consequently a desideratum. The means hitherto adopted for this purpose have either depended upon the sudden liquefaction of solids, or the abstraction of heat by rapid evaporation. The loss of sensible heat, by the first method, is the basis of the various processes of producing cold by what are commonly called freezing mixtures, all of which act upon the principle of liquefying solid substances without supplying heat. The caloric of liquidity being in these cases derived from that previously existing in the solid itself in a sensible state, the temperature must necessarily fall. The degree of cold produced, depends upon the quantity of heat which is thus diffused through a larger mass, or which, as it were, disappears, and this is dependent on the quantity of solid matter liquefied, and the rapidity of the liquefaction. Saline compounds are the substances most frequently employed, and those which have the greatest affinity for water, and thus liquefy the most rapidly, produce the greatest degree of cold. Thus it is, that chloride of calcium and nitrate of ammonia, when dry and in fine powder, if suddenly mixed with water, produce extreme cold. The latter, suddenly mixed with an equal weight of water at 50°, will sink the thermometer to +4°, or 28° below the freezing point. The most common and convenient freezing mixture, when snow can be procured, is formed by mixing 2 parts of that substance with 1 part of sea-salt. This will sink the thermometer to —5°, or 37° below the freezing point of water. Equal parts of these substances produce a degree of cold marked by the zero of Fahrenheit's thermometer, and is the standard taken for graduating that instrument. Mr. Walker, a gentleman who fully investigated this subject, recommends the following proportions for the production of extreme cold.

sale druggist in the city, produces an excellent article.

II. Hay saffron, cassia, and turmeric, of each 4 oz.; cardamoms 1 oz.; starch 8 oz.; precipitated chalk 2 lbs.; white sugar 4 lbs.; oil of nutmegs 2 drachms; oil of cloves 3 drachms. Reduce the dry ingredients to fine powder, and pass it through an 80 hole sieve, then add the oils, and after well mixing, pass it through a coarse sieve, (about 40 holes to the inch,) to ensure the whole being perfectly mixed.

The following form produces a powder possessing great depth and brilliancy of color.

III. Hay saffron 4 oz.; turmeric 3 oz.; powdered starch 8 oz.; precipitated chalk 2 lbs.; white sugar 4 lbs.; oils of cloves and cassia, of each 3 drachms; oil of nutmegs 2 drachms; essence of cardamoms 1 oz. *Proc.* Boil the saffron and turmeric in 1 gallon of water, placed in a bright copper pan, for 10 minutes, then, without straining, add the chalk, starch, and sugar; mix well, and continue stirring until the mixture becomes quite stiff, then break it up and dry it until fit for powdering. This must be performed in a water or steam bath. To the powder, passed through a fine sieve, as before, the oils and tincture must be added, and after being well mixed, and passed through a coarse sieve, it should be placed in a jar or bottle, and bunged up close.

Remarks. In the wholesale trade this article is kept under two forms: one in powder, as ordered by the College, and commonly called, for distinction sake, "*pulvis confectionis aromaticæ;*" the other mixed up ready for use. In preparing the latter, it is a common plan to make a strong infusion or decoction of the saffron, and to use it to mix up the other ingredients. Some persons follow the method described in the last formula, mixing up the powder to a proper consistence with water before adding the aromatics. When the price of *precipitated* chalk is an objection to its use, *prepared* chalk may be used instead. This confection is cordial, stimulant, and antacid. *Dose.* 10 to 60 grs.

CONFECTION OF BLACK PEPPER. *Syn.* WARD'S PASTE. *Prep.* (*Confectio Piperis Nigri*, P. L.) Black pepper and elecampane root, of each lb. j; fennel seed lb. iij; honey and white sugar, of each lb. ij; mix.

Remarks. The common practice is to keep the dry ingredients ready mixed in a bottle, and only to add the honey as wanted. The proportions are 2 parts of the latter to 7 of the mixture. The *dose* is 1 to 2 drachms 2 or 3 times a-day, in piles, fistula, &c. It should be persevered in for 2, 3, or 4 months, (Sir B. Brodie;) and as it is apt to accumulate in the bowels, its use should be accompanied by mild aperients. (Pereira.)

CONFECTIONS OF CASSIA. *Syn.* ELECTUARIUM CASSIÆ, (P. L. 1788.) *Prep.* (*Confectio Cassiæ*, P. L.) Fresh cassia pulp lb. ss.; manna ℥ij; tamarind pulp ℥j; sirup of roses f℥viij. Bruise the manna and dissolve it in the sirup, then add the pulps and evaporate to a proper consistence.

CONFECTION OF HEMLOCK. (Dr. Osborne.) *Prep.* Fresh leaves of hemlock and moist sugar equal parts; beat them to a confection in a mortar.

CONFECTION OF OPIUM. *Syn.* PHILONIUM ROMANUM, (P. L. 1720.) DITTO LONDINENSE, (P. L. 1745.) CONFECTIO OPIATA, (P. L. 1788.) DITTO OPII, (P. L. 1809, and since.) *Prep.* (P. L.) Powdered opium ʒvj; long pepper ℥j; ginger ℥ij; caraways ℥iij; tragacanth ʒij; all in fine powder; sirup f℥xvj. Mix.

Use and Dose. This confection is intended as a substitute for the *mithridate* and *theriaca* of the old Pharmacopœia. It is stimulant and narcotic, and is given in flatulent colic and diarrhœa unaccompanied by fever. The dose is from 15 to 50 grs.

CONFECTION OF ORANGE PEEL. *Syn.* CONSERVA FLAVEDINIS CORTICUM AURANTIORUM, (P. L. 1720 and 1745.) DITTO CORTICIS EXTERIORIS AURANTII HISPALENSIS, (P. L. 1788.) DITTO AURANTIORUM, (P. L. 1824.) DITTO AURANTII, (P. L. 1809 and 1836.) *Prep.* (P. L.) The external rind of the fresh orange, separated by rasping, lb. j; white sugar lb. iij. Beat the rind in a stone mortar with a wooden pestle, then add the powdered sugar, and beat the mixture until the two are perfectly incorporated.

Remarks. This confection is tonic and stomachic, and is principally used as a vehicle for the exhibition of tonic powders.

CONFECTION OF PEPPERMINT. *Prep.* Green peppermint 4 oz.; powdered white sugar 12 oz.; beat them together as last.

Use. Anti-emetic and flatulent. Given in colic, &c., in the form of a bolus, or made into a mixture.

CONFECTION OF THE DOG ROSE. *Syn.* CONFECTION OF HIPS. CONSERVA FRUCTUS CYNOSBATI, (P. L. 1720 and 1745.) DITTO CYNOSBATI, (P. L. 1788.) DITTO ROSÆ CANINÆ, (P. L. 1809, and since.) *Prep.* (P. L.) Pulp of the dog rose lb. j; powdered refined sugar ℥xx; mix by a gentle heat in an earthen vessel.

II. Pulped hips 2 cwt.; fine white sugar 2½ cwt.; incorporate them without applying heat.

Remarks. Both this and the following confection has a brighter color, if made without heat, or touching metallic vessels. On the small scale it is made by beating the ingredients together in a marble mortar, but in large quantities by grinding in a mill. It is slightly laxative, and is principally used for forming pills. It candies by keeping.

CONFECTION OF THE RED ROSE. *Syn.* CONSERVA ROSARUM RUBRARUM, (P. L. 1745.) DITTO ROSÆ, (P. L. 1788.) DITTO ROSÆ GALLICÆ, (P. L. 1809 and 1824.) CONFECTIO ROSÆ GALLICÆ, (P. L. 1836.) *Prep.* (P. L.) Petals of the red rose lb. j; refined sugar lb. iij; beat the petals in a stone mortar, then add the sugar, and again beat until thoroughly incorporated.

Remarks. On the large scale this is prepared like the confection of hips. It is astringent and tonic, and principally used for forming pills. If taken alone, the dose is 1 to 2 drachms.

CONFECTION OF RUE. *Syn.* ELECTUARIUM E BOCCIS LAURI, (P. L. 1720, 1745.) CONFECTIO RUTÆ, (P. L. 1809, and since.) *Prep.* (P. L.) Dried rue, caraway, and laurel berries, of each ℥iss; sagapenum (true) ℥ss; black pepper ʒij; honey ℥xvj. Reduce the dry ingredients to very fine powder, and when wanted for use, make them into a confection with the honey.

Use, &c. It is antispasmodic; in enemas 30 to

60 grs., with half a pint of gruel, for flatulent colic, &c.

CONFECTION OF SCAMMONY. *Syn.* ELECTUARIUM CARYOCOSTINUM, (P. L. 1720.) DITTO E SCAMMONIO, (P L. 1745.) DITTO SCAMMONII, (P. L. 1809 and 1788.) CONFECTIO SCAMMONEÆ, (P. L. 1809 and 1824.) *Prep.* (*Confectio Scammonii* P. L.) Scammony ℥iss; cloves and ginger, of each, ʒvj; oil of caraway fʒss. Reduce the ingredients to a very fine powder, and when wanted for use, make them into a confection with sirup of roses, and lastly add the oil.

Use, &c. Cathartic in doses of 10 to 30 grs.

CONFECTION OF SENNA. *Syn.* LENITIVE ELECTUARY. ELECTUARIUM SENNÆ, (P. L. 1788.) CONFECTIO SENNA, (P. L. 1809, and since.) *Prep.* (P. L.) Senna ℥viij; figs lb. j; pulp of tamarinds, prunes, and cassia, of each, lb. ss.; coriander seeds ℥iv; liquorice ℥iij; sugar lb. iiss; water 3 pints. *Proc.* Rub the senna and corianders in a mortar, and separate by sifting ℥x of the mixed powders. Boil the figs and liquorice in the water, until reduced to one half; then press and strain the liquor. Evaporate the strained liquor until only 24 fluid ounces remain, then add the sugar, and when dissolved, mix in the pulps, and lastly the powder.

Use, Dose, &c. Confection of senna is a gentle and pleasant purgative, and well adapted for persons suffering from piles, and as a laxative during pregnancy. The dose is ¼ to ½ oz. taken at bedtime or early in the morning.

Remarks. Perhaps there is no one pharmacopœial preparation which it is more difficult to obtain of good quality than the above. The absolute cost of an article prepared according to the directions of the College, will be somewhere about 1*s.* 9*d.* per lb.; but there are many wholesale drug houses vending confection of senna, which they warrant as genuine, at from 9*d.* to 1*s.* a pound. Dr. Paris (in his Pharmacologia) very truly remarks, that "the directions of the Pharmacopœia are very rarely followed." I understand that considerable quantities are manufactured, into which unsound and spoiled apples enter as a principal ingredient. The following forms are, to my knowledge, employed by some members of the trade.

II. Powdered senna, pulp of tamarinds, cassia, and prunes, of each, 1½ lb.; powdered corianders ¾ lb.; Spanish juice ½ lb.; simple sirup 12 lbs.

III. As the above, omitting the cassia pulp, and adding 2 lbs. more tamarind pulp.

Both these articles are labelled P. L., and sent out as genuine, and that when no competition as to price exists. The cheaper article is made as follows:

IV. Common prunes and tamarinds, of each, 16 lbs.; treacle ¾ cwt.; species (a compound of senna dust and small senna, mixed with 3 lbs. of coriander seeds, and strengthened with jalap, all ground to a fine powder) 18¾ lbs. To this is frequently added ¼ cwt. of rotten or inferior apples, which are pulped with the prunes and tamarinds. This article is not unfrequently labelled "CONF. SENNÆ VER." by the conscientious tradesman.

CONFECTION OF SULPHUR, (COMPOUND.) *Prep.* (St. B. H.) Precipitated sulphur ℥ss; cream of tartar ʒj; honey ℥j; mix As a laxative in piles, &c. *Dose.* ℥ss.

CONFECTION OF STEEL. *Syn.* CONFECTION OF CARBONATE OF IRON. *Prep.* Confection of orange-peel and sesquioxide of iron, (P. L.,) of each, 4 oz.; powdered white sugar 6 oz.; simple sirup 2 oz.; mix. Aromatic and tonic. *Dose.* A teaspoonful to ½ oz. twice or thrice daily.

CONGELATION, (from *congelo,* to freeze.) IN CHEMISTRY. The conversion of a liquid into a solid state, by the action of cold.

The production of an extreme degree of cold is often of the utmost importance in chemical operations, and an easy method of doing so is consequently a desideratum. The means hitherto adopted for this purpose have either depended upon the sudden liquefaction of solids, or the abstraction of heat by rapid evaporation. The loss of sensible heat, by the first method, is the basis of the various processes of producing cold by what are commonly called freezing mixtures, all of which act upon the principle of liquefying solid substances without supplying heat. The caloric of liquidity being in these cases derived from that previously existing in the solid itself in a sensible state, the temperature must necessarily fall. The degree of cold produced, depends upon the quantity of heat which is thus diffused through a larger mass, or which, as it were, disappears, and this is dependent on the quantity of solid matter liquefied, and the rapidity of the liquefaction. Saline compounds are the substances most frequently employed, and those which have the greatest affinity for water, and thus liquefy the most rapidly, produce the greatest degree of cold. Thus it is, that chloride of calcium and nitrate of ammonia, when dry and in fine powder, if suddenly mixed with water, produce extreme cold. The latter, suddenly mixed with an equal weight of water at 50°, will sink the thermometer to +4°, or 28° below the freezing point. The most common and convenient freezing mixture, when snow can be procured, is formed by mixing 2 parts of that substance with 1 part of sea-salt. This will sink the thermometer to —5°, or 37° below the freezing point of water. Equal parts of these substances produce a degree of cold marked by the zero of Fahrenheit's thermometer, and is the standard taken for graduating that instrument. Mr. Walker, a gentleman who fully investigated this subject, recommends the following proportions for the production of extreme cold.

TABLES *exhibiting a collective View of all the* FRIGORIFIC MIXTURES *contained in* MR. WALKER'S *Publication*, 1808.

TABLE I. Consisting of Frigorific Mixtures, composed of Ice, with Chemical Salts and Acids.

Mixtures		Thermometer sinks.	Degree of cold produced.
Snow or pounded ice Muriate of soda	2 parts 1 "	From any temperature to —5°	*
Snow or pounded ice Muriate of soda Muriate of ammonia	5 " 2 " 1 "	From any temperature to —12°	*
Snow or pounded ice Muriate of soda Muriate of ammonia Nitrate of potash	24 " 10 " 5 " 5 "	From any temperature to —18°	*
Snow or pounded ice Muriate of soda Nitrate of ammonia	12 " 5 " 5 "	From any temperature to —25°	*
Snow Diluted sulphuric acid†	3 " 2 "	From +32° to —23°	55°
Snow Muriatic acid (concentrated)	8 " 5 "	From +32° to —27°	59
Snow Concentrated nitrous acid	7 " 4 "	From +32° to —30°	62
Snow Muriate of lime	4 " 5 "	From +32° to —40°	72
Snow Crystallized muriate of lime	2 " 3 "	From +32° to —50°	82
Snow Potash	3 " 4 "	From +32° to —51°	83

N. B. The reason for the omissions in the last column of this table is, the thermometer sinking in these mixtures to the degree mentioned in the preceding column, and never lower, whatever may be the temperature of the materials at mixing.

TABLE II. Consisting of Frigorific Mixtures, having the power of generating or creating Cold, without the aid of Ice, sufficient for all useful and philosophical purposes, in any part of the world at any season.

Mixtures.		Thermometer sinks.	Degree of cold produced.
Muriate of ammonia Nitrate of potash Water	5 parts 5 " 16 "	From +50° to +10°	40°
Muriate of ammonia Nitrate of potash Sulphate of soda Water	5 " 5 " 8 " 16 "	From +50° to +4°	46
Nitrate of ammonia Water	1 " 1 "	From +50° to +4°	46
Nitrate of ammonia Carbonate of soda Water	1 " 1 " 1 "	From +50° to —7°	57
Sulphate of soda Diluted nitrous acid‡	3 " 2 "	From +50° to —3°	53
Sulphate of soda Muriate of ammonia Nitrate of potash Diluted nitrous acid	6 " 4 " 2 " 4 "	From +50° to —10°	60

† Strong acid 2 parts; water or snow 1 part, by weight.
‡ Fuming nitrous acid 2 parts; water 1 part, by weight.

Table II. continued.

Mixtures.	Thermometer sinks.	Degree of cold produced.
Sulphate of soda . . . . 6 parts Nitrate of ammonia. . . . 5 " Diluted nitrous acid . . . . 4 "	From +50° to —14°	64°
Phosphate of soda . . . . 9 " Diluted nitrous acid . . . . 4 "	From +50° to —12°	62
Phosphate of soda . . . . 9 " Nitrate of ammonia . . . . 6 " Diluted nitrous acid. . . . 4 "	From +50° to —21°	71
Sulphate of soda . . . . 8 " Muriatic acid . . . . 5 "	From +50° to 0°	50
Sulphate of soda . . . . 5 " Diluted sulphuric acid* . . . 4 "	From +50° to +3°	47

N. B. If the materials are mixed at a warmer temperature than that expressed in the Table, the effect will be proportionately greater; thus, if the most powerful of these mixtures be made when the air is +85°, it will sink the thermometer to +2°.

TABLE III. Consisting of Frigorific Mixtures selected from the foregoing Tables, and combined so as to increase or extend Cold to the extremest Degrees.

Mixtures.	Thermometer sinks.	Degree of cold produced.
Phosphate of soda . . . . 5 parts Nitrate of ammonia. . . . 3 " Diluted nitrous acid . . . . 4 "	From 0° to —34°	34°
Phosphate of soda . . . . 3 " Nitrate of ammonia . . . . 2 " Diluted mixed acids. . . . 4 "	From —34° to —50°	16
Snow . . . . 3 " Diluted nitrous acid. . . . 2 "	From 0° to —46°	46
Snow . . . . 8 " Diluted sulphuric acid . . . 3 " Diluted nitrous acid . . . . 3 "	From —10° to —56°	46
Snow . . . . 1 " Diluted sulphuric acid . . . . 1 "	From —20° to —60°	40
Snow . . . . 3 " Muriate of lime . . . . . 4 "	From +20° to —48°	68
Snow . . . . 3 " Muriate of lime . . 4 "	From +10° to —54°	64
Snow . . . . 2 " Muriate of lime . . . 3 "	From —15° to —68°	53
Snow . . . . 1 " Crystallized muriate of lime. . 2 "	From 0° to —66°	66
Snow . . . . 1 " Crystallized muriate of lime. . 2 "	From —40° to —73°	33
Snow . . . . 8 " Diluted sulphuric acid . . . 10 "	From —68° to —91°	23

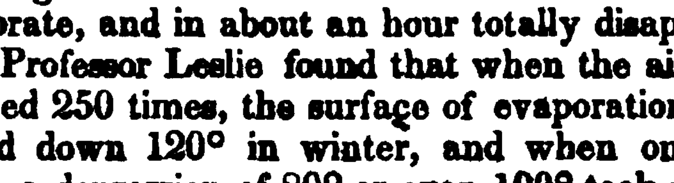
Remarks. The above artificial processes for the production of cold are more effective when the ingredients are first cooled by immersion in other freezing mixtures. In this way Mr. Walker succeeded in producing a cold equal to 100° below the zero of Fahrenheit, or 132° below the freezing point of water.

The materials in the first column are to be cooled, previously to mixing, to the temperature required, by mixtures taken from either of the preceding tables.

* Equal weights of strong acid and water.

II. (*By evaporation.*) When heat passes from the sensible to the insensible state, as in the formation of vapor, cold is generated. This may be illustrated by pouring a few drops of ether, or highly rectified alcohol, on the palm of the hand, when a strong sensation of cold will be produced. In like manner, if the bulb of a thermometer be covered with lint, and the latter moistened with ether, the quicksilver will rapidly fall. Even in hot climates water is frozen by the joint operation of evaporation and radiation. The natives of India procure ice when the temperature of the air much exceeds the freezing point. On the open plains, near Calcutta, this is effected by exposing a thin stratum of water to the atmosphere, during the fine clear nights of December, January, and February. The pans are made of porous earthenware, and water is poured in to the depth of about $1\frac{1}{2}$ inches. A large number of vessels of this kind are arranged in an excavation in the ground, 30 or 40 feet square and 2 feet deep, the bottom of which is covered, to the depth of 10 or 12 inches, with sugar canes or the stalks of Indian corn. At sunrise the pans are visited, the ice separated from the water, and packed as tight as possible in a deep cavity or pit, well screened from the heat.

It has been found that evaporation proceeds much more rapidly from the surface of fluids in a vacuum than in the atmosphere. Dr. Cullen was the first person to apply this practically. In 1755 he plunged a vial of ether into a tumbler of water, and on placing it under a receiver and exhausting the air, the ether boiled and the water was speedily frozen. In 1777, Mr. Nairne published his method of rendering the rarefied atmosphere of an exhausted receiver free from aqueous vapor by means of sulphuric acid. By the application of this discovery, Professor Leslie in 1810 succeeded in freezing water with great ease. This he effected by introducing a surface of sulphuric acid under the receiver of an air-pump, over which he placed a watch-glass filled with water, so that the vapor arising from the latter was rapidly absorbed by the former. After a few strokes of the piston the water was converted into a solid cake of ice, which on being left in the rarefied medium continued to evaporate, and in about an hour totally disappeared. Professor Leslie found that when the air was rarefied 250 times, the surface of evaporation was cooled down 120° in winter, and when only 50 times, a depression of 80° or even 100° took place. A pleasing philosophical toy, illustrative of the evaporative power of a vacuum, is the Cryophorus, or frost-bearer of Dr. Wollaston. This instrument consists of two small glass globes united by a tube, one of which is partly filled with water, but the apparatus is perfectly free from air.



The part of the apparatus unoccupied by the water, though apparently empty, is in reality filled with aqueous vapor, and thus checks evaporation by its pressure on the surface of the water. No sooner is the pressure removed, as by plunging the empty ball into a freezing mixture, (which condenses the vapor,) than rapid evaporation commences, and the water in the other ball is frozen in two or three minutes.

To succeed well in the production of cold in this way, it is necessary that the surfaces of the two fluids should be pretty near together, and that the acid should have the greater amount of surface of the two. The acid should be poured to the depth of $\frac{1}{2}$ an inch into a broad shallow dish or capsule, and the water into another vessel of a similar kind, but having only half the diameter of the former, and proportionally shallow. The smaller capsule may be supported over the surface of the larger one by means of 3 slender feet. As soon as the acid has acquired one-tenth of its weight of water, its absorbent power is diminished $\frac{1}{100}$; when this dilution reaches $\frac{1}{4}$ the reduction is $\frac{1}{25}$, and when it reaches $\frac{1}{2}$ the cooling power has diminished about 50%. "Sulphuric acid is capable of congealing more than 20 times its weight of water before it has imbibed nearly its own bulk of that liquid, or has lost about $\frac{1}{8}$ of its refrigerating power." (Ure.) Sulphuric acid, which has become diluted in this way, may be reconcentrated by heat.

It has been discovered that oatmeal, dried nearly to brownness before a common fire, and cooled in close vessels, may be substituted for sulphuric acid. With a quantity of this substance, one foot diameter, and 1 inch deep, Professor Leslie froze 1 imperial pint of water, contained in a hemispherical porous cup. Ignited chloride of calcium, in porous pieces, has also been successfully used for the same purpose. Dr. Ure has found that a requisite vacuum may be produced by the agency of steam, in the following manner, without the use of an air-pump: "A cast-iron drum of considerable dimensions being filled with steam by heating a small quantity of water in it, will sufficiently expel the air. When it is cooled by the affusion of water, a transferrer plate being attached to the stopcock on its upper surface would easily enable us, without any air-pump, to effect congelation by means of sulphuric acid in the attenuated atmosphere. Suppose the capacity of the receiver to be one-sixtieth of the iron cylinder, an aëriform rarefaction to this degree would be effected in a moment by a turn of the stopcock; and, on its being returned, the moisture below would be cut off, and the acid would speedily condense the small quantity of vapor which had ascended."

Many curious experiments may be performed over sulphuric acid, in the receiver of an air-pump, among which one of the most instructive and amusing is the congelation of quicksilver, a metal which requires, for this purpose, a temperature of 39° below zero, or 71° below the freezing point of water. This is readily effected by suspending the metal in a capsule of ice by means of threads, near to the surface of the sulphuric acid, and urging the rarefaction as much as possible. Mercury so frozen may be kept in the solid state for several hours.

The processes of congelation above detailed admit of being applied to several useful purposes, especially in domestic economy, and the arts of the cook and confectioner, as in the making of ices, &c.

CONGREVE MATCHES. I. (*Process of M. Jeblonouski.*) Put phosphorus 40 grammes into a wide-mouthed vial, with enough oil of turpentine to cover it, add flowers of sulphur 10 gr.,

and put the vial into hot water, (using great caution,) until the phosphorus is melted. Then cork close and agitate until cold, when any supernatant spirits of turpentine must be poured off. Into this pulpy mass the extremities of the matches are dipped, and when they have become *rather* dry, they are again dipped into the following mixture: Gum arabic 30 grammes, (dissolved in a little water;) chlorate of potassa 20 grammes; soot, or vermilion, (rubbed up with a few drops of alcohol,) 10 gr.; mix, and dip the tips of the matches therein as before, then dry them cautiously in a warm apartment. These matches inflame without fulmination (noise) on being rubbed against any rough surface.

II. (*Joblonouski.*) Chlorate of potassa 2 parts; phosphorus 4 parts; gum arabic 7 parts; gelatin 2 parts. *Proc.* The phosphorus is divided in the gum brought to the state of thick mucilage, and warmed; the gelatin is melted and added to the phosphoreted mucilage. The chlorate of potassa is bruised in a mortar, and at the same time moistened with the mucilage. When it is bruised the whole is mixed together, and a paste is obtained, with which matches, tipped with sulphur, may be embued. They are then dried in the air.

III. (*Process of Dr. R. Boettger.*) Gum arabic and vermilion, of each 16 parts; phosphorus 9 parts; saltpetre 14 parts. *Proc.* The phosphorus must be reduced to a state of fine division, by agitating it with fresh urine, or, still better, a solution of pure urea, which, in consequence of the discovery by Liebig, of a process of preparing that substance artificially, may now be easily procured or made. Hot water must be employed to melt the phosphorus, and this part of the process is similar to that previously detailed. The minutely divided phosphorus thus formed, is mixed with the other articles made into a paste, with the gum dissolved in the least quantity of water, and the matches dipped into the mingled ingredients and dried. They are then dipped into a dilute varnish of copal, or a thin solution of gum arabic containing saltpetre, and again dried. (Boettger's Beitrage.) These matches are very superior, and explode without noise.

Remarks. The matches formerly made, exploded with a crackling noise, and frequently threw out small sparks of fire, which rendered them dangerous. This arose from their containing too large a quantity of chlorate of potassa. An opposite plan is now generally followed, and a less proportion of the chlorate is used, or instead thereof saltpetre. The quantity of the igniting ingredients has also been greatly lessened, so as to avoid any danger on that account. This plan answers very well, when the body of the matches, whether of wood or pasteboard, is properly prepared; but if this be not the case, frequent disappointment will occur, from their going out again immediately after inflaming. To prevent this, the matches should be dipped into sulphur previously to coating them with the composition, unless intended for cigar fusees, when they should be prepared by soaking them in water holding some saltpetre, bichromate of potash, or acetate of lead in solution, preference being usually given to the first of these articles. Different coloring substances are employed to tint the composition, according to the fancy of the manufacturer, as smalts, red lead, vermilion, black oxide of manganese, soot, &c. A very elegant method of reducing phosphorus to a state of minute division, is to melt it in rectified spirit, and agitate until cold, as above.

The manufacture and sale of matches, containing sulphur and phosphorus, as in the first formula, have been forbidden in Paris, in consequence of the extreme facility with which they ignite, having led to several accidents. (See CHLORATE MATCHES, and LUCIFERS.)

CONIA. *Syn.* CONEINE. CONICIN. CICUTINE, &c. A poisonous alkaloid, discovered by Giesecke in hemlock.

Prep. Distil the seeds of hemlock, or their alcoholic extract, with water and potassa. During this process, the conia passes over into the receiver and floats upon the top of the water, which also contains a little conia in solution. It must be purified in the way directed for the volatile bases. (See ALKALOID.) If the alcoholic extract be employed, about ½ its weight of potassa should be used.

Remarks. 6 lbs. of fresh and 9 lbs. of dried seeds yielded 1 oz. of conia. (Gieger.) 40 lbs. of the ripe but green seeds yielded 2½ oz. of hydrated conia. (Christison.) It is remarkably poisonous. One drop, placed in the eye of a rabbit, killed it in 9 minutes. Five drops, poured into the throat of a dog, killed it in less than a minute. It has been employed in some convulsive and spasmodic diseases. "The plaintive cries, the contortions, and the rigidity of the limbs, which have always preceded death, (caused by conia,) leave no doubt as to the cruel pains which this kind of poisoning brings on." (Boutron-Chalard and Henry.)

CONSERVES. (From *conservo*, to keep.) In pharmacy, a composition of some recent vegetable matter and sugar, beat together to the consistence of a paste. The object aimed at in the preparation of conserves, is to preserve the properties of the active ingredient, which would otherwise be liable to change. In the last edition of the London Pharmacopœia, conserves, as well as electuaries, are included under the head of confections. The term confection appears, however, less appropriate to some of them, than the word conserve or electuary. The word confection has a more general application, and implies any sweetmeat or composition, in which sugar is the principal ingredient.

CONSERVE OF ALMONDS. (CONSERVA AMYGDALARUM, P. D.) Confection of almonds.

CONSERVE, ANTISCORBUTIC. (CONSERVA ANTISCORBUTICA. Selle.) Horseradish, water-cress, water-trefoil, radish juice, and orange juice, of each equal parts; white sugar enough to make a confection.

CONSERVE OF ARUM. (WAKEROBIN.) *Prep.* Fresh arum roots ½ lb.; white sugar 1½ lb.; beat together. Diuretic and attenuant.

CONSERVE OF LAVENDER. *Prep.* Lavender flowers 1 part; lump sugar 3 parts; beat together.

Remarks. In a similar way conserves are made from various other leaves and flowers; but mostly with only twice their weight of sugar. The above is frequently used to sweeten the breath.

CONSERVE OF LEMON-PEEL. *Prep* Rasp off the external rind of the lemon, and beat

it in a mortar with three times its weight of powdered white sugar. (See CONFECTION OF ORANGE-PEEL.) Tonic and stomachic.

CONSERVE OF ORANGE-PEEL. (CONSERVA AURANTII, P. E.) The same as the confection of orange-peel, P. L.

CONSERVE OF RED ROSES. (CONSERVA ROSÆ, P. E. and D.) That of the Dublin Pharmacopœia is the same as the confection of roses, P. L.; that of the Edinburgh has only 2 lbs. of sugar to 1 lb. of rose petals.

CONSERVE OF ROSEMARY. *Prep.* 1 part of the leaves or tops, beaten up with 3 parts of sugar.

CONSERVE OF SCURVY GRASS. *Syn.* CONSERVA COCHLEARIÆ HORTENSIS. *Prep.* Beat 1 lb. of the leaves with 3 lbs. of lump sugar. Stimulant and antiscorbutic.

CONSERVE OF SLOES. *Syn.* CONSERVA PRUNI SYLVESTRIS, (P. L. 1788.) Pulp of sloes 1 part; sugar 3 parts; mix.

CONSERVE OF SQUILLS. *Syn.* CONSERVA SCILLÆ, (P. L. 1788.) Fresh squills ℥j; white sugar ℥v; mix. Diuretic; attenuant.

CONSERVE OF TAMARINDS. *Syn.* CONSERVA TAMARINDORUM. *Prep.* (P. Cod.) Pulp of tamarinds 4 oz.; white sugar 6 oz.; heat by a water-bath in an earthen vessel, until mixed and of a due consistence.

CONSERVE OF WORMWOOD. *Syn.* CONSERVA ABSINTHII MARITIMI, (P. L. 1788.) *Prep.* Beat fresh-picked leaves of sea wormwood in a marble mortar, with a wooden pestle, first alone, and then with 3 times their weight of refined sugar.

CONSTIPATION, (OF THE BOWELS.) Costiveness. When this is merely accidental or occasional, a dose of some cathartic is the only treatment necessary, but when it is *habitual*, it calls for further attention. The common causes of constipation are—The use of bread containing alum, and water containing lime; and the want of sufficient exercise. The treatment should consist in adopting a diet free from astringents, and consisting of a large portion of green vegetables and ripe fruit. Brown bread is frequently eaten for this purpose, and acts by the laxative nature of the bran it contains. The *occasional* use of laxative and emollient enemata may be had recourse to, but their habitual administration, as well as that of purgative medicines, by the mouth, is not to be recommended. The bowels, accustomed to the continual use of stimulants, act but languidly, or scarcely at all, without their application. In females, especially of the higher classes, the want of proper exercise is generally the chief cause of constipation. With such persons, a short walk two or three times daily will often do wonders, particularly if a little ripe fruit, a few raisins or tamarinds, or 2 or 3 drum figs, be occasionally eaten.

COPAIBA. *Syn.* CAPIVI. BALSAM OF CAPIVI. The best copaiba is that imported from Maracaibo and St. Martha, and is packed in casks containing from 1 to 1½ cwt. each, in large bottles, or in cylindrical tin boxes. Considerable variation exists in the color, consistence, and sp. gr., as well as in the proportion of oil and resin yielded by different samples, scarcely any two of which exactly agree. Even the odor, taste, and transparency vary considerably. Brazilian capivi is thin, clear, and pale; while the West Indian is thick, golden yellow, less transparent, and has a less agreeable and somewhat terebinthinate smell. Some varieties are opaque, and continue so, unless filtered. This is a most troublesome operation, unless well managed, and without proper precautions, frequently proves useless. The opacity generally arises from the presence of water, which is frequently found mixed with copaiba when first imported. This it retains with great tenacity. The following is the plan I have found to answer on the large scale. Place the casks upon their ends in a warm situation, and leave them so for a fortnight, or longer, if convenient. They may then be tapped *a little above the bottom*, when some of them will generally be found quite transparent, and may be drawn off and vatted, care being taken to avoid shaking up the bottom. Those that are foul must be filtered through one or more long Canton flannel bags, sunk in the bottom of a tin cistern, placed over a suitable receiver; a few pounds of coarsely-powdered charcoal being mixed up with the first 5 or 6 gallons thrown in. This will rapidly fill up the pores of the bag, and make the balsam flow clear and pale. The first runnings should be returned until it becomes perfectly transparent. The bottoms of the casks, containing the water or impurities, may be poured into a large can or jar, and allowed to deposite for a few days, when the copaiba may be poured off the top, and filtered. A sudden change of temperature will frequently turn a brilliant sample of this article opaque or milky; it is not, therefore, deemed fit to send out by the wholesale trade, unless it will "*stand*" this test. To ascertain this point, a common practice is to fill a small bottle with the copaiba, and to leave it out of doors all night in an exposed situation. (See also BALSAM OF COPAIBA.)

COPAIBA, ALKALINE TINCTURE OF. (LEWIS THOMPSON.) *Prep.* Dissolve 2 oz. of carbonate (formerly subcarbonate) of potassa in 1 pint of water, and add to this, balsam of copaiba in a thin stream, constantly stirring the mixture, until this, at first white and milky, becomes clear like jelly or amber, which will generally take place when about a pint of balsam has been added; set the mixture aside for two or three hours, then pour in two pints of spirit of wine, and mix the whole together; the solution is then fit for use, and may be flavored with any of the essential oils. Sweet spirit of nitre may be substituted for spirit of wine; but it is necessary to destroy its acidity by distillation from lime or potassa, otherwise a decomposition will take place.

This solution is compatible with iodide of potassium and nitrate of potassa, but is decomposed by all earthy, metallic, and ammoniacal salts, such as sulphate of magnesia, chloride of iron, acetate of ammonia, &c., which must not, therefore, be administered in conjunction with it. (Chemist, iv 510.)

COPAIBA AND KALI. *Prep.* Carbonate of potassa and water, of each equal parts; dissolve, and add gradually transparent balsam of copaiba until the fluid, at first milky, turns quite clear

COPAIBA CAPSULES. Gelatinous capsules filled with balsam of copaiba.

COPAIBA AND RHATANY, CAPSULES OF. Ricord has recommended capsules of copaiba, coated with extract of rhatany, as much superior to the common ones of copaiba alone, in the treatment of blenorrhœa. They may be easily prepared by either of the two following methods:

1. By immersing, for an instant, the common capsule in the following composition: or,

2. By forming the bodies of the capsules with the *composition*, instead of with *gelatin*, and following the same manipulations as for the manufacture of the common gelatin capsules.

The Rhatany Composition. Extract of rhatany, newly prepared from the root, 3 parts; sirup of moist sugar 1 part; mucilage of gum arabic 1 part. Melt the extract and reduce it in a water bath until sufficiently stiff, when cold; do the same with the sirup and gum; then mix them together while hot, but only in such quantity as may be used at one time.

These capsules are said to sit well upon the stomach, the tone of which they contribute to improve.

COPAIBA, MISCIBLE. *Prep.* Mix transparent balsam of copaiba with half its volume of liquor of potassa of double strength.

Remarks. Different samples of balsam often require *slightly* different quantities of the solution of potassa; it is therefore best to mix them gradually and cautiously together. Should the mixture be opaque, a *little* more, of one or other of the ingredients, as the case may be, will render it clear. No heat should be used. This article is miscible with water, with which it forms a kind of milk; and from containing *all* the volatile oil of the copaiba is a very valuable preparation. Its activity is considered equal to the balsam itself, and it is given in similar doses.

COPAIBA, MIXTURE OF. (Chopart.) *Prep.* Copaiba, alcohol, sirup of Tolu, peppermint water, orange-flower water, of each ℥ij; sweet spirits of nitre ʒij. *Proc.* Rub the copaiba with the sirup until perfectly mixed, then add the spirits, and lastly the waters.

COPAIBA, SOLUBLE. *Prep.* I. Heat miscible copaiba to the boiling point, pour it while hot into a "*separator*," and place it in some situation where it will cool slowly. After a few days draw off the clear portion from a cock or hole placed *near* the bottom of the vessel, observing to stop the stream before any of the floating oil begins to flow through. *A very little* concentrated liquor of potassa added before applying the heat, will render it more soluble. *Prod.* Thick, clear, and soluble in *pure* water. Resembles copaiba in appearance.

II. Agitate balsam of copaiba with an equal measure of liquor of potassa, (P. L.;) boil for a few minutes in a clean tinned copper pan, then pour it into a separator, and proceed as before. Thinner than the last.

COPAIBA, SPECIFIC SOLUTION OF. (Frank's.) *Prep.* I. Balsam of copaiba 2 parts; liquor of potassa (P. L.) 3 parts; water 7 parts; boil it for 2 or 3 minutes, put it into a separator, and allow it to stand for 5 or 6 days, then draw it off from the bottom, avoiding the upper stratum of oil. To the clear liquid add 1 part of sweet spirits of nitre, perfectly free from acid, to which a few drops of liquor of potassa has been added, until it slightly browns turmeric paper; should it turn foul or milky, a *very little* liquor of potassa will usually brighten it; if not, place it in a clean separator for a few days, and draw it off from the bottom as before, when it will be perfectly brilliant without filtering.

Remarks. Some persons add the sweet spirits of nitre while the solution is still hot, mix it in as rapidly as possible, and immediately cork or fasten up the vessel. This is a good way when the article is wanted in a hurry, but is objectionable from the loss of spirit thereby occasioned, and the danger, without care, of bursting the separator.

A receipt for this article, upon the authority of Battley, has been going the round of the pharmaceutical works for some years, but which produces a preparation not at all resembling "*Frank's specific solution.*" It is as follows: "Take 12 oz. of balsam of copaiba and 6 oz. of calcined magnesia; rub together, add a pint of proof spirit, filter, and then add ½ oz. of sweet spirits of nitre." (Gray's Supplement.) I have tried this formula, and I find the product to be a white tincture, scarcely flavored with copaiba, and perfectly limpid. No sooner is balsam of copaiba mixed with half its weight of magnesia, than the two unite, and produce a compound insoluble in spirit of wine. Such is the affinity of this earth for copaiba, (copaibic acid,) that it will even take it from caustic potassa. Thus I find the solution of this balsam, (containing potassa,) if filtered through blotting-paper, with a little magnesia, becomes so strongly alkaline as to materially injure its quality, while a glutinous mass is deposited upon the sides and bottom of the paper. I have been led to a notice of this subject, from well knowing that many druggists have adopted this formula, and have been disappointed with the results, which are, however, only such as might be reasonably anticipated.

COPAIBA, SALT OF. *Syn.* Sal Copaibæ. There are two preparations bearing this name, the one, copaibic acid, and the other, copaibate of an alkali. They are both sold at ridiculously high prices. The advertisement of one of these preparations is heralded in with the following pseudo-philosophical announcement:

"*This preparation* of copaiba, in its chemical and medical analogies, may be compared to quinine from bark, the former being the tonic of the mucous membranes, and the latter that of the dermoid structures.

"*This salt* contains all the properties of the balsam of copaiba in a very concentrated form, without its nauseating qualities, and from this circumstance it may be administered to the most delicate constitution."

It is the general opinion of medical men, that the active properties of copaiba reside in a volatile or essential oil, of which the *above preparation is destitute*. It is therefore difficult to conceive how, in *this* instance, the reverse should be the case. I can speak from my own experience, and that of several high authorities to whom I have referred, that both the viscid and acid resins of copaiba are almost inert, and that all the alkaline preparations of these substances are nearly similar. I have taken the "sal copaibæ" myself, and have watched its action on others, but have not been able to

perceive any good effects to result from its administration.

COPAIBIC ACID. *Syn.* Capivic Acid. The yellow brittle resin of balsam of copaiba. It is prepared by digesting the resin (left after distilling the oil from the balsam) in alcohol, which dissolves the acid resin, but leaves the viscid one. It may be purified by re-solution in alcohol. It forms about 50% of the balsam.

Prop. An amber-colored, brittle, semi-crystalline, resinous substance, soluble in alcohol, ether, and oils, reddens litmus paper, and forms salts with the bases, called copaivates. These may generally be made by dropping into a solution of the acid in alcohol, an alcoholic solution of a soluble salt of the base. The copaivates of potash, soda, and ammonia are easily prepared, by adding to an alcoholic solution of the acid another of the pure alkali, until it be neutralized, when the salts may be obtained by careful evaporation. Copaivate of silver is formed by neutralizing the acid with nitrate of silver, both being dissolved in alcohol, and then adding a little liquor of ammonia, when a white crystalline precipitate will subside. The copaivates of lead, lime, and iron, as well as several others, may be made in a similar manner.

Copaivate of magnesia may be made by adding copaivate of potassa to a solution of epsom salts. All these salts are easily decomposed by acids.

COPAL. *Syn.* Gum Copal. A resinous substance, which exudes spontaneously from the Rhus copallinum, and the Elæocarpus copalifer. When of good quality, it is too hard to be scratched by the nail, and has a conchoidal fracture. It dissolves with difficulty, and this, combined with its extreme hardness, renders it very valuable for making varnishes.

Solvents. I. *Caoutchoucine;* sparingly. II. Equal parts of *caoutchoucine* and *alcohol*, of ·825; freely soluble in the cold. III. *Absolute alcohol*, added gradually to the copal, previously rendered gelatinous by water of ammonia, assisting the union with heat. IV. *Alcohol* added to the copal, previously softened with ether. V. *Absolute alcohol* 1½ parts, digested on copal 1 part for 24 hours. (Unverdorben.) VI. *Alcohol*, to which a little camphor has been added. VII. *Ether;* and this solution may be diluted with alcohol. VIII. *Oils of rosemary* and *lavender*, (spike;) too expensive for general use. IX. *Copal*, heated until it fuses, acquires the property of dissolving in turpentine and alcohol. X. *Copal*, reduced to powder and exposed for some time to the air, also becomes soluble in alcohol and turpentine. XI. *Drying linseed oil*, at nearly the boiling point, dissolves copal, and will bear dilution with spirits of turpentine as soon as it has cooled sufficiently. This is the common way of making copal varnish. XII. *Ammonia* enables oil of turpentine to dissolve copal; but it requires such nice management of the fire, that it seldom succeeds completely. (Lewis.) XIII. *Powdered copal*, triturated with a little camphor, softens and becomes a coherent mass; and camphor, added either to alcohol or oil of turpentine, renders it a solvent of copal. ½ oz. of camphor is sufficient for 1 quart of oil of turpentine, which should be of the best quality; and the copal, about the size of a large walnut, should be broken into very small pieces, but not reduced to a fine powder. The mixture should be set on a fire so brisk as to make it boil almost immediately The vessel should be of tin or other metal, strong, shaped like a wine-bottle with a long neck, and capable of holding 2 quarts. The mouth should be stopped with a cork, in which a notch is cut to prevent the vessel from bursting. (Sheldrake.) XIV. A good varnish may be made by pouring upon the purest lumps of copal, reduced to a fine mass in a mortar, colorless spirits of turpentine, to about one third higher than the copal, and triturating the mixture occasionally in the course of the day. Next morning it may be poured off into a bottle for use. Successive portions of oil of turpentine may thus be worked with the same copal mass. (Varley, Tilloch's Mag. 51.)

⁂ In all the above cases the copal should be reduced to a *coarse* powder. A *fine* powder is apt to stick together and form hard lumps. The solution of copal, even in its most ready solvents, is attended with some difficulty, and frequently miscarries in the hands of the inexperienced. A mixture of caoutchoucine and alcohol (as in No. II.) is an exception.

COPAL, MELTED. Obtained by holding the gum before a good fire, so that as soon as the copal melts, it may drop into a pan of water: a kind of oil separates from it, and the copal becomes soluble in spirits of wine, and still more so if the melting is repeated.

COPAL, POWDERED. Copal reduced to powder and exposed to the air in a thin stratum, on sieves covered with paper, for 3 or 4 months. Soluble in alcohol.

COPPER. (From *cuprum*, a corruption of κύπρος, from the island of Cyprus, whence it was formerly brought.) A red-colored metal, too well known to require description.

Hist. Copper and its alloys appear to have been known to the most remote ages of antiquity. Brass, an alloy of copper, is mentioned by Moses (Job, xxviii.) upwards of 1600 years before the birth of Christ. (Hales.) This metal is found in the metallic state, and in combination with oxygen, sulphur, acids, and other minerals, and in the organic kingdom, in the ashes of plants, and in the blood of animals. (Sarzeau.) The copper of commerce is principally prepared from copper pyrites, a mixed sulphuret of iron and copper, found in Cornwall, and other parts of the world.

Prep. Copper is only prepared from its ores on the large scale. The copper pyrites is first roasted, and then smelted, by which process "*coarse metal*" is produced; this is again submitted to calcination and smelting, when "*fine metal*" is obtained. It afterwards undergoes the process of refining and toughening.

Prop. This metal is malleable and ductile. It has a specific gravity of 8·8 to 8·9, fuses at about 2000° Fahr., and volatilizes at higher temperatures. It forms numerous compounds, all of which are more or less poisonous.

Char. and Tests. The solutions of copper possess a blue or green color, and yield a blue precipitate with soda or potassa. Ammonia produces a bluish-white precipitate, soluble in an excess of the precipitant, forming a deep blue solution. Prussiate of potash gives a reddish-brown precipitate, sulphureted hydrogen and hydrosulphurets, a black

ma. · A polished iron plate, immersed in an acidulous solution of copper, becomes coated with that metal.

Estim. The quantity of copper present in any compound, may be estimated by throwing it down from its solution by pure potassa, after which it must be carefully collected, washed, dried, ignited, and weighed. This will give the quantity of the oxide from which its equivalent of metallic copper may be calculated; every 5 parts of the former being (as near as possible) equal to 4 of the latter. Copper may also be precipitated at once in the metallic state, by immersing a piece of polished steel into the solution, but this method will not give very accurate results. Copper may be separated from lead by adding sulphuric acid to the nitric solution, and evaporating to dryness, when water digested on the residuum will dissolve out the sulphate of copper, but leave the sulphate of lead behind. From this solution the oxide of copper may be thrown down as before. Copper may be separated from zinc by sulphureted hydrogen, which will throw down a sulphuret of copper, which may be dissolved in nitric acid, and treated as above.

Uses. The applications of copper in the arts are too well known to require notice. In medicine, 3 or 4 grains of the filings were formerly given in rheumatism, and to prevent hydrophobia.

Ant. Copper in the metallic state appears to be inert, but most of its compounds are poisonous. The antidotes are, the white of egg, milk, or flour mixed with water. Iron filings (Payen, Chevallier, Dumas) and the prussiate of potash have also been recommended. A drachm or more of the latter may be taken dissolved in water, and ½ oz. or more of the former, ad libitum. Sugar has also been proposed as an antidote. (Duval, Postel.)

COPPER, ALLOYS OF. With *zinc* copper forms *brass;* with *tin, bronze, bell,* and *cannon metal.* An alloy made with 100 parts of copper and 50 of tin, forms *speculum metal. White copper* is formed by the addition of metallic arsenic, and *German silver* is a mixture of nickel, zinc, and copper. See these articles in their alphabetical places.

COPPER, ACETATES OF. I. (*Neutral Acetate. Syn. Distilled Verdigris. Binacetate of Copper. Crystallized Verdigris.*) *Prep.* Dissolve verdigris in vinegar, with the aid of heat, and crystallize. It forms dark green or blue crystals.

II. (*Diacetate. Syn. Verdigris. Ærugo.*) Formed by exposing sheets of copper to the vapor of acetic acid, in a warm situation. (See VERDIGRIS.) It forms a green or bluish-green powder.

III. (*Sesquibasic Acetate.*) The blue portion of verdigris, soluble in water.

IV. (*Trisacetate.*) The green insoluble portion of verdigris.

COPPER, ARSENITE OF. *Syn.* SCHEELE'S GREEN. *Prep.* Mix a solution of 2 parts of sulphate of copper in 44 of water, with a solution of 2 parts of potash of commerce, and 1 of pulverized arsenious acid, also in 44 of water. Both solutions being warm, the first is to be gradually poured into the second. The grass-green insoluble precipitate is to be washed with water.

COPPER, AMMONIURETED. *Syn.* CUPRO-SULPHATE OF AMMONIA. AMMONIATED COPPER, (P. E.) *Prep.* (*Ammonio-sulphate of Copper,* P. L.) Sulphate of copper ℥j; sesquicarbonate of ammonia ℥iss. Rub them together until carbonic acid ceases to evolve, then wrap it up in bibulous paper and dry it in the air.

Prop. By heat ammonia is evolved, and oxide of copper remains. Its aqueous solution changes the color of turmeric, and a solution of arsenious acid renders it green. (P. L.)

Uses. Employed in pyrotechny. It has been given in doses of ½ to 5 grs. in chorea, epilepsy, hysteria, &c., but it is principally employed as an injection and as a collyrium, in opacity of the cornea.

Remarks. Great care must be taken in drying this article, as it is apt not only to lose a large portion of its weight, but become of an inferior color. Both the ingredients should be separately reduced to powder before mixing.

COPPER, BEAN-SHOT. *Prep.* Melt copper, and pour it in a small stream into boiling water. It is in small lumps like peas or beans, hence its name.

COPPER, BLANCHED. *Prep.* Fuse copper with $\frac{1}{16}$ of its weight of neutral arsenical salt, under a flux of calcined borax, charcoal, and powdered glass.

COPPER, CARBONATE OF. *Syn.* DICARBONATE OF COPPER. MINERAL GREEN. *Prep.* Add a solution of carbonate of soda or potassa to a hot solution of protosulphate of copper.

Remarks. The beautiful green mineral called *malachite,* is a hydrated dicarbonate of copper. If the solution of copper in the above formula be employed cold, the precipitate has a bluish-green color. (See VERDITER.)

COPPER, CHLORIDES OF. *Prep.* I. (*Subchloride. Syn. Dichloride of Copper. Resin of ditto. White muriate of ditto.*) Distil a mixture of 1 part of copper filings, with two parts of corrosive sublimate.

II. (*Chloride. Syn. Muriate of Copper. Hydrochlorate of ditto. Protochloride of ditto.*) Dissolve protoxide of copper in muriatic acid, evaporate and crystallize.

Remarks. This salt forms green needles, is deliquescent, soluble in alcohol, and when heated, (under 400°,) loses its water, and becomes anhydrous chloride of copper, and assumes the form of a yellow powder. The first of these preparations is sometimes called the protochloride or muriate; the second the deutochloride.

COPPER, CHROMATE OF. *Prep.* Precipitate a salt of copper, with neutral chromate of potash; or dissolve hydrated peroxide or carbonate of copper in chromic acid. Caustic ammonia dissolves this salt, forming a magnificent dark-green liquid, from which, by the admixture of spirit of wine, ammonio-chromate of copper, or cupro-chromate of ammonia, is disengaged in the form of a powder of a splendid, rather dark-green appearance. The readiest way of preparing this permanent and beautiful color, is to add solution of chromate of potash to ammoniacal sulphate of copper.

COPPER, FEATHER-SHOT. *Prep.* Melted copper, poured in a small stream into cold water. It forms small pieces, with a feathered edge, hence the name. It is used to make solution of copper.

hardness of the different substances is measured by the power they possess of cutting or scratching other substances.

GEMS, FACTITIOUS. These are made of very pure, fusible, transparent and dense glass, usually termed *paste* or *strass*, which is mostly formed of oxide of lead, potassa and silica, with small quantities of other ingredients to increase the brilliancy and clearness. The tints are imparted by the addition of metallic oxides. The beauty of artificial stones and gems, depends upon the tint of the *real* stones being exactly imitated, and upon proper care and skill being exercised in the cutting, polishing, and setting of them in their cases. All the colored glasses, and enamels, may be worked up into artificial gems. (See ENAMELS, FOILS, PASTES, &c.)

GENEVA. (From *genièvre*, juniper.) Hollands gin. (See HOLLANDS.)

GENTIANINE. A peculiar substance obtained by MM. Henry and Caventou from the root of the common officinal gentian, (gentiana lutea.)

Prep. I. Digest powdered gentian root in ether for 2 or 3 days with agitation, filter, evaporate, dissolve in alcohol, filter, and again evaporate; redissolve in alcohol or ether, filter, and crystallize.

II. Digest gentian root (in powder) in ether for two days and nights, filter, evaporate nearly to dryness; add alcohol to the yellow crystalline mass thus obtained until it no longer becomes colored; evaporate to dryness, redissolve in weak alcohol, filter, evaporate again to dryness; dissolve in water, add some calcined magnesia, boil, filter, digest the sediment in ether, and evaporate.

Remarks. Gentianine forms golden yellow crystals, scarcely soluble in water, very soluble in alcohol and ether. It is a strong aromatic bitter, in doses of gr. ij; the tincture is mostly used. According to the researches of Trommsdorff and Leconte, the above substance is composed of *gentisin*, *gentianite*, and sugar.

GENTIANITE. THE BITTER PRINCIPLE OF GENTIAN. It has not been obtained in a state of purity. It may be procured combined with a portion of sugar, by digesting the alcoholic extract of gentian in water, throwing down the gentisin with lead, passing sulphureted hydrogen through the liquid to remove any traces of lead, filtering and evaporating. It may be further purified by digestion in ether.

GENTISIN. *Syn.* GENTISIC ACID. This is obtained from the alcoholic extract of gentian by digestion in water, and in alcohol, evaporating the tincture, and treating the residuum with ether. By repeated re-solutions in alcohol it may be obtained under the form of pale yellow needles. It forms salts with the bases.

GILDING. *Syn.* DORURE, (*Fr.*) VERGOLDUNG, (*Germ.*) The art of covering the surfaces of bodies with a thin film of gold, for the purpose of increasing their durability or improving their appearance.

GILDING, BOOK. *The gilt letters and figures on the leather, cloth, and silk covers of books*, are formed by sprinkling or dusting finely powdered gum mastich over the surface to be gilded; an iron or brass tool bearing the design upon its face is then heated to a proper temperature, and pressed upon a piece of leaf gold, which slightly adheres to it; the two are then transferred to the cover, and the tool is gently pressed on it, by which means the mastich softens, and retains the gold. The loose gold and powdered mastich are then dusted off with a brush. The gold will adhere to leather without the use of mastich, but the gilding is conceived to be more durable when it is employed.

The edges of the leaves of books and reams of paper are first cut perfectly smooth in the cutting press, and then thinly washed with a solution of isinglass in weak spirit, or with a varnish made of 4 parts of Armenian bole and 1 part of powdered sugar-candy, mixed up to a proper consistence with white of egg. The coating is allowed to dry, and is then smoothed with a wet rag, after which the gold leaf is applied and polished with the burnisher.

GILDING, BUTTON. This species of gilding has been already noticed. (See p. 149.) I shall, therefore, only remark here, that when the process is properly conducted, 12 dozen (1 gross) of buttons, of one inch in diameter, may be perfectly gilded on both sides with only 5 grains of gold. By an Act of Parliament, which I believe is still unrepealed, this is the smallest portion of gold permitted to be used for a gross of buttons of the above size, but a less quantity than 5 grains is frequently employed. The mass of the *finest* kind of buttons, and other small articles, have, however, during the last few years been gilded by means of a solution of chloride of gold in bicarbonate of potassa. (See Elkington's PATENT GILDING.)

GILDING, BURNISHED. This is principally applied to the frames of pictures and mirrors, and to similar objects. It is performed by giving the wood, first, a coating of good size, and next, several successive coats of size thickened with finely-powdered whiting, Spanish white, or plaster of Paris, until a good face is produced; observing to let each coat become quite dry, and to rub it perfectly smooth with fine glass-paper, before the application of the following one. When the proper 'face' is obtained, the surface is thinly and evenly gone over with gold size, and when this is *nearly* dry, the gold leaf is applied and afterwards burnished.

GILDING, CHEMICAL. This term is applied to those methods of gilding in which the gold adheres to the surface from chemical affinity, and not from the intervention of some glutinous substance. The latter method is called, by way of distinction, "mechanical gilding."

GILDING, COLD. This is performed by softening, annealing, and polishing the articles (copper or brass) to be gilded, and then applying the following powder by friction with a piece of cork moistened with a solution of salt in water; after which the work is burnished with a piece of hematite or polished steel.—*Powder:* Pure gold 5 drs.; pure copper 1 dr.; nitro-muriatic acid 10 oz.; dissolve, imbue clean linen rags with the solution, dry, burn them and carefully collect the ashes, which contain the gold in a state of minute division.

GILDING, DISTEMPER. This is a method practised by the French, that resembles BURNISHED GILDING, excepting in being *vastly* more complicated. This, as well as Burnished Gilding, is applied to wood, plaster, and marble.

GILDING, ELKINGTON'S PATENT. *Syn.* Bonnet's Process. Anglo-German Gilding. *Proc.* 1. (*The Gilding liquid.*) Fine gold 5 oz. (troy;) nitro-muriatic acid 52 oz. (avoirdupois;) dissolve by heat, and continue the heat until red or yellow vapors cease to be evolved; decant the clear liquid into a suitable vessel; add *distilled* water 4 gallons; pure bicarbonate of potassa 20 lbs.; and boil for two hours. *** The nitro-muriatic acid is made with *pure* nitric acid (sp. gr. 1·45) 21 oz.; *pure* muriatic acid (sp. gr. 1·15) 17 oz.; and *distilled* water 14 oz.

2. (*The Gilding.*) The articles, after being perfectly cleaned from scale or grease, and receiving a proper *face*, are to be suspended on wires, dipped into the liquid *boiling hot* and moved about therein, when, in from a few seconds to a minute, depending on the newness and strength of the liquid, the requisite coating of gold will be deposited on them. By a little practice the time to withdraw the articles is readily known; the duration of the immersion required to produce any given effect gradually increases as the liquid weakens by use. When properly gilded, the articles are withdrawn from the solution of gold, washed in clean water, and dried; after which they undergo the usual operation of coloring, &c. (See Gilding, wash.) A dead appearance is produced by the application to the articles of a *weak* solution of nitrate of mercury previously to the immersion; or the *deadening* may be given by applying a solution of the nitrate to the *gilded* surface and then expelling the mercury by heat. (This process, though patented by Mr. Elkington in England, and claimed as *his own* invention, was in reality discovered and first practised by M. Bonnet, a foreigner.) Articles thus gilded do not bear friction and the operations of being put in color, (mise en couleur,) so well as those gilded by the mercurial process, or even by electricity.

GILDING, FRICTION. This consists in the application, by friction, of gold in a minutely divided state, to the surface of the copper or brass, previously cleaned and brightened. (See Gilding, Cold.)

GILDING, GRECIAN. *Proc.* Sal ammoniac and corrosive sublimate, equal parts, are dissolved in nitric acid, and a solution of gold made with this menstruum; after slight concentration the liquid is applied to the surface of silver, which immediately becomes black, but on being heated exhibits a gilded surface.

GILDING, JAPANNER'S. This is done by covering the surface with oil size thinned with spirits of turpentine, and then gently daubing on gold powder with a puff of wash-leather. This gives the appearance of frosted gold. (See Gilding Powder.)

GILDING, LEAF. This term is applied to the gilding of paper, vellum, &c., by applying leaf gold to the surface, previously prepared with a coating of gum-water, size, or white of egg. It is usually finished with an agate burnisher.

GILDING, LETTER. The letters of signboards and similar ornamental gilding for outdoor work, is done by first covering the design with yellow or gold-color paint, then with oil gold size, and when this is *nearly* dry applying the leaf-gold, observing to shield it properly from the wind, lest it be blown away or become crumpled before being properly attached. This gilding is usually varnished.

GILDING LIQUOR. *Syn.* Gilder's Pickle *Prep.* Alum and common salt, of each 1 oz.; purified nitre 2 oz.; water ½ pint; used to impart a rich color to gold surfaces, principally trinkets. Its application should not be too long continued, as it dissolves a small portion of the gold. For common purposes it is best used diluted with water

GILDING METAL. The metal employed for gilding is usually brass, or a mixture of brass and copper. The following alloys have been recommended:—

I. Copper 6 parts; brass 1 part.

II. Copper 4 parts; Bristol brass 1 part.

III. Copper 13 parts; old Bristol brass 3 parts; tin 14 parts.

GILDING OF LEATHER. The finer class of leather gilding has been already noticed under Book Gilding. For common work, *silver* leaf is usually applied to the surface, previously covered with size or white of egg, and after being burnished down and dried is covered with gold-colored lacquer. Tinfoil is frequently employed for inferior work, or such as is not required to be elastic.

GILDING, OIL. This species of gilding may be divided into several operations.—1. The surface is prepared by a coating of whitelead in drying oil. —2. Another coat is given, made with calcined whitelead or masicot ground in linseed oil and turpentine; 3 or 4 coats of this mixture are often given, observing to carefully smooth off each coat with pumice or shave grass before the application of the following ones.—3. The *Gold Color*, or paint, is next applied. It is usually very adhesive gold size, or the bottom of the pot or dish in which painters wash their brushes. For this purpose it is thoroughly ground and strained.—4. When the gold color becomes partially dry and sufficiently tenacious, the gold-leaf is applied and pressed on with a wad of cotton, wood, or a soft brush.—5. A thin coat of spirit varnish is now given, and the object is cautiously passed over a chafing dish of charcoal, observing to avoid stopping the motion of the piece while doing so, as it would then become discolored and blistered. The work is usually finished off with a coat of pale oil varnish. For outdoor gilding, the whole of the varnishing process is generally omitted. This species of gilding is applied to woodwork, plaster, metal, &c.

GILDING OF POLISHED METALS. I. *Polished iron and steel* may be readily gilded by applying an ethereal solution of gold to the surface with a camel-hair pencil. The ether flies off and leaves the surface coated with gold; it must then be polished with a burnisher. In this way, any fancy device or writing may be executed on steel or iron. This species of gilding is not, however, so durable as the following:—

II. Apply gold leaf to the surface of polished iron, steel, or copper, heated to a bluish tint, press it on gently with the burnisher, avoiding breaking or injuring the gold; again expose it to a gentle heat, and repeat the process with fresh leaves of gold, until the gilding has acquired a proper thickness; then let it cool and polish it with the burnisher. (See Gold, Liquid.)

GILDING OF PORCELAIN, GLASS, &c

This is performed by blending powdered gold with gum water and a little borax, and applying it by means of a camel-hair pencil; the article is then heated sufficiently hot in an oven or furnace, by which means the gum is burnt, and the borax vitrifying cements the gold to the surface. When cold it is polished off with a burnisher. Names, dates, or any fancy device may thus be permanently and easily fixed on glass, china, earthenware, &c.

GILDING OF SILK, &c. *Silks, satins, woollens, ivory, bone, &c.*, may be readily gilded by immersing them in a solution of nitro-muriate (terchloride) of gold, (1 of the salt to 3 or 4 of water,) and then exposing them to the action of hydrogen gas. The latter part of the process may readily be performed by pouring some diluted sulphuric acid, or zinc or iron filings, in a bottle, and placing it under a jar or similar vessel, inverted, at the top of which the articles to be gilded are to be suspended.

The foregoing experiment may be very prettily and advantageously varied as follows:—Paint flowers or other ornaments with a very fine camel-hair pencil, dipped in the above-mentioned solution of gold, on pieces of silk, satin, &c., and hold them over a Florence flask, from which hydrogen gas is evolved, during the decomposition of the water by sulphuric acid and iron filings. The painted flowers, &c. in a few minutes will shine with all the splendor of the purest gold. A coating of this kind will not tarnish on exposure to the air, or in washing.

GILDING OF SILVER. Silver is usually gilded by brushing it evenly over with an amalgam of gold, submitting it to heat and burnishing. (See GILDING, WASH.)

GILDING POWDER. *Syn.* GOLD POWDER. GOLD BRONZE. *Prep.* I. Heat an amalgam of gold until the mercury be all volatilized. If the quantity be considerable, the process should be so conducted as to save the mercury.

II. Dissolve gold in nitro-muriatic acid, then precipitate it with a solution of pure protosulphate of iron; wash and dry the powder. A good process.

III. Grind gold leaf with honey by means of a stone and muller, until reduced to an impalpable powder, then wash away the honey and dry the gold.

Uses, &c. Powdered gold is employed in gilding by the japanners and by artists. It is either sold in powder or made up into shells. (See GOLD POWDER.)

GOLD SHELLS. The previous article ground up with gum water, and spread upon the insides of shells. Used by artists.

GILDING SIZE. *Syn.* GILDER'S SIZE. GOLD SIZE. GOLD COLOR. *Prep.* I. (*Oil size.*) Drying or boiled oil thickened with yellow ochre, or calcined red ochre, and carefully reduced to the utmost smoothness by grinding. It may be thinned with oil of turpentine. Improves by age. Used for *oil* gilding.

II. (*Water size.*) Parchment or isinglass size, mixed with finely-ground yellow ochre. Used in *burnished* or *distemper* gilding.

GILDING, TALBOT'S PATENT. By this process, gilding, silvering, and platinizing are performed by adding a solution of gallic acid in water ether, or alcohol, to a solution of gold, silver or platina, and immersing therein the metallic substances to be gilded, which must be allowed to remain immersed until sufficiently coated. The articles must be well cleaned and polished before being placed in the solution.

GILDING, THREAD. *Gold thread* is merely a thread of yellow silk covered with a very thin flatted wire of gold, by means of a properly arranged revolving wheel.

GILDING, VARNISH. This is oil gilding applied to equipages, picture-frames, furniture, &c., the surface being highly varnished and polished before it receives the size or gold color; and after the gilding has become quite dry, a coat of spirit varnish, fumed with the chafing-dish as above, is applied, followed by 2 or 3 coats of the best copal varnish, after which the work is carefully polished with tripoli and water. (See FURNITURE, VARNISHED.)

GILDING VARNISH. *Syn.* GILDER'S VARNISH. GILDER'S WAX. *Prep.* Beeswax 4 oz.; verdigris and sulphate of copper, of each 1 oz.; mix.

II. Beeswax 4 oz.; verdigris, red ochre, and alum, of each 1 oz.; mix. Used to give a red gold color to water-gilding.

GILDING, VOLTAIC. Gilding by the moist way; or by communicating a negative electric state, by means of a feeble hydro-electric current to the metal which is sought to be gilded, and which is immersed in a dilute solution of gold.

Proc. I. Pour a neutral solution of chloride of gold, containing not more than from ½ to 1⅝ of gold into a glass cylinder, whose lower extremity is hermetically closed with moistened gut-skin, and introduce the cylinder into a vessel which contains some water very slightly acidulated with a few drops of sulphuric acid. The cylinder should be supported so as to prevent its lower surface from resting immediately on the bottom of the larger vessel. It is necessary to carefully clean, or even polish, the surface of the metal, whether of silver or brass, that we desire to gild, lest a portion of it should be left ungilt. To attain this end, it is sometimes advisable to place the metal for a few moments in contact with zinc, in dilute sulphuric acid, so that hydrogen may be disengaged on its surface; after which it must be well washed. In order to gild an object, it must be fixed or suspended by a platina wire, to the other extremity of which is attached a plate of zinc; this done, plunge the article to be gilt in the solution of gold, and the zinc plate into the acidulated water. The power of the electric current may be moderated at will, by immersing more or less of the zinc plate, so that no hydrogen may be disengaged, and in this case the chloride of gold is alone decomposed. After a minute, the article to be gilt is withdrawn, wiped dry with a fine linen cloth, rubbed a little, and again immersed. After two or three immersions the metal will be found to be sufficiently gilded. (M. de la Rive.)

II. (*Process of M. Louyet.*) This consists in employing a strong solution of bisulphuret of gold in cyanuret of potassium and a powerful electric current. The bisulphuret is prepared by either passing sulphureted hydrogen through a solution of bichloride of gold, or by adding to a solution of the latter another of hydrosulphuret of ammonia.

II. Sassafras chips 1 lb.; ginger bruised 4 oz.; water 3 gallons; simmer until reduced to 2 gallons; then add treacle 16 lbs., rectified spirits 7 lbs., and laudanum 1 pint.

III. Opium ½ oz.; treacle 5 lbs.; boiling water 1 gallon; dissolve, and add rectified spirit ½ pint; oil of sassafras ½ dr.; cloves, mustard seed, of each ...; corianders and caraway seeds, of each 1 dr.; digest for a week.

IV. Caraway, corianders, and aniseed, of each ...; water 6 gallons; distil 5 gallons, and add treacle 28 lbs.; mix, then add laudanum 1 quart, and oil of sassafras 1 oz. previously dissolved in rectified spirit 1 gallon.

Remarks. The above forms are those commonly sent in the drug trade. This cordial is anodyne and narcotic, and is commonly given to children troubled with wind or colic. Its frequent and excessive use has sent many infants prematurely to the grave. Gray says, "*It is chiefly used to prevent the crying of children in pain or starving.*" The dose is ¼ of a teaspoonful and upwards, according to the age of the child.

CORDIAL, GOUT. *Prep.* Rhubarb, senna, coriander seed, sweet fennel seed, and cochineal, of each 2 oz.; liquorice root and saffron, of each 1 oz.; raisins 2½ lbs.; rectified spirit of wine 2 gallons; digest for 14 days. Used in gout and rheumatism. *Dose.* 1 tablespoonful to ½ oz. It is stomachic and slightly laxative.

CORDIAL, HORSE. *Prep.* Compound tincture of benzoin 1 pint; compound spirit of ammonia and sweet spirits of nitre, of each 8 oz.; mix; put up in Bateman's bottles, and seal them.

CORDIAL LEMON. *Prep.* Digest 2 oz. each of fresh and dried lemon peel, and 1 oz. of fresh orange peel in 1 gallon of proof spirit for a week; strain with expression, add clear soft water to reduce it to the desired strength, and lump sugar in the proportion of 2½ lbs. to 3 lbs. to the gallon. The addition of a little orange-flower or rose-water improves it.

CORDIAL, LOVAGE. *Prep.* Fresh roots of lovage 2 oz.; fresh roots of celery and sweet fennel, of each 1 oz.; essential oil of caraway ¼ oz.; proof spirit 3 gallons; digest for 7 days, add water 1 gallon; distil off 2½ gallons; add water to make it of the desired strength, and sweeten with sugar. To the above ingredients some persons add, before distillation, ¾ oz. of fresh valerian and 1 drachm of oil of savine.

CORDIAL, NERVOUS. (BRODUM'S.) *Prep.* Tinctures of gentian, calumba, cardamoms, and senna, compound spirits of lavender, and steel wine, of each equal parts. Tonic and stomachic.

CORDIAL, ORANGE. Like lemon cordial, ... fresh orange peel to the gallon.

CORDIAL, PEPPERMINT. *Syn.* SPORTSMAN'S CORDIAL. EAU DE CHASSEURS. *Prep.* Add English oil of peppermint 2 oz. to rectified spirit of wine 1 quart, agitate well in a corked bottle, capable of holding 3 pints or more, then pour it into a cask having a capacity of upwards of 100 gallons; add 36 gallons of perfectly white and flavorless proof spirit, agitate well for 10 minutes, then add 2 cwt. of the best refined lump sugar, previously dissolved in twice its weight of pure filtered rain water; rummage well, and further add sufficient clear rain water to make up the whole quantity to exactly 100 gallons; again rummage well; add 2 oz. alum, dissolved in 1 quart of rain water, and a third time agitate for 15 minutes, after which put in the bung and let it stand for a fortnight, when it will be fit for sale.

Remarks. The above produces a beautiful article, provided the oil of peppermint be of good quality, the sugar double refined and stove-dried, and the cask one that will not give color. To ensure the *first*, the oil should be purchased of some known respectable dealer. That prepared at Mitcham, Surrey, and hence called "*Mitcham oil of peppermint*," is not only the strongest but best flavored, and though more than double the price of the foreign oil, is, in the long run, much the cheapest. *The sugar* should be sufficiently pure to dissolve in a wine glassful of clear soft water, without injuring its *transparency*, and the *cask* should be a fresh-emptied gin pipe, or one properly prepared for gin, as if it give color it will spoil the cordial. If these particulars be attended to, the product will be a *clear transparent* liquor as soon as made, and will not require fining; but should there be the slightest opacity, some alum may be added as above, which will clear it down. Some persons add more oil of peppermint, others less, than the quantity I have ordered, but this, as well as the weight of sugar, must depend upon the taste of the purchasers, and the price the liquor is to be sold at. The product is 100 gallons of cordial at 64 u. p., which is the strongest usually sent out. A similar plan may be followed for the manufacture of any other cordial liquor, the same principles and operations being common to all.

CORDIAL, SIR WALTER RALEIGH'S. *Syn.* SIR W. RALEIGH'S CONFECTION. AROMATIC DO. *Prep.* Fresh summits of rosemary and juniper berries, of each 1 lb.; cardamom seeds, zedoary, and saffron, of each ½ lb.; proof spirit 1½ gallons; digest for a fortnight, express and strain; evaporate to 2½ lbs. and add Gascoigne's powder 1 lb.; cinnamon and nutmegs, of each 2 oz.; cloves 1 oz., white sugar 2 lbs., mix well together.

Remarks. The above formula is that for the original aromatic confection. Sir Walter Raleigh's own receipt was far more complicated.

CORDIAL, SPORTSMAN'S. *Syn.* EAU DE CHASSEURS. *Prep.* Peppermint water and rectified spirits of wine, of each 1 pint; lump sugar ½ lb. Dissolve the sugar in the water and add it to the spirit.

CORDIAL, WARNER'S. *Prep.* Rhubarb ℥j; senna ℥iss; saffron ʒj; liquorice root ʒiv; raisins lb. j; rectified spirit lb. iij: digest for a fortnight. Laxative.

CORK. *Syn.* CORKER. The lichen omphalodes made into balls. Used to dye wool.

CORKS. The common practice of employing inferior corks for the purpose of stopping the mouths of bottles, is often productive of considerable loss, from the air being only partially excluded, and the contents suffering in consequence. I once saw a large "*bin*" of valuable wine become, in less than a year, little better than sour Cape, from the parsimony of its owner on this point, and I have frequently had to regret the loss of valuable chemical preparations from a similar cause. The best corks are those called "*velvet corks*," and of these the finest qualities are imported from France.

tages, are united of the combination of the gold with the copper, and of an almost unlimited thickness of gold. (Comptes Rendus, July, 1843.)
